cent) There was an area of destruction along the outer margin of the trochanter, extending inward in varying distances to the femoral neck. The thickened bursa was sometimes apparent, when compared with the opposite side, and in some cases in which opaque material was injected the infected bursa became rather large. It has been our custom to take roentgenograms of the lungs in all cases of tuberculosis of the bones. In this series of cases the lungs were affected in eight (42 per cent), while in four (21 per cent) there was evidence of tuberculosis in other joints. In two cases (10.5 per cent) the urinary tract was affected. This large percentage of tuberculosis present elsewhere in the body and common injuries to the trochanters in falling and bruising during the active period of life readily demonstrates that injury to the bone may be an exciting or accessory factor in the production of tuberculosis in this region, secondary to a primary lesion in some other part of the body. In fifteen cases the roentgenograms disclosed positive evidence of involvement of bone, and this was confirmed by operation. In two other cases tuberculosis was found at operation to involve the trochanter when the roentgenograms apparently were negative. In two cases apparently the bursa only was involved, that is, no connection could be found leading to the trochanter. It is of interest that the wounds in these two cases healed by primary intention, whereas in cases in which the trochanter was definitely involved they healed slowly, or a sinus formed. The degree of involvement of the trochanter then may be looked on as an index to the difficulty in obtaining healing after operation.

The treatment of tuberculosis of trochanteric bursae and of the trochanter should be radical excision as soon as the diagnosis has been made. The type of operation preferred is total excision of the bursal sac and thorough curettement of the abscess in the bone, or excision of the involved portion of bone. Careful hemostasis and closure without drainage, and a compression pad and bandage all help to diminish the incidence of sinuses. In ten cases, because of the large size of the wound, we found it necessary to insert a small soft rubber drain to provide drainage of serum, which is bound to collect in such a cavity. The wounds were then sutured snugly with silk worm and non-absorbable dermal sutures. When the serous discharge had diminished the patient was exposed either to direct sunlight or to a sun lamp.

In this series of nineteen cases the focus was excised in seventeen, in one case the area was aspirated and material was obtained for study, and in one a discharging sinus was curetted. In only two cases were rice bodies found in the infected bursae. In two cases two operations were performed, and in six healing was by primary intention, in nine within a few weeks following the operation. Drainage persisted in four cases. Specimens of tissue taken at the time of operation proved to be tuberculous in all of the nineteen cases. In five cases in which guinea-pig inoculation was done, the results were all positive for tuberculosis.

As postoperative treatment, we have stressed the necessity of general upbuilding of the patient by proper diet, cod liver oil and heliotherapy, both local and general.

REPORT OF ILLUSTRATIVE CASES

CASE 1—A woman, aged 27, a school teacher, admitted to the Mayo Clinic Dec. 7, 1926 complained of a painful right hip and ankle. In 1918 she had had an attack of acute multiple arthritis and was in bed for eight months. She continued to have pain in the right ankle and hip. In 1922 the right ankle

had been operated on, and a diagnosis of tuberculosis was made. The exact nature of the operation was not known. Pam persisted and she wore a cast from the toes to the knee for one and a half years. In the meantime, a mass appeared over the lateral aspect of the upper third of the right thigh. This was operated on in June, 1923, the wound healed by first intention. Previous illnesses were unimportant and her family history was negative.

On examination the patient appeared to be fairly well developed but somewhat undernourished. A fluctuating mass was present over the right greater trochanter (fig. 1, A and B). There was free and painless motion of the hip. There was ankylosis of the right ankle probably postoperative arthrodesis. The right leg was 2 cm. shorter than the left. Ankylosis of the right sacro-iliac joint also was present. The thorax and abdomen were normal. The systolic blood pressure was 120 and the diastolic 80 in millimeters of mercury, the temperature and pulse rates were normal at 4 p.m. Urinalysis was negative. The estimation of hemoglobin was 68 per cent, the leukocytes numbered 9,100. The Wassermann reaction of the blood was negative. Roentgenograms disclosed destructive arthritis of the right sacro-iliac and right ankle joints. The region of the right trochanter was reported normal on roentgenographic examination. A clinical diagnosis of tuberculous bursitis was made.

An exploratory operation was performed December 11, and an enlarged bursa was found in the region of the right greater trochanter. The bursa was filled with necrotic tissue coagulated fibrin and thin watery fluid. It was connected with other bursae between the gluteal muscles. A specimen was sent to a pathologist, who reported tuberculosis. The patient was dismissed from the hospital on the fourteenth day with the wound healed. She was advised to continue antituberculous treatment.

In January, 1927, the patient entered the hospital at her home because of a discharge from the wound. A letter received in May 1928 stated that the wound was healed and that the ankle and hip were not giving her a great deal of trouble.

CASE 2—A farmer aged 44 admitted to the clinic, Dec. 26, 1922 complained of lumps over the right hip and thigh. Twenty-three years previously he had had some soreness and swelling in the region of the right greater trochanter. There was no local heat or redness, but pain was experienced when he tried to lie on the affected side. Apparently recovery from this attack was uneventful, and he had had no further trouble until about fifteen years previously when again swelling had appeared in the middle of the thigh posteriorly to the right. The swelling ruptured spontaneously and discharged a watery fluid, which contained white lumps like cottage cheese. The resulting sinus closed six months later and remained closed until the spring of 1922, when a lump appeared over the right greater trochanter. This was followed by the appearance of other swellings on the anterior and posterior surfaces of the thigh. Two weeks before he came to the clinic the swelling over the trochanter ruptured spontaneously and began to discharge. A diagnosis of a bone tumor was made. The patient had had dysentery and malaria in 1898. The family history was negative except that the father had died from nephritis.

The patient appeared to be well nourished. A sinus over the right greater trochanter was discharging. Motions of the hip were slightly restricted in all directions and there were fluctuating masses over the anterior and posterior surfaces of the middle of the thigh with no tenderness, local heat or redness. The right inguinal glands were enlarged. The heart and lungs were normal. The systolic blood pressure was 126 and the diastolic 74. The temperature was normal. The urine contained a trace of albumin. The leukocytes numbered 12,000 and estimation of hemoglobin was 77 per cent. The Wassermann reaction of the blood was negative. The tonsils were infected. Roentgenograms of the hip showed an erosion of the greater trochanter with some bony overgrowth and the roentgenologist made a diagnosis of tuberculosis (fig. 2). A clinical diagnosis of osteomyelitis of the right greater trochanter was made.

Aspiration and evacuation of the fluctuating mass was done Dec. 28, 1922. About 500 cc. of pus was aspirated from the largest abscess which was just above the greater trochanter. Jan. 10, 1923 the sinuses were again explored and two additional abscesses in the thigh were drained of broken down tuberculous material. The exact point of the origin of the sinus tract could not be determined although the finger could be inserted well up to the rim of the ilium. Five large iodoform packs were inserted

into the wound and were removed by the end of the ninth day. The patient was dismissed from observation, February 8, about one month following the operation. He had a serous discharge and was advised to take sun baths and so forth.

The pathologic examinations of secured tissue from the last operation disclosed inflammation. Culture of the material obtained at this time yielded negative results, and two guinea-pigs inoculated with the material were found to be tuberculous at necropsy.

A letter from the patient after he had returned to his home stated that the sinuses were all closed and that he was well.

CASE 3—A housewife, aged 31, came to the Mayo Clinic, Oct 26, 1926, because of a sinus and pain in the left thigh. She had been well apparently until 1918, when she began to have pain in the lateral aspect of the left thigh, with some tenderness. This trouble had continued until March, 1925, when a swelling appeared on the posterior aspect of the thigh just below the gluteal fold. The mass measured about 6 by 4 cm but gradually increased until, July, 1925, when it was incised by a local physician. The patient was in the hospital fourteen weeks with a Buck extension on this leg and then remained in bed at her home for six months. She said she had had fever every day. The sinus closed one week previous to her admission to the

bursa and bone, and then it ran anteriorly around the lesser trochanter downward and forward to the inner side of the femur. The tract, bursa and involved bone were completely excised. The wound was closed with two Penrose drains, which were removed in forty-eight hours. A pathologic diagnosis of tuberculosis was made. The patient was dismissed from the hospital on the sixteenth day with the wound healed by first intention. She has not been heard from since then.

CASE 4—A logger, aged 25, came to the clinic, Sept 19, 1929, because of osteomyelitis of the right hip. About three years previously he had been struck over the right hip by a log, considerable pain followed. A diagnosis of fracture was made at the time, and the hip was immobilized in a cast for about eight weeks but there was still some pain, and he limped. In February, 1927, the hip was operated on by his physician and a sequestrum removed. The operation was followed by a discharge from the wound. There was no history of tuberculosis in the family, and the patient had had no previous illnesses.

At examination there was a postoperative scar on the outer surface of the upper thigh, from a sinus which was discharging, and also a scar over the buttock. There was some limitation of motion at the hip, and roentgenograms gave evidence of old osteomyelitis of the greater trochanter of the right femur with

Fig 2—Tuberculosis of the greater trochanter of twenty three years duration

Fig 3—Tuberculosis of the left trochanter and bursa injected with Beck's paste

Fig 4—Tuberculosis of the right sacro iliac joint and right greater trochanter. There was a history of severe trauma in the region of the hip

clinic and this was followed by fever, nausea, headache and severe pain in the thigh. These symptoms were relieved after drainage had been established. The family history was negative, and the patient had had no previous diseases with the exception of influenza in 1925, appendectomy had been performed in 1911.

The patient appeared to be well developed and well nourished. There was tenderness over the left greater trochanter and a sinus in the left thigh just below the gluteal fold. A probe was passed into the sinus and from 12 to 14 cm toward the lesser trochanter. Motions of the hip were good and did not cause pain. Roentgenograms of the region of the hip were negative, however injection of the sinus with bismuth, October 20, disclosed a large sinus tract passing about the trochanter (fig 3). The thorax and abdomen appeared to be normal, although roentgenograms of the thorax disclosed evidence of an old healed lesion of apical tuberculosis on the left side. The systolic blood pressure was 120 and the diastolic 80, the temperature was normal and the pulse 88. The urinalysis was negative. The estimation of hemoglobin was 75 per cent and the leukocytes numbered 12,800. The Wassermann reaction of the blood was negative. A clinical diagnosis was made of tuberculosis of the bursa over the left greater trochanter and involving the greater trochanter.

November 1 exploration and excision of the sinus tract showed that the sinus tract ran from about 9 to 11 cm below the greater trochanter upward to it with involvement of the

multiple spicules of bone in the soft tissue and also destructive arthritis of the right sacro iliac joint (fig 4). The thorax and abdomen appeared to be normal. The systolic blood pressure was 120 and the diastolic 70, the temperature was 97 F at 1:20 p m, and the pulse rate was 88 a minute. The urine was normal except for an occasional pus cell. The estimation of hemoglobin was 92 per cent, and the Wassermann reaction of the blood was negative.

At operation, Sept. 23, 1929, the trochanter was chiseled off, the diseased tissue excised and the cavity packed with a strip of petrolatum gauze. On pathologic examination the specimen disclosed tuberculosis. September 30, daily treatments were begun of ultraviolet rays applied to the wound, together with infra-red. The patient was dismissed from the hospital, October 3. Some discharge was still present. Continued treatment with ultraviolet rays had practically healed the wound by November 19 at which time he was dismissed from observation. Roentgenograms taken after the operation disclosed tuberculosis of the sacro iliac joint, tuberculosis of the greater trochanter and loose bone particles, and overgrowth of bone at the margin of the acetabulum.

The patient reported by letter in August, 1931, that his leg was healed. In October 1932 he returned with swelling and a recurring sinus. The sinus was explored and curetted and a gauze pack inserted. General antituberculous measures, such

as heliotherapy, rest and cod liver oil, were advised for a prolonged period.

CASE 5—A woman clerk, aged 38, admitted to the clinic, April 8, 1930, complained of tight muscles and soreness about the right hip. A sister had died of tuberculosis twenty-five years previously, and her mother had died of carcinoma of the liver. The patient had had pneumonia at the age of 14 years and influenza at 26. The present trouble had started about fourteen years before her admission to the clinic with some soreness in the region of the right hip, which would last for

Fig 5—A extensive tuberculosis of the right greater trochanter of fourteen years duration. Involvement of the hip joint and loss of bone salts in the neck of the femur may be noted. B tuberculosis of the greater trochanter eleven months following operation. Involvement of hip joint may be noted.

one or two days. There were long intervals when she had no trouble. In October, 1928, she began to favor the right leg because of pain, this subsided and she had no more trouble until January, 1930, when the muscles of the thigh appeared to tighten as she walked. She could not lie on the right hip because of pain. At this time she started limping and she had used crutches for six weeks before her examination.

The patient appeared to be somewhat undernourished. There was no limitation of motion, although motion caused some pain in the right hip. There was some tenderness over the right greater trochanter. Roentgenograms gave evidence of extensive tuberculosis involving the greater trochanter and cystic formation; there was some atrophy of the neck of the femur and arthritis of the hip (fig 5 A). The systolic blood pressure was 140 and the diastolic 100, the temperature was 100 F at 10 a. m., and the pulse was 120. Rales were heard in the left upper lobe of the lung, roentgenograms disclosed tuberculosis of the left upper apex. The urine was normal. The estimation of hemoglobin was 59 per cent, and the leukocytes numbered 5,800. The Wassermann reaction of the blood was negative. A clinical diagnosis of tuberculosis of the right greater trochanter was made.

Operation was performed April 15. The cavity in the greater trochanter was explored and found to be filled with cheesy, broken down material. There was no free pus. Specimens were sent for guinea-pig inoculation and for pathologic examination. The cavity was swabbed with iodine and alcohol and the wound closed without drainage. The pathologist found degenerated tissue of an amyloid nature. The guinea-pig died; the test was positive for tuberculosis. Convalescence was uneventful, and, April 26, eleven days after operation, the wound was healed and the stitches were removed. A cast was applied from the thorax to the knee on the right side. The patient was dismissed from observation, May 2, and advised to take heliotherapy and cod liver oil and to use crutches.

The patient returned in July, as she had been instructed and the cast was removed. Roentgenograms disclosed improvement in the appearance of the neck of the femur and marked filling in of the bone in the cavity. She got along well until December 1 when she stumbled and fell. The right knee became swollen and painful and an abscess developed in the incision six weeks before she returned to the clinic, March 30, 1931. At this time she was recovering from influenza and had two draining sinuses. There was a good deal of limitation of motion of the right hip. Roentgenograms disclosed destructive arthritis of the hip. The patient was advised to go to a sanatorium for

treatment of tuberculosis of the lungs, and for complete of the hip (fig 5 B).

The patient died, Sept. 6, 1932, seventeen years after onset of her complaint.

CASE 6—A housewife, aged 44, came to the clinic, Jan. 1932, because of a draining sinus over the greater trochanter of the right femur of eight months' duration. At the age of 10 years she had received a blow on the right thigh above the knee, an abscess resulted, which was incised and drained. It healed easily, although she limped on the leg for many years. Later she received another blow, which was followed by fever and a discharging sinus in the thigh. She was given tuberculin by her physician and the wound continued to discharge for one year. Since that time four operations had been performed, and each time the trouble extended. When she was admitted to the clinic a discharging sinus was still present. She complained of weakness in the affected leg and constant soreness in the thigh. The family history was negative.

Examination disclosed numerous scars on the outer surface of the thigh with a small draining sinus below the trochanter. There was some limitation of motion at the hip. The heart and lungs were normal. The systolic blood pressure was 140 and the diastolic 90; the temperature was 98 F. The urinalysis was negative except for pus graded 4. Erythrocytes and leukocytes were normal and the Wassermann reaction of the blood was negative. Roentgenograms disclosed some destruction of the greater trochanter with a few small fragments of bone in the periarticular structures.

January 6 the sinus tract was excised. The tract led down to a large, old chronically inflamed sac, which was attached to the trochanter. This was dissected to the bone, where it was removed to its attachment over the trochanter. The whole sac, which was hard and sclerotic, was taken out. A diagnosis of tuberculosis was made by the pathologist (fig 6). Two small sequestrums that were in the fibrous tissue about the trochanter were removed. A rubber tube was inserted, the wound was

Fig 6 (case 6)—Tubercles seen in tissue removed at the time of operation.

loosely sutured and a gauze dressing saturated with alcohol was applied and covered with a cotton pad. The drain was removed in twenty-four hours. The wound healed by first intention. The patient now reports that the wound is in good condition and that she is taking heliotherapy.

SUMMARY

A study was made of nineteen patients with tuberculosis of the greater trochanter and the trochanteric bursa beneath the gluteus maximus, verified by opera-

tion, pathologic examination and, in five cases, guinea-pig inoculation

Evidence of tuberculous disease in other parts of the body was found in 73 per cent of the cases, 42 per cent of which was in the lungs and 31 per cent in other parts of the body

The symptoms were usually local and consisted of a cold, fluctuating swelling, local tenderness and, seldom, impairment of motion of the joints

Roentgenograms showed involvement of the trochanter in 78 per cent of the cases

The treatment advocated was early radical excision of the involved area, followed by adequate antituberculosis measures, such as rest, proper diet, cod liver oil, and heliotherapy, with special stress on the last mentioned

The prognosis is good with prolonged careful general treatment Without treatment, sinuses form and spread infection into the neck of the femur and hip joint

ABSTRACT OF DISCUSSION

DR FREDERICK C KIDNER Detroit This thorough paper calls attention to a rare condition and to the importance of diagnosis I have had only three cases of tuberculosis of the greater trochanter or its bursa Two of the cases were in children about 12 to 13 years of age, and in both a wrong diagnosis was made In one case the diagnosis was that of osteitis fibrosa cystica and in the other the diagnosis was of a cyst with a peculiar inflammatory reaction around the outer wall Operation was performed in both cases, which proved to be tuberculous Attempts at excision were made and were successful in that they relieved the symptoms but both patients had persistent sinuses The third case, that of an elderly man, made me doubt whether this disease originates in the bone The man was 60 years of age and had a large tumor over the trochanter This was fluctuant and the diagnosis was obscure The roentgenogram showed a little erosion of the trochanter itself Operation disclosed a large sac in which there were typical tuberculous masses Any connection with the trochanter itself was very difficult to find The changes as one examined the trochanter at the time of operation were those of pressure rather than of disease The bone was dense and hard but smooth In that case an effort was made to excise completely but was not successful, with the result that secondary infection set in and the man died after some months of the secondary infection These few cases lead me to believe that the complete removal of tuberculosis of the trochanter and its bursa is not an easy operation but still I believe that the attempt at such removal is the proper treatment

DR C A Stone St Louis Tuberculosis of the trochanter is not quite as rare as some think A number of these cases have been seen at the Washington University Dispensary in St Louis I want to stress one or two things In practically all I have found the disease present elsewhere I believe that trauma has considerable to do with it It is difficult to eradicate the disease in the trochanter just as it is difficult to eradicate it elsewhere It is worth while to pay attention to this disease For several years past the best of living conditions existed in the country the cities require that all their milk should be pasteurized a great deal has been done in the testing of cattle for tuberculosis and bone tuberculosis has decreased considerably I want to make it distinct that at this time living conditions have changed a great many children are undernourished and physicians must be on the lookout again for bone tuberculosis with the natural increase in the number of cases that take place in the greater trochanter

DR ARTHUR STINDLER Iowa City I wish to mention the work of Dr Milgram who has collected records of twenty or twenty-one cases of chronic inflammation of the gluteal bursa about half of which were tuberculous One case had been treated for scirrhia for about thirty years So far as I know all those cases have been relieved by the complete radical

excision of the bursa, as Drs Meyerding and Mroz have recommended, and I know of one case that has been under observation for several years It is our impression that the primary tuberculosis of the gluteal bursa, is, if anything, more important than the primary tuberculosis of the trochanter in extension on the bursa

DR HENRY W MEYERDING, Rochester, Minn I thought this series was worth reporting because of the scarcity of literature on the subject and because these patients were all operated on and the material removed from the site proved to be tuberculous I wrote Dr Z B Adams to find out what his experience had been He writes as follows 'I have had just your experience with the gluteal bursa which surrounds the trochanter and the tuberculous bursae, which we have opened and cleaned out, and have succeeded for a time in getting them healed up so that it seemed as if the disease was cured However, these cases have a way of recurring in the bony trochanter itself several years later, and these cases of tuberculosis of the greater trochanter we have treated by cutting out the Brody's abscess or the tuberculous bone, as far as we could, and packing them with grease, a la Orr These have healed up and gone on quite satisfactorily in some cases, although in some other instances, even when the removal of the whole trochanter has been necessary in order to get rid of the infected bone so far as possible the disease has slowly spread up the neck and then involved the hip joint' All our patients were mature We feel that no matter whether one operates or not, general anti-tuberculosis measures are really the important factors in obtaining a cure

Clinical Notes, Suggestions and New Instruments

STATUS EPILEPTICUS TREATED BY MAGNESIUM SULPHATE INJECTED INTRAVENOUSLY

FREDERIC STORCHHEIM, M.D. WAUWATOSA, WIS.

Status epilepticus, while not very commonly seen, is one of the gravest symptom pictures encountered by physicians According to Wechsler,¹ it 'generally ends fatally' The great majority of true status attacks, when the patient is unconscious and has epileptiform attacks, between which he does not regain consciousness, with the convulsions coming on with a half hour down to a few minutes or even several seconds between, terminate in death When the physician reaches the stricken patient the latter is usually flat on his back in deep coma breathing stertorously, with copious white froth escaping from his mouth and often from his nostrils The face may be pale or deeply cyanotic and the entire body wringing wet from perspiration The pulse is often extremely rapid, especially in the later stage, and of varying quality, and the respiratory rate is usually somewhat increased The breathing is handicapped by the large quantity of fluid in the air passages and in the lungs themselves The signs of pulmonary edema are very obvious in these victims

The medication advised for these patients in the standard textbooks is morphine, with atropine chloral, ether or chloroform anesthesia In my experience they have been entirely inadequate All my patients, five in number, with true status, who were treated thus, died The cases all had a common characteristic a frothy emanation from the mouth with the stertorous breathing signifying pulmonary edema There was a terminal rise of temperature to 104 or 105 F in four of these cases The pulmonary edema with the consequent or accompanying heart failure, was largely responsible for the fatal termination Therapy, in order to be successful, must apparently attack this phase

Instead of the older treatments mentioned which had proved to be of no value whatever, intravenous medication with magnesium sulphate was given for the treatment of status epilepticus thereafter Eight patients have been treated so far, among whom three patients have had two attacks from which

From the Milwaukee County Asylum for Chronic Insane
¹ Wechsler, L. S. A Textbook of Clinical Neurology, Philadelphia W. B. Saunders Company 1932 p. 616

they recovered, and one patient has had four attacks and is still alive. So far, no case of status, treated thus, has terminated fatally. It is believed that all these cases would have ended fatally similarly to the first series, if intervention had not been undertaken or if they had been treated along the same lines. The relief obtained was, however, purely symptomatic, as several of the patients have had status attacks again after the recovery from the first attack. In all instances, the relief from the signs of pulmonary edema was very striking.

It was noticed further that in more than half the cases there was an interval after an attack of status, during which the patient was free from convulsions much longer than ordinarily.

In two instances the dose of 10 cc of 25 per cent magnesium sulphate was decidedly inadequate. It was found safe and advisable to repeat the injection a third time, although more than that would have been, according to the work of Stander, very dangerous.

COMMENT

Lennox and Cobb³ state that all observers are agreed that during the seizure itself [epileptic seizure] spinal fluid pressure is greatly increased.⁴ Weed and McKibben⁴ demonstrated on animals that cerebrospinal fluid pressure and brain bulk may be varied by hypertonic and hypotonic salt solution. Peterman, in discussing convulsions in children, points out the significance of cerebral edema in epilepsy and advises the use of hypertonic solutions. Thus, the intravenous use of magnesium sulphate appears to be logical and rests on a sound physiologic basis.

Search of the *Quarterly Cumulative Index Medicus* as far back as 1917 does not reveal a report of the intravenous use of this drug in the treatment of status. Sodium amytal is widely used intravenously for this purpose, but it has the disadvantage that the patient sleeps for many hours afterward, and bronchopneumonia is to be reckoned with. My patients usually awakened within twenty minutes after an adequate dose had been given, from a condition which is known to be usually fatal, just as spectacularly as a patient in diabetic coma can be aroused by an adequate dose of insulin.

It is interesting to note the parallelism of thought in the medical treatment of eclampsia and status epilepticus. For both conditions, morphine, chloral or ether anesthesia and the like were recommended. In 1926, McNeile and Vruwink⁶ described the intravenous use of magnesium sulphate solution in the care and treatment of preeclampsia and eclampsia. They say "We frankly believe that we can usually depend on intravenous medication to prevent and control convulsions. During the convulsive state of a toxemia of pregnancy the intravenous injection of 20 cc of a 10 per cent solution of magnesium sulphate will generally stop or at least limit the number of convulsions." Perhaps it would not be surprising to find that the underlying pathologic changes of the central nervous system are analogous, if not identical, in status epilepticus and in eclampsia. The results of treatment of status by the intravenous use of magnesium sulphate are at least as favorable as in eclampsia. Possibly the influence of this substance on the edema of the lungs, as well as on the brain, may play an important if not the decisive role.

It is well known that magnesium sulphate given intravenously, must be given with caution, but the limits of safety, up to which magnesium sulphate may be injected intravenously, have apparently been well worked out. Fischer⁷ states that the salt may be safely used in a 2 to 25 per cent solution up to 8 Gm. Stander² has found on the basis of animal experimentation that, given in a 10 per cent solution 0.1 Gm per kilogram of magnesium sulphate intravenously represents a safe dose. Thus up to 7 or 8 Gm would represent the upper limit of safety.

CONCLUSIONS

1 True status epilepticus is ordinarily fatal unless adequately treated.

2 Magnesium sulphate solution given intravenously, if administered in adequate doses, apparently terminates an attack of status successfully and thus acts as a life saver.

3 An injection of 10 cc of a 25 per cent solution of magnesium sulphate is apparently a safe dose to give and terminates most attacks of status. If necessary, it may be repeated and possibly given a third time in a well developed individual. More is dangerous.

4 The trend of treatment of true status epilepticus has been very much like the medical treatment of eclampsia.

5 Pulmonary edema when occurring in status, is apparently successfully coped with by intravenous injection of magnesium sulphate.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONTRIBUTING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

AMINOPHYLLINE—Aminophyllin—A double salt or mixture of theophylline, $C_8H_{10}(CH_3)ON_2H_2O$, and ethylene diamine, $C_2H_4(NH_2)_2$, containing not less than 70 per cent of anhydrous theophylline (calculated to the dried specimen).

Actions and Uses—Aminophylline has the actions and uses of theophylline and theophylline-sodio acetate, over which it has the advantage of greater solubility. Like these it has a diuretic action, produces myocardial stimulation, and occasionally may be useful in relieving the pain of coronary disease.

Dosage—Orally, from 0.1 to 0.2 Gm, by rectal administration in the form of suppositories, 0.36 Gm, or, as a retention enema from 0.3 to 0.4 Gm dissolved in water, intramuscularly, 0.48 Gm, intravenously, in emergencies only, 0.24 Gm.

Aminophylline occurs as white or slightly yellowish granules possessing a slight ammoniacal odor and a bitter taste, soluble in water about 1 part in 5 parts at 25°C, insoluble in alcohol and ether. An aqueous solution is distinctly alkaline to litmus paper on exposure to air it gradually absorbs carbon dioxide with the liberation of theophylline.

Dissolve about 0.5 Gm of aminophylline in 25 cc of distilled water previously boiled to remove carbon dioxide and add with constant stirring 1 cc of diluted hydrochloric acid collect the precipitate of theophylline on a filter paper wash with cold water dry at 100°C it melts at from 267 to 272°C. Place about 0.01 Gm of the resultant precipitate in a porcelain dish add 1 cc of hydrochloric acid and 0.1 Gm of potassium chlorate evaporate the mixture to dryness on a water bath on inverting the dish over ammonia the residue assumes a purple color readily destroyed by fixed alkalis. To the filtrate from the foregoing add 2 cc of benzoyl chloride followed by the addition of 5 cc of sodium hydroxide solution agitate the mixture and heat gently for a short time and allow to cool collect the precipitate of ethylenediamine dibenzoate on a filter paper wash with water and dry at 100°C, it melts at 244°C.

Incinerate about 1 Gm of aminophylline accurately weighed the residue does not exceed 0.1 per cent. Dry about 1 Gm of aminophylline accurately weighed in a desiccator over calcium chloride for forty-eight hours the loss does not exceed 4.5 per cent. Transfer about 0.2 Gm of aminophylline, accurately weighed to a 500 cc Kjeldahl flask and determine the nitrogen content according to the Gunning method described in Official and Tentative Methods of Analysis of the Association of Official Agricultural Chemists, edition 3, 1930, page 20, chapter 2, paragraph 22, the percentage of nitrogen corresponds to not less than 32.2 per cent nor more than 33 per cent calculated to the dried substance. Transfer about 0.15 Gm of aminophylline to a 100 cc volumetric flask containing 5 Gm of sodium chloride and 10 cc of 20 per cent hydrochloric acid followed by the addition of 50 cc of tenth normal iodine solution finally dilute with water to the final volume of 100 cc and allow to stand for thirty minutes shaking at intervals filter through paper rejecting the first 20 cc of the filtrate measure accurately 50 cc of the filtrate into an Erlenmeyer flask and titrate the excess of iodine with tenth normal sodium thiosulphate solution using starch paste as an indicator the amount of iodine consumed multiplied by two and the conversion factor (0.004503 Gm) represents the amount of theophylline present in the specimen the percentage of theophylline found by this method should not be less than 70 per cent nor more than 83 per cent calculated to the dried substance.

NOTE—No satisfactory method for accurate determination of theophylline in theophylline-ethylenediamine has been found. The assay by the periodide method is only roughly approximate it is important that as nearly exactly the specified amount of aminophylline as possible be used with iodine because the solubility of the periodide precipitate varies. This assay method of standardization is therefore at best approximate and must be considered tentative until such time as more accurate analytic procedure is available.

Aminophylline-Pharmedic—A brand of aminophylline-N N R

Manufactured by the Pharmedic Corporation Brooklyn N Y No U S patent or trademark

Ampules Solution Aminophylline Pharmedic 0.24 Gm 10 cc

Ampules Solution Aminophylline Pharmedic 0.48 Gm 2 cc

Suppositories Aminophylline Pharmedic 0.36 Gm

Tablets Aminophylline Pharmedic 0.1 Gm

Aminophylline-Searle—A brand of aminophylline-N N R

Manufactured by G D Searle & Co Chicago No U S patent or trademark

Ampules Solution Aminophylline Searle 0.24 Gm 10 cc Each ampule contains aminophylline Searle 0.24 Gm benzyl alcohol 0.24 Gm in sufficient distilled water to make 10 cc

Ampules Solution Aminophylline Searle 0.48 Gm 2 cc Each ampule contains aminophylline Searle 0.48 Gm benzyl alcohol 0.04 Gm in sufficient distilled water to make 2 cc

Tablets Aminophylline Searle 0.1 Gm (1½ grains)

Metaphyllin—A brand of aminophylline-N N R

Manufactured by the Byk Guldenwerke Chemische Fabrik Berlin Germany (Adolphe Hurst & Co New York N Y distributor) U S patent 919 161 (April 20 1909 expired) U S trademark 252 503

Ampules Solution Metaphyllin 0.24 Gm 10 cc

Ampules Solution Metaphyllin 0.48 Gm 2 cc

Suppositories Metaphyllin 0.36 Gm Each suppository contains metaphyllin 0.36 Gm in a cacao butter base

Tablets Metaphyllin 0.1 Gm

CHLORIODIZED RAPESEED OIL—A Halogenated Rapeseed Oil—A halogenated addition product of rapeseed oil containing from 24 to 26 per cent iodine and from 7 to 8 per cent chlorine in organic combination**Actions and Uses**—In the form of an emulsion, chloriodized rapeseed oil is used as a roentgenographic opaque medium in urography**Dosage**—The amount of emulsion to be used is determined by the size of the cavity to be visualized Intravenous and intraspinal injections are contraindicated

Manufactured by the Dermatological Research Laboratories branch of the Abbott Laboratories North Chicago Ill U S patent 1 870 023 (Aug 2 1932 expires 1949)

Ampules Camprodol Emulsion 20 cc Chloriodized rapeseed oil 5 cc acaia solution (35 per cent) 5 cc and distilled water 10 cc

Chloriodized rapeseed oil is a yellow semiviscous oil having an alliacious odor and an oleaginous taste soluble in benzene carbon disulphide chloroform and ether insoluble in alcohol and water On exposure to air and sunlight it decomposes turning a brown color Specific gravity at 20 C from 1.2 to 1.3

Boil about 0.5 cc of chloriodized rapeseed oil and 20 cc of half normal potassium hydroxide alcoholic solution in a porcelain dish for about ten minutes evaporate the liquid on a water bath and ignite the residue Dissolve the residue in 10 cc of water filter the solution add 5 cc of nitric acid and 2 cc of silver nitrate solution to the filtrate collect the precipitate consisting of a mixture of silver chloride and iodide on a filter wash with diluted nitric acid and water percolate the precipitate obtained with 10 cc of diluted ammonium hydroxide several times a white curdy precipitate results on the addition of an excess of diluted nitric acid Mix 10 cc of chloriodized rapeseed oil with 50 cc of purified petroleum benzine a transparent liquid results

Dissolve about 1 cc of chloriodized rapeseed oil in 10 cc of chloroform add a few drops of phenolphthalein solution and 0.3 cc of tenth normal sodium hydroxide solution the liquid becomes red (limit of acidity) Shake 1 cc of chloriodized rapeseed oil with 50 cc of water allow the oil to separate filter the supernatant layer through a wetted filter the filtrate yields no more than a slight opalescence with 1 cc of diluted nitric acid and 1 cc of silver nitrate solution (soluble inorganic halides)

Ignite about 1 Gm of chloriodized rapeseed oil accurately weighed the residue does not exceed 0.01 per cent Transfer about 0.3 Gm of chloriodized rapeseed oil accurately weighed to a bomb tube determine chlorine and iodine contents by the modified Carus method Collect the insoluble residue of silver halide on a filter paper wash thoroughly with diluted nitric acid and water puncture the filter wash the insoluble material into a 250 cc glass stoppered Erlenmeyer flask using about 100 cc of previously filtered stronger ammonium hydroxide stopper the flask shake the flask and contents and allow to stand for one hour Collect the insoluble residue of silver iodide on a tared Gooch crucible wash with diluted ammonium hydroxide and water and dry to constant weight at 100 C the amount of iodine found is not less than 24 per cent nor more than 26 per cent To the ammoniacal filtrate from the iodine determination add 25 cc of potassium iodide solution and remove the ammonia by heating on a water bath collect the insoluble residue of silver iodide on a tared Gooch crucible wash with water and dry to constant weight at 100 C the amount of silver iodide found calculated as chlorine is not less than 7 per cent nor more than 8 per cent

BENZEDRINE—Racemic deoxy-nor ephedrine—Racemic benzyl methyl carbinamine—A synthetically prepared racemic mixture of bases having the formula $C_9H_{11}CH_2CH_2NH_2Cl$ **Action and Uses**—Benzedrine produces local effects similar to those of ephedrine Local application by means of a spray or dropper of a 1 per cent solution in liquid petrolatum or inhalation of the vapors of benzedrine or its carbonate produces shrinking of the nasal mucosa in head colds sinusitis vasomotor rhinitis hay fever and asthma Both benzedrine and its carbonate (the latter readily forms on exposure of benzedrine to air) are volatile**Dosage**—As a spray, a 1 per cent solution in liquid petrolatum, as an inhalant, one or two inhalations through each nostril at hourly intervals, has been recommended Continued overdosage should be guarded against, as this has caused restlessness and sleeplessness, but no serious reactions have been observed

Manufactured by Smith Kline & French Laboratories Philadelphia Pa U S patent 1 921 424 (Aug 8 1933 expires 1950) U S trade mark 272 377

Benzedrine Inhaler Each inhaler tube contains at the time of packing benzedrine 0.325 Gm oil of lavender 0.097 Gm and menthol 0.032 Gm

Benzedrine Solution Benzedrine 1 per cent oil of lavender 0.33 per cent in liquid petrolatum

Benzedrine occurs as a colorless mobile liquid boiling at 200-203 C with slight decomposition The specific gravity at 25 C is 0.931 The vapor pressure at ordinary temperature is relatively high and the substance possesses a strong basic odor and a burning taste It is soluble in ether and alcohol and slightly soluble in water

Place 1 Gm of benzedrine in an Erlenmeyer flask, add 50 cc of water and 5 cc of 40 per cent sodium hydroxide solution then add benzoyl chloride 0.5 cc at a time shake the flask after each addition add the benzoyl chloride until no more precipitate forms after an addition Recrystallize twice from 50 per cent alcohol solution dry the crystals the melting point is 134-135 C The nitrogen content of the benzoate by the micro Dumas method is not less than 5.70 nor more than 5.95 per cent

Transfer 0.5 Gm of benzedrine accurately weighed to a tared weighing bottle and place on the steam bath for one hour The residue is not more than 0.5 per cent (volatile compounds) Dissolve 1 cc of benzedrine in 10 cc of liquid petrolatum U S P N (anhydrous) no turbidity is produced (water)

Suspend about 1 Gm of benzedrine accurately weighed in 10 cc of water and titrate with half normal sulphuric acid using methyl red as an indicator the acid used corresponds to not less than 95 per cent nor more than 100 per cent of the base (1 cc half normal sulphuric acid is equivalent to 0.0675 Gm of base)

Determine carbon hydrogen and nitrogen by micro combustion methods The carbon should be not less than 79.7 nor more than 80.3 per cent the hydrogen not less than 9.6 nor more than 9.9 per cent and the nitrogen, not less than 10.2 nor more than 10.6 per cent

Benzedrine Inhaler

Transfer the cotton filling to a Kjeldahl distillation flask, add 250 cc of water and 1 Gm of sodium hydroxide distil 150 cc into 20 cc of tenth normal sulphuric acid titrate the excess acid with tenth normal sodium hydroxide solution the base is equivalent to not less than 0.305 Gm nor more than 0.360 Gm per tube

Transfer the solution from the titration to a separatory funnel extract with 30 cc of ether transfer the ether extract to an Erlenmeyer flask, add 2 cc of 40 per cent sodium hydroxide solution and 0.5 cc of benzoyl chloride and shake the flask and contents for ten minutes set aside for two hours add 0.5 cc of benzoyl chloride shake the flask and contents for ten minutes set aside at the end of two hours add 0.5 cc of benzoyl chloride shake the flask for ten minutes allow to stand on the steam bath until the odor of benzoyl chloride has disappeared remove the precipitate by filtration wash with cold water dry at 90 C the melting point is 130-135 C

Benzedrine Solution

Transfer an accurately weighed sample of benzedrine solution weighing about 15 Gm to a Kjeldahl distillation flask, add 5 Gm of water and 1 Gm of sodium hydroxide distil 150 cc into 20 cc of tenth normal sulphuric acid titrate the excess acid with tenth normal sodium hydroxide solution the base is equivalent to not less than 0.95 per cent nor more than 1.05 per cent

Transfer the foregoing solution to a separatory funnel and proceed to determine the melting point of benzedrine benzoate as outlined under Benzedrine Inhaler

ALLERGENIC EXTRACTS-LEDERLE (See New and Nonofficial Remedies, 1933, p 27)

The following product marketed in dilutions representing respectively, 0.0005 mg 0.005 mg and 0.1 mg of nitrogen per cubic centimeter, has been accepted

Fish Glue Allergenic Extract Lederle

The product marked 10 is prepared by boiling the heads of any common fish for one hour in rectified distilled water, for example 40 pounds of fish heads in 30 liters of water with 45 cc of glacial acetic acid The resulting extract is filtered while hot through cloth yielding 25 liters of fluid of sp 1.05 The extract is evaporated on a steam bath to 2 liters of thick residue representing the stock material from which simple saline dilutions are made

DIPHTHERIA IMMUNITY TEST (SCHICK TEST)
(See New and Nonofficial Remedies 1933, p 398)

Hixon Laboratories Inc Johnstown, Ohio

Diphtheria Toxin for the Schick Test (Diluted)—A diphtheria toxin prepared by growing diphtheria bacilli in broth aging and diluting with a solution containing sodium borate 0.36 per cent boric acid 0.53 per cent and sodium chloride 0.61 per cent The diluted toxin is of such strength that 0.1 cc (one dose) given intracutaneously constitutes one-fiftieth minimum lethal dose for a guinea pig of 250 Gm weight The product is marketed is ready for use no diluent being required Merthiolate 1:10,000 is used as preservative Marketed in packages containing sufficient material for 10 25 and 50 tests**STAPHYLOCOCCUS VACCINE** (See New and Nonofficial Remedies 1933 p 390)

The Gilliland Laboratories Inc Marietta Pa

Staphylococcus Vaccine (Albus and Aureus) (See New and Nonofficial Remedies 1933 p 390)—Also marketed in packages of one 5 cc vial containing 2,000 million killed bacteria per cubic centimeter

Committee on Foods

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING
REPORT RAYMOND HERTWIG Secretary

CONTAMINATION OF FRUITS AND VEGETABLES WITH TOXIC INSECTICIDE SPRAY MATERIAL

Fruits and vegetables are frequently sprayed with highly toxic material for destruction of insects or fungus. Residues of these sprays may remain on the foods as distributed for consumption or for use in preparation of canned or other prepared forms of fruits and vegetables and endanger public health.

Distributors of fruits and vegetables that may bear toxic spray material are obligated to remove such poisonous contaminations before they enter commerce for retailing to the public, or to warn food manufacturers who will use the products for preparation of manufactured foods of the possible presence of the spray residue. Food manufacturers using fruits and vegetables should take proper precautions either to assure the absence of toxic spray contaminations or their removal before the products are prepared or packed for consumption.

Food articles, in the interest of public welfare shall bear or contain no toxic contaminations that may endanger health. Fresh fruits and vegetables likely to have been sprayed should be carefully washed with adequate water or special solvent solutions before use. Washing, however, does not assure removal of all spray materials. Distributors of fresh fruits and vegetables and manufacturers of foods containing these products bear a serious responsibility to the public that their products as presented for consumption are entirely wholesome, carelessness or disregard of this public health responsibility is criminal.

REPORTING OF VIOLATIONS OF REQUIREMENTS FOR ACCEPTED FOODS

Physicians, sponsors of accepted foods, or others are urged to notify the office of the Committee of violations of the Committee's Rules and Regulations and General Committee Decisions for accepted foods. This cooperation will materially aid the Committee in its public welfare and health work in the field of foods. Submitted advertising violating requirements will be given prompt attention whether the sender identifies himself or not.

MINERAL SPRING, NATURAL OR ALKALINE WATERS

Mineral, spring, natural or alkaline waters are usually advertised with unwarranted claims as to their health values. These waters are often alleged to possess curative and medicinal properties.

Analyses of most of these waters do not disclose explanations or evidence for remarkable curative properties. In case of potable mineral waters their mineral content comprises traces only of commonly occurring salts present in substantially greater quantities in ordinary foods. In many cases the deceptive therapeutic claims are the result of hearsay and illusion, or of deliberate scheming to defraud. Mineral waters having therapeutic action, generally cathartic, usually contain salts such as sodium phosphate or magnesium sulphate. Such therapeutically active mineral waters come under the purview of the Council on Pharmacy and Chemistry.

Formerly, therapeutic properties were attributed to mineral waters containing lithium or possessing radioactivity. Such characteristics as radioactivity or the presence of lithium in drinking water have not been shown to have useful effects. Strongly radioactive waters may be distinctly harmful. Natural waters contain only traces of lithium. The fortification of waters with lithium salts has no rational foundation, larger doses of lithium may be dangerous.

Spring waters of low mineral content are not to be distinguished physiologically from ordinary potable tap or drinking

water, their properties for meeting the water needs of the body are the same. Drinking water should be pleasing to the taste and free from contamination that may produce disease. Therapeutic or curative claims for mineral waters that are not laxative are to be viewed with suspicion.

The daily water requirements for health cannot be defined with any degree of exactness as activity, temperature and other conditions influence the demands. Sufficient water should be taken with meals and between meals to satisfy thirst. Glutting the body with water is not justified. Under disease conditions the physician should prescribe the water intake.

Good bottled waters of uniform composition, of tested purity and freedom from pathogenic contamination at the source and protected from possible contamination during transit to the consumer have special usefulness, they serve as refreshing, pleasing drinking water with a maximum safety assurance and merit the support of popular and professional advertising appropriate for pure potable water.

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG Secretary

GERBER'S STRAINED STRINGLESS GREEN BEANS

Manufacturer—Gerber Products Company, Fremont, Mich.

Description—Strained cooked stringless green beans retain in high degree the natural vitamin and mineral values. The coarser fibrous material is removed. No added seasoning or sugar.

Manufacture—Stringless green beans grown from selected seed under company supervision are harvested at the proper state of maturity, promptly washed, inspected, cooked, sieved, canned and processed as described under Gerber's Strained Vegetable Soup (THE JOURNAL, July 22, 1933, p. 282).

Analysis (submitted by manufacturer) —

	per cent
Moisture	93.2
Total solids	6.8

Calories—0.2 per gram 6 per ounce

Ingredients, Minerals and Claims of Manufacturer—See Strained Vegetable Soup (THE JOURNAL, July 22, 1933, p. 282).

SUNBONNET FLOUR (BLEACHED) LASSIE FLOUR (BLEACHED)

Manufacturer—Federal Mill Inc., Lockport, N. Y.

Description—Bagged hard winter wheat 'standard patent' flour bleached.

Manufacture—Selected hard winter wheat is cleaned, scoured, tempered and milled by essentially the same procedures as described in THE JOURNAL, June 18, 1932, page 2210. Chosen flour streams are blended and bleached with nitrogen trichloride (one-eleventh ounce per 196 pounds).

Claims of Manufacturer—For bread baking.

VALUE BRAND EVAPORATED MILK

Packer and Distributor—John F. Jelke Company, Hillsboro, Wis.

Description—Unsweetened sterilized evaporated milk. The same as Jelke Good Luck Evaporated Milk (THE JOURNAL, July 29, 1933, p. 367).

SATURDAY, OCTOBER 21, 1933

MALNUTRITION IN CHILDREN

The Secretary of Labor, through the Children's Bureau, called a conference in Washington, October 6, to consider what the Children's Bureau appears to regard as a significant increase in malnutrition directly attributable to the current depression. Representatives of official and voluntary health and relief agencies and of the medical profession and allied workers were invited to this conference. Prior to the conference a meeting of a selected executive committee had been held, and considerable publicity had been given to the opinion of the Children's Bureau that increase of malnutrition among children constitutes a serious menace at this time. The title Child Health Recovery, applied to the program proposed by the Children's Bureau, implies notable deterioration in child health during the years of economic stress.

The report of the executive committee, as presented to the conference, stated that the objective of the conference is to locate undernourishment, to initiate plans to overcome existing conditions of malnutrition and to prevent its further occurrence by dietary and medical procedures. Cooperation is to be asked of state and local departments of health, education and welfare, of state and local relief administrations, and of state and local medical and dental societies. All these are to be asked to coordinate themselves under state, county and local committees. The program is to include consideration of families not on relief as well as those receiving relief. The term child is to cover the period from infancy through adolescence. The Children's Bureau is to prepare a record blank to insure uniformity of recording. Examinations are to be made of large groups of children. These examinations and the subsequent treatment of the undernourished are to be paid for out of federal relief funds.

The report of the executive committee was supported by the presentation of statistics from New York City, Massachusetts rural regions, a Philadelphia relief group, and Denver social agencies. A number of speakers, including the federal relief administrator,

supported the contention that the nation faces a significant increase in malnutrition among children. However, a number of experienced public health workers, among them an officer of the federal government, pointed out that objective standards on which a diagnosis of malnutrition can be based are not available and emphasized that statistical evidence in current morbidity and mortality rates does not indicate any widespread emergency, though conditions in certain localities are admittedly deplorable. Warnings were issued on the floor of the conference against attempting to sell the country a famine program, against a national hysteria, and against wasting money on medical examinations when undernourished children, so far as they can be identified in the light of existing knowledge, are already known to physicians, nurses and social workers, in a word, against making a hullabaloo. Doubt was expressed as to the wisdom of superimposing a complex new organization on competent local workers and thus meddling with local agencies. It was pointed out that the expense involved in the examination program would go far toward providing adequate food for all children on relief. It was also pointed out that some malnutrition is always present, that undernourishment is not confined to the poor, that this problem was not born in 1929, and that its consideration at this conference was merely another symptom of dumping on the national table at this time of practically every instance of individual need.

In the end, approval of the report of the executive committee was moved. A question from the floor raised the point as to whether this report, if adopted, was to be considered binding on state and local groups, and the chair replied that its adoption would put it in the status of a recommendation. The report was adopted by *viva voce* vote.

Thus the federal government seems to be sponsoring a so-called child health recovery program in the face of an opinion expressed by a representative of one of its important bureaus to the effect that no unusual emergency has been shown to exist, as well as other opinions that there is no evidence of child health deterioration. Therefore, by implication, the title Child Health Recovery is a misnomer. Men and women whose genuine interest in child health cannot be questioned and whose experience and ability entitles them to an opinion have expressed their conviction that the wholesale examination of children in the absence of any objective criteria for malnutrition would be a waste of time and money and would give only a mass of unreliable statistical data. Fortunately, the plan is now in the hands of the states, and the medical and dental professions will have a voice in state and local programs. At least two state medical societies, Pennsylvania and New Jersey, have developed programs for child health conservation in their respective states, both projects antedating that now proposed by the Children's Bureau. Their experience should offer suggestions and guidance.

to other state committees. It is to be hoped that all local committees, in outlining their plans for safeguarding child health, will heed the voices of those who point out the disadvantages of the proposed program as well as those who support the proposed plan. Deterioration of child health must not be permitted to occur, but pessimism and hysteria should not be allowed to undermine what appears to be a revival of confidence.

THE ANTISCORBUTIC POTENCY OF CERTAIN FOODS

The conquest of scurvy, a disease of mankind that has a recognized history of several hundred years, illustrates in almost dramatic fashion what modern science has accomplished for human welfare in general and for the practice of medicine in particular. When James Lind, surgeon in the British navy, published his classic on scurvy nearly two hundred years ago, it became clear that the malady was due to a lack of fresh food as distinguished from stale or preserved foods, such as sea biscuit, salt meats and dried vegetables. When Lind's treatise appeared it served, in the words of Hess,¹ to crystallize the conception of scurvy, which had been stretched out of all proportions to include an ever increasing conglomeration of clinical conditions. Scurvy had become the alpha and omega of professional routine, the catchword of the day, the asylum ignorantiae of the practical man. Into this chaos, as Hirsch expresses it, "the first beams of light fell when Lind's classic work appeared."

About twenty years ago, thanks to the elucidating contributions of animal experimentation, it was clearly shown that scurvy is caused by the lack of a dietary essential that presently became classed as a vitamin with the specific designation of vitamin C. The ability to make progress in subsequent years is attributable chiefly to the fact that certain animal species, notably guinea-pigs, are susceptible to a series of scorbutic symptoms almost exactly analogous to those of man. The possibility of producing experimental scurvy at will made it easy to study antiscorbutic measures. The enthusiasm for such prophylactic undertakings was heightened when the susceptibility of the bottle-fed infant to scurvy was clearly demonstrated. This happened after the pasteurization of milk began to become common as a means of safeguarding health against certain milk-borne diseases. Today the use of an antiscorbutic in the diet of artificially fed infants has become almost universal.

The most recent phase of the study of scurvy includes the brilliant demonstration that vitamin C, the antiscorbutic food factor, is a well defined organic chemical entity comparatively simple in nature. Its synthesis in the laboratory may actually be accomplished at any moment for several chemists are hot on the trail² of

the six carbon ascorbic acid $C_6H_8O_6$, endowed with the virtue of preventing the pathologic changes in organs and tissues exhibited when vitamin C is not adequately supplied along with the other essentials of the human dietary. The chemical identification of the vitamin has been accompanied by efforts at chemical assay instead of the more laborious biologic measurement of potency. Thus, several minutes' scientific study in the chemist's laboratory is destined to supply, with reasonable accuracy, information about foods that has in the past required several weeks of patient observation on animals. Recently, for example, British biochemists³ have made estimates of the ascorbic acid content—that is, the amount of vitamin C—in a considerable number of food materials and have compared the results with those obtained by biologic assays. The outcome is of practical interest in showing anew that cow's milk is incomparably poorer in ascorbic acid than are the familiar current antiscorbutics. For example, whereas the ascorbic acid content of milk varies from 0.019 to 0.025 mg per gram, the citrus fruit juices approximate from 0.50 to 0.75 mg. This means that it may require from 1 to 2 ounces of fresh cow's milk to afford the antiscorbutic protection inherent in less than 2 cc (less than half a teaspoonful) of orange or lemon juice. Even at its best, therefore, a milk diet calls for supplementation with an effective antiscorbutic. The choice is no longer limited as it was in the days when the North American Indians taught the explorer Jacques Cartier how to save the lives of his men with extracts of "pine needles."

Current Comment

GASTRIC ACHYLIA AND ANEMIA

It seems increasingly clearer, from the more recent studies on anemia, that some of the manifestations of this multiform disorder must be associated with more than one etiologic factor. Among the aspects that present themselves from this point of view, perhaps the most interesting and clinically important are the indications that the stomach may have a definite and significant connection with pernicious anemia. As stated recently,¹ the occurrence of achlorhydria in pernicious anemia, the supervention of the disease in man following gastrectomy, the marked therapeutic effects of products of gastric digestion and of preparations of gastric tissue are convincing evidence of the existence of this relationship. That achlorhydria is frequently associated with an anemia secondary in type is also attracting considerable interest. One outcome of the situation has been a growing number of investigations in which possible interrelations of gastric achylia and various types of anemias have been

examined. For example, some time ago Ivy, Morgan and Farrell² observed the occasional development of a spontaneous anemia in gastrectomized dogs and in dogs with a pouch of the entire stomach. They reported an increased tendency to anemia in gastrectomized female dogs that became pregnant. This they postulated as indicating that the gastrectomy had reduced the factor of safety in the dog and that the additional strain of pregnancy was sufficient to produce an anemia. In work done in the same laboratories, at the Northwestern University Medical School in Chicago, hemoglobin production and the qualitative changes in the blood picture were determined in gastrectomized dogs maintained at an anemic level after measured hemorrhages.¹ Evidently in the complete absence of the stomach there is a much reduced capacity to regenerate hemoglobin after hemorrhage. Liver feeding or administration of liver extract, which is so effective in pernicious anemia, offers no hematopoietic advantages in uncomplicated gastric achylia. Furthermore, the induced anemias fail even after long periods to exhibit the characteristic histologic pictures of the pernicious type. Mullen³, Dragstedt and Bradley⁴ have reached the conclusion either that the failure of the gastrectomized dog to develop pernicious anemia indicates that he is biologically different from man in this respect or that in man, as well as in the dog, achylia or gastrectomy, as the case may be, is only one of several interrelated factors in the etiology of this disease. That the gastrectomized dog has a markedly reduced hemoglobin regenerating capacity would seem to favor the latter view. In harmony with this they add, are the clinical observations that neither achylia nor gastrectomy in man is invariably followed by pernicious anemia.

THE EFFECTS OF CERTAIN FRUITS ON URINARY ACIDITY

Few fruits are good sources of energy in nutrition, and still fewer are important as sources of protein. The high recommendation of fruits as components of a well selected dietary must therefore be based on other considerations. The textbooks on dietetics see the significance of the fruits in their mineral constituents and their unique vitamin content. It has also been known for some time that, despite the presence of a considerable variety of organic acids in fruits, including formic, citric, malic, benzoic and succinic acid, many of them function as potential alkalis in the body. The fact that the acid citrus fruits could actually give rise to an alkaline urine seemed hard to comprehend at first. The organic acids are, however, burned in the organism, and the residual "ash" is alkaline in character. The property of preserving the "neutrality" of the body fluids has been lauded often to the point of charlatanism in promoting the use of certain fruits to combat so-called acidosis. Indeed, Henderson¹ has severely criticized some of the current misconceptions of the term itself. Not all organic acids are readily burned in the metabolism.

Benzoic acid notably remains intact when ingested in any form, it is excreted, conjugated with glycine, as hippuric acid through the kidneys. Tartaric acid also is not readily destroyed in the human organism. Each edible fruit really needs to be tested in the crucible of the body. For the citrus fruits and many others the facts have long been known.² A new study by Saywell³ from the Fruit Products Laboratory of the University of California at Berkeley brings conclusive evidence for the potential alkalinity of pears, peaches and apricots. They increase the alkalinity of the urine, decrease the output of urinary ammonia, and increase the alkali reserve of the blood. These are criteria of the potential alkalinity of a food. Significant, too, is the observation that about 95 per cent of the organic acids of the fruits studied was actually oxidized in the body.

THE ANALGESIC EFFECT OF JAUNDICE

After four years of observation, Hench⁴ has issued a report which justifies the inclusion of another clinical phenomenon in the list of the accepted but only partially understood general bodily effects of jaundice. He has encountered a number of patients the pain of whose primary condition was largely, and usually completely, relieved when jaundice appeared. The main interest of this observation is not in diseases of the liver but in such painful conditions as arthritis, fibrositis and sciatica. In some of the cases observed, the pain disappeared under the influence of icterus, although the patients had not taken any drug. Nor was the relief of pain in the accepted cases attributable to any of the many factors which may abruptly cause cessation of activity of chronic rheumatic disease: rest in bed, pregnancy, acute infection, an unrelated major operation, arsphenamine, heightened basal metabolic rate, vaso motor effects of surgical anesthesia, postoperative fever, or diet. Jaundice of the intrahepatic type, not obstructive jaundice, seemed to be the significant factor. Apparently there was usually a direct relationship between the degree of analgesia and the concentration of serum bilirubin. In some cases, however, the relief from pain preceded the appearance of an icteric tinge in the peripheral tissues. Further explanation of the mechanism involved must await further investigation, although there is some ground for believing that icterus may have a local sedative action on inflamed tissue or that it may be depressant to the nervous system. Likewise, the obvious therapeutic implications are as yet insufficiently founded to warrant dosing with bile salts for pain of any description, as Hench is careful to point out. The time may come when it may be possible "to repeat nature's miracle to provide at will a similar beneficence by the use of some nontoxic accompaniment of jaundice, effective in available concentration."

Association News

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks

The American Medical Association broadcasts on Tuesday and Thursday mornings from 8 55 to 9 o'clock, central standard time, over Station WBBM (770 kilocycles, or 389.4 meters)

The subjects for the week are as follows

October 24 When a Child Chokes
October 26 Shopping for Milk

There is also a fifteen minute talk sponsored by the Association on Saturday morning from 9 45 to 10 o'clock over Station WBBM

The subject for the week is as follows

October 28 What Is New in Infant Feeding

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION PUBLIC HEALTH ETC)

ALABAMA

Fifty Years for Slaying a Physician—Eugene J Burns, convicted of second degree murder several months ago for the slaying of Dr William H Godwin, Thomas, was sentenced to fifty years in the state penitentiary, September 18, newspapers report. A motion for a new trial was denied. In his first trial Burns was convicted of second degree murder and sentenced to twenty-five years' imprisonment. Dr Godwin died in 1931 from gunshot wounds, received when he answered a call to a vacant house.

Promotions at Alabama University—Recent promotions on the faculty of the University of Alabama School of Medicine include the following, newspapers announced

Emmett B Carmichael, Ph D, head of the department of physiologic chemistry to full professor

Dr Franklin S DuBois to professor of anatomy and head of the department

James O Foley, Ph D to associate professor of neuro anatomy

Thomas E Hunt, Ph D to associate professor of histology and embryology

Dr Gene H Kisler to associate professor of physiology and pharmacology

Marie C D Amour, Ph D to assistant professor of physiology and pharmacology

ARIZONA

Basic Science Law in Effect—The voters of Arizona, in a referendum election, October 3, approved the basic science act passed at the last regular session of the state legislature, and signed by the governor, March 18. Cult opponents of the act, principally chiropractors and naturopaths relying on a provision of the state constitution maneuvered a referendum on the measure, thus forcing it to lie inoperative pending the outcome of the election. Nonsectarian and osteopathic applicants for licenses in Arizona are examined and licensed by the board of medical examiners, but chiropractors are examined by the board of chiropractic examiners. Heretofore each board has been the sole judge of the credentials of applicants applying to it for licenses. But under the basic science act until after the basic science board is satisfied that an applicant demonstrates a comprehensive knowledge of the basic sciences neither licensing board can examine him. The basic sciences as defined by the act consist of gross anatomy, physiology, pathology, chemistry, bacteriology and hygiene. Persons now licensed to practice the healing art must obtain certificates from the basic science board if they desire to continue in practice but they may obtain certificates without examination if they apply to the board before January 1 and pay a fee of \$5. If any present licensee neglects to obtain a certificate by January 1 he must pass an examination in the basic sciences to obtain one. The basic science act makes it specifically the duty of every police officer, sheriff and peace officer to investigate all supposed violations of it and to report the facts to the proper prosecuting authorities and requires the attorney general and the several county attorneys to prosecute all violations.

CALIFORNIA

Rabies—Rabies in animals has increased in California, according to the bulletin of the state health department, September 23. Out of a total of sixty-six cases reported in August, forty-nine occurred in Los Angeles County. Other counties reporting cases were Contra Costa, Kings, Sacramento, San Diego, San Joaquin, Sonoma and Stanislaus.

Symposium on Heart Disease—The heart committee of the San Francisco County Medical Society will hold its fourth annual graduate course on heart disease, November 22-23. No fee will be charged. Sessions will be held at the San Francisco, University of California and Stanford University hospitals, and at the new headquarters of the department of public health.

Mussel Quarantine Extended—The California Department of Health has extended the quarantine on mussels to October 30, because cases of mussel poisoning continue to be reported. The quarantined area has also been extended to cover the entire coastal region from Monterey County to the Oregon line, excluding the bay of San Francisco. The sale or offering for sale of mussels is prohibited by the quarantine regulations.

Health Officers Elect—Dr Herbert F True, health officer of Sacramento, was elected president of the Health Officers' Section of the League of California Municipalities at the annual meeting in Santa Cruz, September 18-20. Speakers before the section and the league included Dr George G Reinle, Oakland, president, California Medical Association, on "The Medical Profession and the Public Health", Nina S Estill, San Francisco, "The Calcium and Phosphorus Problem and the Average Diet", Dr Ray Lyman Wilbur, "The Place of the Health Department in City Government," and Karl F Meyer, Ph D, San Francisco, "Acute Health Problems Which Affect California."

CONNECTICUT

The Summer Round-Up—More than 70 per cent of the 3363 children examined during the summer round-up season, October, 1932-July 1, 1933, had physical and dental defects, many of which were considered serious enough to be referred to their family physicians and dentists for correction, according to the Connecticut *Health Bulletin*. Seventy-seven per cent of all children registered by local committees attended the round-ups for complete examination, and at 31 of the 178 round-ups all the children registered were examined. These round-ups are sponsored by parent-teacher associations and the bureau of child hygiene of the state department of health.

FLORIDA

Society News—Dr William C Blake, Tampa, presented a paper on coronary thrombosis before a joint meeting of the Sarasota and Manatee county medical societies recently, in Sarasota. A motion picture on "Living Tumor Growth Cells" was shown before the Orange County Medical Society, August 16.

Immunization Clinics for Negro Children—A series of clinics to immunize Negro children against typhoid, diphtheria and smallpox has been opened by the Tampa health department under the direction of Dr James R McEachern, health officer. It is hoped that during the three months for which the clinics have been planned, at least 3,000 children will be treated.

Department of Public Health Created—Announcement is made of the creation of a department of public health in Miami, which began functioning, September 15. Formerly all matters pertaining to health were administered under the department of public welfare through the division of health. Dr George N MacDonell will be director of public health. He was chief of the division of health for three years prior to his resignation in 1929. Dr John W Shusler resigned as head of the department of public welfare, effective August 15, to resume private practice.

ILLINOIS

Society News—Dr Leonard F Weber, Chicago spoke before the DuPage County Medical Society, September 20 on dermatology. The St. Clair County Medical Society was addressed in Belleville, October 4 by Dr Willard F Arbuckle, St. Louis, on "Bronchoscopic Diagnosis of Pulmonary Disease," and in East St. Louis, October 5, by Dr Louis C Boslimiere, St. Louis. "Silicosis and Silicotuberculosis"—Dr Ralph Pemberton, Philadelphia, addressed a joint meeting of the fifth

councilor district of the Illinois State Medical Society and the Sangamon County Medical Society, October 5, on the control of rheumatism—At a meeting of the Williamson County Medical Society in Marion October 3, among others, Dr Frank J Jirka, state health officer, Springfield, discussed epidemic encephalitis—Dr Charles P Emerson, Indianapolis, spoke, among others, before the Vermilion County Medical Society, October 3 on "Lessons from Medicine of the Orient"—Dr John A Wolfer, Chicago spoke on "Surgical Management of the Jaundiced Patient" before the Peoria City Medical Society, October 3

Faculty Presents Program—Members of the staff of St Louis University School of Medicine presented a program before the Adams County Medical Society in Quincy, October 9, as follows

Dr Cyrus E Burford Nephropey and Ureterolysis as Conservative Surgery
Dr William T Coughlin Injuries to the Brain
Dr Ralph A Kinsella Encephalitis
Dr William E Leighton Evolution of Spinal Cord Surgery
Dr LeRoy Sante Radiation in the Treatment of Malignant Disease
Dr August A Werner The Sex Hormones

Alphonse M Schwittalla, S.J., Ph.D., dean of the school made an address at the banquet on the report of the Committee on the Costs of Medical Care

Chicago

Dr Jackson to Address Public Meeting—Dr Chevalier Jackson professor of bronchoscopy and esophagoscopy, Temple University School of Medicine, Philadelphia will address the Chicago Medical Society, November 1, at a meeting open to the public on "Bronchiectatic Septic Tank and Its Prophylaxis" This talk will be discussed by Drs Samuel J Pearlman and Carl A Hedblom Dr Jackson will also speak at a reception and dinner to be held in his honor in the dining room of the Medical Arts Club before the meeting His subject will be "Is It Advisable to Treat Post-Tuberculous Cicatricial Stenosis of the Larynx?" The dinner meeting is being sponsored by the medical society and its Aux Plaines branch with the Chicago Laryngological and Otological and Chicago Tuberculosis societies

Changes at Loyola University—With the opening of the autumn quarter, the following promotions on the faculty of Loyola University School of Medicine were announced

Drs Walter R Bayard Jerome W Hayden John C Vermeren Francis A Dulak and Burton T Gordon clinical associates in ear nose and throat
Dr Howard C Riordan clinical instructor in ear nose and throat
Drs Patrick H McNulty and Peter A Nelson Jr clinical instructors in genito-urinary surgery
Drs Jacob S Grove and Carl J Uthoff clinical associates in genito-urinary surgery
Dr Robert J Hawkins, clinical associate in obstetrics
Dr William M Hanrahan associate clinical professor of obstetrics
Drs Edward H Warszewski and Martin G Luken clinical professors of surgery
Dr Joseph T Meyer assistant clinical professor of surgery
Dr Lester E Garrison clinical associate in surgery
Drs Edward B Kalvelage Anthony J Linowiecki and John P Woitalewicz assistant clinical professors of surgery
Dr John B O Donoghue clinical professor of surgery

Transfers included those of Dr Leo J Latz from the department of neuropsychiatry to the department of medicine as instructor, and Dr John G Powers from the department of anatomy to the department of medicine as assistant New appointments were announced in THE JOURNAL, June 24, page 2024

Society News—The Chicago Society of Allergy was addressed October 16, by Drs Isadore Pilot and Isidor Harrison Tumpeo on "Focal Infection and Allergy" and "Hyperergic Response of Allergic Children to Infection," respectively—At a meeting of the Chicago Ophthalmological Society, October 16, Drs Agnes Beulah Cushman and Samuel I Meyer presented reviews of the 1932 literature on trachoma, tuberculosis, retinal detachment and intra-ocular tumors, and glaucoma respectively—The McDonagh Society for Clinical Research was addressed, October 20, by Drs Paul G Pomeroy, Ottawa, and Kamil Schulhof on "Treatment of Polyarthritides" and "An Alleged Mechanical Detector of Disease," respectively—The Chicago Gynecological Society was addressed at its fifty-sixth annual meeting October 20, by Gordon J Laing, Ph.D., on "The Medicine Man" and Dr William F Petersen "Meteorological Associations of Disease"—Dr Charles H Mayo, Rochester, Minn., among others addressed the Chicago Association of Commerce, October 11, on "Good Health Essential for Sustained Recovery"—A clinic was conducted before the Endocrine Club of Chicago at the Elgin State Hospital, Elgin August 16 by Dr James H Hutton, Chicago and Drs Charles F Read, David L Steinberg and John T Nerancy, Elgin

MARYLAND

Semiannual Meeting of Medical Faculty—The semiannual meeting of the Medical and Chirurgical Faculty of Maryland will be held at Point Lookout, October 22-23 with Dr Robert V Palmer, Avenue, presiding Speakers at the general meeting include Drs Frederick D Chapple, Hughesville, president Southern Maryland Medical Society, Alexius McGlannan, Baltimore, Walter D Wise, and Hon J Allan Coad, who will speak on "The Relation of the Medical Society to the General Assembly" The scientific program includes the following

Dr Albert E Goldstein A Study of Patients of the Prostatic Hypertrophy Age
Dr Herbert Schoenrich Consideration of the Venereal Diseases in Medical Practice
Dr Frederic V Heitler Peroral Endoscopy—Its Practical Application in Diagnosis and Treatment
Dr Jay Martin Effect of Nonspecific Desensitization in the Treatment of Disease
Dr Francis J Kirby Foreign Bodies in the Elbow Joint

MASSACHUSETTS

Changes at Tufts—Dr Benjamin Spector has been promoted to the head of the department of anatomy at Tufts College Medical School, Boston, newspapers announce Other changes include the appointment of Dr Attilio Canzanelli as assistant professor of physiology, Dr Max Ritvo as assistant professor in radiology, and Dr Harold A Chamberlin as professor of urology

Society News—Drs Arthur W Allen and Benjamin H Ragle Boston discussed pitfalls in surgical and medical diagnosis respectively, before the Essex North District Medical Society, October 18 at Andover Dr William H Robey, Boston president of the state medical society, also spoke—At a meeting of the Greater Boston Medical Society, October 3 Dr Moses Paulson Baltimore spoke on "Present Status of Idiopathic (Chronic Nonspecific) Ulcerative Colitis"—Dr Howard M Clute Boston spoke on the diagnosis and treatment of obstructive jaundice before the Franklin District Medical Society, Greenfield, September 12

MICHIGAN

Society News—Tumors of the ovaries was the subject discussed at the meeting of the Michigan State Pathological Society, October 4, in Detroit—Dr Loren W Shaffer, Detroit addressed the Saginaw County Medical Society, September 19, on the modern treatment of syphilis—Dr Bruce H Douglas Northville was elected president of the Michigan Tuberculosis Association, September 20, succeeding Dr Henry D Chadwick, who recently became health commissioner of Massachusetts Dr Douglas was appointed to succeed Dr Chndwick as controller of the tuberculosis division of the Detroit health department

MINNESOTA

County Society Opposes Rezoning—At a meeting, September 18, the City Council of St Paul considered a petition to rezone the property at Hamline and Capitol avenues to enable "certain people to operate what would have been known as the Hamline Clinic and Hospital" Senator George L Siegel, representing the petitioners, stated that he was appearing for one Mr J J Hicks, who is interested in the sale of "Terpezone" machines for the treatment of tuberculosis and other respiratory ailments The rezoning was opposed by counsel for the Ramsey County Medical Society, the state board of medical examiners and the Ramsey County Public Health Association When it became evident that the council was not in favor of the proposition Mr Hicks withdrew his petition The Minnesota State Board of Medical Examiners believes that the use of "Terpezone" to treat patients with tuberculosis or any other ailment constitutes the practice of healing and as such, if used at all can be used only by one licensed to practice medicine and healing in the state The Council on Pharmacy and Chemistry of the American Medical Association found Terpezone unacceptable for inclusion in "New and Nonofficial Remedies"

MISSISSIPPI

Society News—Speakers before the Delta Medical Society at Belzoni, October 11 included Drs James A Wadlington, Belzoni and Andrew M Wynne, Merigold on "Glandular Therapy in the Treatment of Functional Menstrual Disorders," and Atebrin and Plasmochin in the Treatment of Malaria," respectively—Among others, Dr William A Land DeKalb, addressed the East Mississippi Medical Society, Philadelphia,

recently, on angina pectoris—Dr Joseph A Crisler, Jr, Memphis, among others, spoke before the Northeast Mississippi Thirteen Counties Medical Society in Calhoun City, September 19, on "The Decision for Surgery in Borderline Hypertension"—At a meeting of the South Mississippi Medical Society in Laurel, September 14, the speakers included Dr Shirley C Lyons, New Orleans, on "Treatment of Varicose Veins and Varicose Ulcers by the Injection of Sclerosing Solutions"

MISSOURI

Symposium on Encephalitis—Epidemic encephalitis was the theme of a symposium held at a special meeting of the St Louis Medical Society, September 1. Dr William G Patton discussed the recent epidemic and the Metropolitan Health Council, Dr Paul J Zentay, historical review, Dr Joseph F Bredeck, epidemiology, and Dr Howard A McCordock, pathology. The clinical features were discussed by Drs John W Eschenbrenner, Jr, Lee Pettit Gay, Goronwy O Brown and Andrew B Jones, Dr Ralph S Muckenfuss spoke on research and etiology. These presentations were discussed by Drs James P Leake and Charles Armstrong of the U S Public Health Service, William D Collier, Hollis N Allen, Theodore C Hempelmann, Arthur H Deppe and Walter A Younge.

Society News—Speakers before the Buchanan County Medical Society in St Joseph, September 6, included Drs Daniel G Stine, Columbia, on neurasthenia, Elmer T McGaugh, state health officer, differential diagnosis of encephalitis, and James P Leake of the U S Public Health Service, encephalitis. At a meeting of the Cass County Medical Society, September 14, Drs Basil O Hartwell, Drexel, and George W Griffith, Garden City, among others, spoke on tularemia and spinal cord tumors respectively. Dr Leith H Slocumb, St Louis, discussed the treatment of hemorrhoids before the Gasconade-Maries-Osage County Medical Society at Owensville, recently, and Dr Paul C Schnoebelen, St Louis, diseases of the colon. Among others, Dr Winton T Stacy, St Joseph, spoke on toxemias of pregnancy before the Randolph-Monroe County Medical Society at Moberly September 12. The St Louis Medical Society was addressed, September 19 by Drs Neil S Moore on "Transurethral Correction of Bladder Neck Obstruction," and Helmut H Kramolowsky, "Urological Diagnosis." Dr John R Caulk gave a motion picture presentation of a new cautery punch.

NEBRASKA

Society News—Drs Joseph A Henske and Clayton G Weigand, Omaha addressed the Otoe County Medical Society, Nebraska City, October 9, on practical pediatrics. Dr Howard L Updegraff, Los Angeles, will address the Omaha-Douglas County Medical Society, Omaha October 24, on "Reconstruction of the Burned Face." Speakers at the meeting October 10 were Drs G Alexander Young on "Symptoms and Treatment of Cases Seen in the Present Epidemic of Encephalitis," James Dewey Bisgard "The Fate of Transplanted Bone," and Frederick W Niehaus, "Cardiac Therapy."

NEW YORK

District Meeting—The seventh district branch of the Medical Society of the State of New York held its twenty-seventh annual meeting at Rochester, September 21. Scientific addresses were presented by Drs Royd R Savers of the U S Public Health Service on silicosis, Charles Gordon Heyd, New York, jaundice, Earl R Kirklin, Rochester, Minn, diagnosis of pulmonary tuberculosis, Arthur J Bedell, Albany, medical ophthalmoscopy, and Fred H Albee, New York, bacteriophage in wound treatment.

New York City

First Harvey Lecture—Dr Rolla E Dyer of the U S Public Health Service, Washington D C, delivered the first Harvey Lecture of the season at the New York Academy of Medicine October 19 on Typhus and Rocky Mountain Spotted Fever in the United States.

Hospital Appointments Available—The Hospital for Joint Diseases announces that six appointments for two years rotating service will be available three to begin July 1 1934 and three to begin Jan 1 1935. Graduating students and graduates (unmarried men) of class A medical schools are eligible. At the completion of the two years graduating interns are eligible for the following positions: (1) a residence in orthopedic sur-

gery with maintenance and salary of \$25 a month for the first year and \$50 a month for the second year, (2) the Frauenthal Travel Scholarship of \$2,400 a year for six months' study in Europe and six months in the United States and (3) the Mr and Mrs Frederick Brown Research Fellowships providing an award of \$2,400 each to two successful candidates. Applicants must register before December 15 and an examination will be held at the hospital, December 27.

Society News—Dr Donald Gordon will address the New York Surgical Society, October 25, on "Disabilities Following Trauma of the Extremities." Dr Henry E Sigerist, Baltimore, gave an address on "The Medical Profession Through the Ages" at the New York Academy of Medicine, October 18. Dr Walter B Cannon, Boston, addressed the Society for the Advancement of Gastro-Enterology, October 4, on "The Relation of the Nervous System to the Function of the Smooth Muscle." Drs Irving S Wright and Abram Wilbur Durvee addressed the Medical Association of the Greater City of New York, October 13, on "Therapy of the More Common Peripheral Vascular Diseases" and "Present-Day Methods of Diagnosis and Study of Peripheral Vascular Disease," respectively. George L Clark, Ph D, professor of chemistry, University of Illinois, Urbana, addressed the New York Roentgen Society at the New York Academy of Medicine, October 16 on "The Application of Roentgen Rays in Nonmedical Fields." The Physicians and Allied Professional Political League was recently organized for the purpose of furthering public legislation and measures indispensable to the welfare of the medical and allied professions. Dr George H Bigelow, Boston, addressed the Medical Society of the County of Queens, September 26, on "Fads and Fancies of Health." Dr Edward M Livingston gave an afternoon lecture before the society, October 6, on abdominal pain.

NORTH CAROLINA

Society News—Dr John F Brownsberger addressed the Buncombe County Medical Society, Asheville, August 21, on "Hydrotherapy and Physiotherapy in Medicine and Surgery."

New Dean at State University—Dr Charles S Mangum, professor of anatomy at the University of North Carolina Medical School since 1905, has been appointed dean to succeed Dr Isaac H Manning, resigned. Dr Mangum, a graduate of Jefferson Medical College, Philadelphia, has been associated with the university for thirty-seven years having served as professor of physiology and materia medica for nine years before his appointment in anatomy. Dr Manning had been dean since 1905 and had also previously served several years as professor of physiology. He will continue as professor of physiology. Dr Manning is this year president of the Medical Society of North Carolina.

NORTH DAKOTA

Personal—Dr Harry D Benwell, Grand Forks, has been appointed special lecturer in physical diagnosis in the University of North Dakota School of Medicine and Dr Donald B Simonson, instructor in physiology and pathology.

OHIO

Health at Columbus—Telegraphic reports to the U S Department of Commerce from eighty-five cities with a total population of 37 million, for the week ended October 7, indicated that the highest mortality rate (158) appeared for Columbus and the rate for the group of cities 98. The mortality rate for Columbus for the corresponding week of 1932 was 115 and for the group of cities 98. The annual rate for eighty-five cities for the forty weeks of 1933 was 109 as against a rate of 111 for the corresponding period of last year. Caution should be used in the interpretation of weekly figures as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have large Negro populations may tend to increase the death rate.

Cleveland Academy News—A new section on practice of medicine was inaugurated by the Cleveland Academy of Medicine October 11 with addresses on hypochromic anemia by Dr Russell L Haden and on treatment for pernicious anemia by Drs Harold H Brittingham and Harley A Williams. The society has announced a competition for interns for the best report of a case or of research work submitted to a committee of the clinical and pathological section. The winners will present their reports orally at the annual meeting of the section, December 1 which has been designated "Intern Night." A course of lectures on diseases of the gastro intestinal tract has

been arranged by the academy to begin October 27 and continue on Fridays to April 13. This is the second course of the kind sponsored by the academy. The registration fee is \$1. Dr. Richard Dexter is chairman of the committee in charge.

OREGON

State Medical Meeting at Portland—The fifty-ninth annual session of the Oregon State Medical Society will be held in Portland, October 26-28, at the Hotel Benson. At the opening general session there will be a symposium on cancer of the breast by Drs. Frank R. McInne, Warren C. Hunter and John Earl Else, all of Portland. The second day will be devoted to discussion of medical economics as follows:

Dr. Samuel G. Henricke, Portland: A New Deal in the Relationship of the Physician to Organizations Rendering Free or Part Pay Medical Care.

Mr. Clyde C. Foley, executive secretary of the society: The Ability of the People of Oregon to Pay for Medical Care.

R. W. Nelson, president Oregon Council of Hospitals: Experiments in Hospital Insurance.

R. R. Jackson, claim agent Oregon State Industrial Accident Commission: Medical Phases of Workmen's Compensation from the Viewpoint of the Commission.

Dr. Roscoe C. Leland, Chicago: Director Bureau of Medical Economics American Medical Association: The Insurance Principle in the Practice of Medicine.

Dr. Eugene P. Owen, Portland: The Aims, Organization and Operation of Professionally Controlled Group Health Associations.

At the final general session speakers will be Drs. Karl H. Martzloff, on 'Functional Uterine Bleeding'; Joseph A. Pettit, "Practical Points in the Diagnosis of Lesions of the Oral Cavity"; Thomas M. Joyce, Small Intestinal Tumors; and Goodrich C. Schaeffer, An Unusual Paralytic Syndrome in Pregnancy. All these speakers are residents of Portland. The medical and surgical sections will hold their meetings Thursday afternoon, October 26. The annual golf tournament will be played Saturday afternoon followed by a dinner at the Multnomah Golf Club. At the annual banquet Friday evening, Stephen B. L. Penrose, D.D., president of Whitman College, Walla Walla, will make an address on 'The First American Doctor of the Pacific Coast'.

PENNSYLVANIA

Hospital News—Dr. Maurice C. Pincoffs, Baltimore, delivered an address at Mercy Hospital, Pittsburgh, September 26, on "Clinical Aspects of Abrupt Rises in Blood Pressure." The occasion was a celebration of 'Mercy Day'—Citizens of Berwick oversubscribed a campaign for \$35,000 to prevent closing of the Berwick Hospital, July 20.

State Medical Election—Dr. Moses Behrend, Philadelphia, was chosen president elect of the Medical Society of the State of Pennsylvania and Dr. Donald Guthrie, Sayre, was installed as president at the recent annual session in Philadelphia. Vice presidents were elected as follows: Drs. George C. Yeager, Philadelphia; Charles W. Eisenhower, York; William G. Tillman, Easton; and George B. Woods, Washington. Dr. Walter F. Donaldson, Pittsburgh, was reelected secretary for the fourteenth year. The next meeting will be held in Wilkes-Barre.

Philadelphia

University News—Dr. Jacob Parsons Schaeffer, professor of anatomy, Jefferson Medical College, was the speaker at the opening of the eighty-fourth annual session of the Woman's Medical College of Pennsylvania, September 20. His address was on "The Scope and Method of Modern Anatomy in the Medical Curriculum." New appointments at the college include: Drs. Helen K. Grace, assistant in clinical gynecology and bacteriology; and Regina M. Downie, assistant in clinical gastro-enterology.

Society News—Drs. George E. Pfahler and Peter J. Kapó presented a paper on 'Treatment of Cervical Adenitis by Means of Roentgen Rays' before the Philadelphia Roentgen Ray Society, October 12. Drs. Joseph B. Wolfe and Harold F. Robertson presented an address on 'Experimental Air Embolism' with motion pictures among other speakers at a meeting of the Pathological Society of Philadelphia, October 12. The Philadelphia Pediatric Society is offering an award of \$100 for the best original study pertaining to pediatrics, submitted by a physician.

RHODE ISLAND

Personal—Dr. John Champlin Jr., Westerly, was elected chairman of the state public health commission for the next two years at the biennial session in September. The commission rotates the chairmanship among its members. Lester A. Round, Ph.D., was reelected state director of public health.

Society News—Drs. Frank A. Cummings and Isaac Gerber addressed the Providence Medical Association, October 2, on 'The Colon as a Focus of Infection' and 'Primary Carcinoma of the Lung,' respectively. Dr. Louis E. Phaneuf, Boston, addressed the Washington County Medical Society, Westerly, October 11, on 'Pelvic Inflammation in Women.'

VIRGINIA

State Medical Meeting at Lynchburg—The sixty-fourth annual session of the Medical Society of Virginia will be held in Lynchburg, October 24-26, under the presidency of Dr. James Carroll Flippin, University, with headquarters at the Virginia Hotel. Drs. Dean Lewis, President American Medical Association, and Louis Hamman, both of Baltimore, will be guest clinicians and speakers at the opening general session Tuesday evening, October 24. A symposium on diseases of the stomach will be presented Wednesday morning by Drs. William R. Bond, Richmond, who will speak on physiology of the stomach; Blanton P. Seward, Roanoke, differential diagnosis; Alexander F. Robertson Jr., Staunton, medical treatment; Charles Bruce Morton, University, surgical treatment. Among Virginia physicians who will appear on the program are:

W. Ambrose McGee, Richmond: Importance of Body Build in Determining Ideal Weight.

William H. Goodwin, University: Endometriosis with Reference to Intestinal Implants.

John L. K. Flannagan, Salem State: Medicine Problems.

Caleb S. Stone, University and Hubert B. Holsinger, Farmville: Diagnosis and Treatment of Gas Bacteria Infections.

Frank S. Johns, Richmond: Surgery of the Biliary Tract.

Marshall J. Payne, Staunton: Early Diagnosis of Primary Malignant Bone Tumors in Early Life.

John Shelton Horsley Jr., Richmond: Further Observations on the Continuous Intravenous Injection of Dextrose in Ringer's Solution.

Thomas W. Murrell, Richmond: The Problem of Hair Growth.

John A. Pilcher Jr., Roanoke: Management of Cross Eyes in Children.

Robert P. Hawkins Jr., Clifton Forge: Ureterosigmoid Anastomosis.

The Virginia Pediatric Society will hold its annual meeting at a luncheon, October 25, with Dr. James A. Lyon, Washington, D.C., as guest speaker on diagnosis and treatment of rheumatic heart disease in children.

GENERAL

Society News—Dr. John M. Wheeler, New York, was installed as president of the American Academy of Ophthalmology and Otolaryngology, and Dr. Wells P. Eagleton, Newark, N.J., was chosen president elect at the annual meeting in Boston in September. A silver platter was presented to Dr. Secord H. Large, Cleveland, who completed twenty-five years as controller of the academy.

Change in Status of Licensure—The Pennsylvania Board of Medical Examiners reports:

Leigh B. Shiffer, Easton: license reinstated August 30. The license had been suspended July 1, 1926.

The Board of Medical Examiners of the State Education Department of New York has recently reported the following action on licenses:

Dr. William A. Robison, Medina: license revoked in February case appealed to a higher court.

Dr. Louis H. Pincus, Yonkers: license suspended in April for one year for fraud and deceit in practice in connection with a cancer cure.

Bequests and Donations—The following bequests and donations have recently been announced:

Friends Hospital, Philadelphia: \$10,000 by the will of Mrs. Alice H. Yarnall.

Hahnemann Hospital, Philadelphia: \$5,000 from the estate of the late Miss Alice Hancock.

Woman's Homeopathic Hospital, Philadelphia: \$5,000 from the will of John W. Shuler and a deferred bequest of \$10,000 from that of Alice Hancock.

Phoenixville Hospital, Phoenixville, Pa., and Pottstown Hospital, Pottstown, Pa.: \$10,000 each by the will of Samuel P. Heister on the death of his daughter in law, Mary B. Heister.

Montgomery Hospital, Norristown, Pa.: \$5,000 by the will of the late Dr. William G. Miller for a free bed in memory of his brother and a \$10,000 trust fund for a William C. Miller room.

House of Rest at Sprain Ridge, Yonkers, N.Y.: \$5,000. Northern Westchester Hospital, Mount Kisco: \$3,000 under the will of the late Mrs. Florence Macy Sutton.

Montefiore Hospital, New York: \$25,000 and Mount Sinai Hospital, New York: \$10,000 by the will of the late Michael Gernsheim.

CORRECTION

Prolapse of Intestine Through Opening in Omentum—In a clinical note in THE JOURNAL, September 16, Dr. Antonio Gentile considered the case which he reported to be the seventeenth of its kind in medical literature. It has been called to his attention now that Dr. Edward H. McLean reported a similar case in *Northwest Medicine*, April 1932, page 193. Dr. Gentile's case would therefore be, he says, the eighteenth case of this kind in the literature.

The Noise Evil Organized Action at Last

The ill effects, on the well as on the sick, of the noises of modern civilization, particularly those due to automobiles, have been pointed out from time to time. The evil has reached such a pitch that at last corporate action is being taken. A new society called the Anti-Noise League has been formed by some well known public men, including leaders of the medical profession—Lord Horder, Sir James Purves-Stuart (neurologist) and Dr Dan Mackenzie (laryngologist and otologist). The league states that there is need for immediate action to mitigate the noise evil, especially the unnecessary hooting of automobiles in residential areas. They aim at enlisting such a force of public opinion as will induce the authorities to regulate by law forms of noise that are manifestly injurious to the comfort, health and repose of the community at large, as well as being damaging to efficiency and to the amenities of numerous urban localities. They invite all who suffer from the infliction of unnecessary noise to communicate with them. The ordinary membership fee of the league has been placed at the nominal sum of 30 cents.

Another important movement with the same end has come from the British Association for the Advancement of Science. At the recent annual meeting valuable papers were read describing the progress that has been made in the reduction of noise, especially in connection with aircraft. The association set up a committee to consider noises that it is most important to reduce and to collect information available for this purpose. Members of the public are invited to send their considered opinions as to the noises that cause them most discomfort and inconvenience to the honorary secretary, who is a professor of engineering. The committee can then select the subjects that appear to be of greatest importance and collect and review the knowledge available. It will in most instances be possible to indicate the amount of improvement that can be effected without serious loss of efficiency. If sufficient funds are available from manufacturers, it is hoped to arrange a practical demonstration at the meeting of the association next year.

A Medical Council Bill for All India

An all-India medical council bill has been passed by the legislative council of India to secure a uniform standard of qualification for physicians throughout India and to arrange for reciprocity abroad. As reported before the General Medical Council of Great Britain (the body that controls medical education and qualification for practice) in 1930 withdrew recognition of Indian medical qualifications, because it was not satisfied with the standard of examination and was refused facilities for inspection. As India was in a ferment of political agitation to a large extent anti-British the politicians ignored the good reason for the council's withdrawal of recognition and represented it as simply a slight by the British on India. The resentment aroused has taken the form of retaliation in the present bill which provides that if after the lapse of four years recognition of Indian qualifications is still refused British physicians may no longer practice in India. It may be pointed out that Indian physicians continue to practice in Great Britain and that those who have British qualifications have exactly the same legal status as Englishmen. The withdrawal of the recognition of Indian qualifications only forbids the registration of qualifications obtained in India since 1930 and prevents their holders obtaining the legal rights of qualified physicians in Great Britain. To all intents this means only the loss of power

to sue for debts for medical attendance and inability to sign death certificates. If such persons desired to practice they could do so on the same terms as osteopaths and other unqualified practitioners. Of course in a dependency of no other great power in the world could such a proposal as comes from India be possible.

Centenary of the Birth of Charles Bradlaugh

Lord Horder, who is president of the Birth Control League and leader of the movement in the medical profession, proposed the memory of Charles Bradlaugh at a dinner to celebrate the centenary of his birth. Bradlaugh may be regarded as the pioneer of birth control in this country. Lord Horder said that his handling of birth control left scarcely anything to add even after fifty years. By clear thinking and lucid expression, Bradlaugh made great contributions to the subject. What had been done since? In 1930 the Manchester police seized copies of a book called "Parenthood" with intent to prosecute the author and publisher. It was written by a competent London physician and the review, which stated that the book should meet the need of a good practical handbook on birth control with reliable data was quite a fair presentation. The process of law made possible all legal anachronisms, given sufficient stupidity on the part of the citizens who actuated these processes. Only three years ago no one could obtain any advice on contraception at any maternity center or hospital in the country that was state aided. After considerable pressure and faced with the terrible problem of maternal mortality, the ministry of health sanctioned the giving of such advice, but only in the case of women suffering from organic disease and in cases in which the bearing of children was likely to endanger life. The dissemination of that knowledge to the industrial classes which Bradlaugh rightly considered essential, was still denied though that knowledge was open to the well to do and the educated.

Automobile Accident Due to Effect of Insulin

The case was reported some time ago of a physician who was convicted of driving an automobile while under the influence of alcohol. He had diabetes and his defense was that his condition was due to insulin treatment. He appealed against the conviction but died from the disease before the case came on again. Insulin has now been the cause of conviction, without any question of alcohol. A man with a clean record as a driver drove his automobile almost at a walking pace between two lines of traffic and collided with three vehicles on the off side. The drivers shouted at him but he did not stop. He then collided with a stationary van, his car skidded and he came to a standstill on the pavement. A policeman found him in a dazed condition only partly conscious of what was said to him. He had diabetes and the police surgeon certified that he was under the influence of insulin and unfit to drive a car. Dr George Graham an authority on diabetes, gave evidence that the patient would generally have ample warning of any reaction from insulin and that his condition on the day of the accident might be due to the fact that improvement was taking place more quickly than he realized. The physician pleaded guilty to the charge of driving while under the influence of a drug which is an offense under the road traffic act. He was fined £1 and ordered to pay \$42 costs and his license was suspended for five years, but he was informed that he might apply for revision of the suspension after six months if he was medically fit.

Failure of Claim for Fracture of Jaw in Extraction of Tooth

The annual report of the London and Counties Medical Protection Society contains what is considered an important test case in that it establishes that, however careful an operator

may be, fracture of bone may occur. During the extraction of a septic third lower molar tooth from a woman, the jaw was fractured horizontally backward from the apex of the tooth. The patient was removed to a hospital, where the fracture was set. After her discharge she consulted her lawyers, who wrote to the dentist claiming damages. The matter was investigated by the dental experts of the society, who were satisfied that the methods of the dentists were in every way satisfactory, and it was decided to repudiate liability. At the trial the verdict was given for the dentist. The judge in giving judgment said that in his opinion the defendant had done everything that he possibly could, before and during the operation, to prevent such an occurrence, and that what had happened was through no fault of his.

Undulant Fever in France

Malta fever has become a disease with ever increasing incidence. Cases are developing today in nearly every part of France. Of particular importance is the article of Ranque and Senez pertaining to the serodiagnosis of the disease. In their laboratory at Marseilles, from 1919 to 1932, they diagnosed 2,800 cases of undulant fever originating in the Provençal region of France. They performed 16,000 Wright seroreactions and conclude that this test constitutes the surest means of diagnosis if it is positive at 1:400 or above, emulsions of cultures of *Micrococcus melitensis* titrated and then sterilized by iodine being employed. If the serodiagnosis is negative on the fifth day of an infection, undulant fever can be ruled out. In the doubtful cases, a second test should be made ten to fifteen days after the first. Undulant fever, which, in this region, showed a rapid increase up to 1929, has since then become less common. The curve of monthly morbidity reveals, for each of the twelve years, a marked recrudescence toward the end of the winter and during the spring. The endemic foci are gradually becoming smaller and show a tendency to shift toward the north. Morbidity in man and abortions in animals continue to follow a frankly parallel evolution. Alimentary contagion appears to be much less frequent than contagion through contact, which at present is the most common form. Undulant fever tends to become more and more a disease occurring chiefly in farm laborers. At a session of the medical society of Marseilles, devoted to this subject, D. Olmer emphasized two points: 1. A negative sero-agglutination does not exclude the diagnosis of undulant fever. 2. Undulant fever, while widespread in the rural sections, is comparatively rare at Marseilles and when it occurs it is more commonly in the vicinity of the abattoirs. According to J. Pieri, quinine bismuth iodide is a chemotherapeutic treatment that has given good results. Benoit moved that this disease be classified among the occupational diseases. The medical society of Marseilles adopted a resolution to that effect. J. R. Paillas reported the case of an adult, who had suffered from undulant fever for eight months, the disease having failed to yield to any of the therapeutic measures employed, but who recovered after an intestinal hemorrhage. It is possible that the shock was a factor in this recovery. Mr. Roger also is convinced that direct contamination through contact with sheep or goats is at present much more frequently the cause of undulant fever than the consumption of milk or cheese. At Tunis, Dr. Setbon tried hypodermic injections of milk derived from goats known to be infected. He administered this milk, sterilized, in doses of 2 cc. for children and 5 cc. for adults, increasing the dose to 10 cc. or more according to the age and the tolerance of the patient. As a rule from eight to ten injections suffice—given daily if they are well borne otherwise at wider intervals. The reactions are mild and rare.

Mr. Vidal has remained faithful to the treatment that he has used for many years, which consists of intravenous injections of arsphenamine, in doses of from 0.004 to 0.006 Gm., administered twice a week, which gave 80 per cent of good results.

The Work of the Grancher Society

Dr. Armand Delille, general secretary of the *Oeuvre Grancher*, founded in 1901 by Grancher, recently rendered an account to the academy on the present status of this foundation, whose range of activity is increasing year by year. It counts at present chapters in forty-five departments of France. In 1932, the forty-five chapters selected 6,000 children who were still healthy but who had been exposed to tuberculous contagion by a bacillus-ferous parent. In order to be accepted, the roentgenograms of children must not reveal any parenchymatous or glandular changes. The children taken from their homes are placed in healthy peasant families until the disappearance of the cause of familial infection, where they are under the regular supervision of health officers of the foundation. The *Oeuvre Grancher* relies chiefly on private contributions for its support and, while it receives subsidies from the central government, these constitute a small proportion of its budget. The results accomplished by the society tell their own story. Morbidity from tuberculosis among the children taken from homes is low (0.3 per cent) while the mortality from tuberculosis is under 0.1 per cent. Placement in families is much less expensive than placement in institutions and contributes effectively to a restoration of their strength.

International Congress of Nurses

The International Congress of Nurses, which comprised representatives from twenty countries, assembled recently in Paris, under the chairmanship of Mlle. Chaptal, founder of the training schools for nurses, in France, and today president of the international committee of nurses. Mr. Danielou, minister of public health, presided at the opening session. There were addresses by Prof. Leon Bernard, Dr. Jules Renault, Marquis de Lillers (vice president of the league of Red Cross societies), Miss M. Musson (president of the general council of the nurses of England and Wales), Miss Anny Brandt (German deaconess) and others. Another session was presided over by Miss Clara Noyes, director of the nursing service of the American Red Cross. An afternoon session was devoted to the study of the following questions: the profession of nurse and mental hygiene, the morale of the nursing profession from the legal point of view, the responsibility of the nurse as compared with that of the physician, the proportion of nurses with relation to the population and the extent of territory, the effects of the universal economic crisis on the nursing profession. The congress closed with a visit by its 2,500 participants at the Hôpital Foch, a model hospital that is being erected at the gates of Paris overlooking the magnificent panorama of the Bois de Boulogne and Paris. The hospital is reserved for the middle classes: scientists, artists, civil service employees, retired army officers and the like. The hospital comprises eight stories and has 300 rooms with modern equipment, a maternity clinic, an isolation pavilion and a training school for nurses that will accommodate 150 pupils. The congress was then transferred to Brussels, where its sessions were continued. Before their adjournment the conventionists decided on the erection of a memorial to the nurses of France which will be placed at Pierrefonds, where a French nurse, Mlle. Jalaguier, was killed during the war.

Georges Hayem's Death

Prof. Georges Hayem died, at Paris, from an attack of pleurisy, at the age of 92. Born in 1841 he had a brilliant career, becoming in quick succession hospital physician and professor at the Faculté de médecine. In 1886 he was chosen a

member of the Academy of Medicine, of which he later was president. His clinical lectures, held in the Hospital St Antoine, were attended, up to the time of his retirement, by a large group of French and foreign students. He was an excellent clinician, but in his publications he always assigned an important place to the laboratory. His researches on the blood are still widely read. He was the father of modern hematology. In spite of his age, he continued in vigorous health and never missed a session of the academy. He had a magnificent old age (exempt from infirmities), in which he found pleasure in devoting himself to the engraving of medallions, an art in which he displayed unquestionable talent. He executed a large number of medallion portraits of his most eminent confreres.

Estimation of Duration of Treatment

Because of the expense involved, the Krankenkassen are interested in determining the average duration of clinical treatment. While, for various reasons, such estimates must be looked on with great caution, it may not be out of place to give some of those found in recent reports of investigations of the Krankenkassen. The average duration of hospitalization and convalescence following uncomplicated surgical operations, according to these computations, is from eight to ten days. In appendicitis, without abscess formation, dismissal from the hospital can be effected on the tenth day, at the latest. In operations for hernia, a hospital stay of about fourteen days and incapacity to work extending over from three to four weeks can be expected. In operations on simple goiters, eight days of sickness need not ordinarily be exceeded while the regaining of working capacity will require from two to three weeks. Removal of tumors of the breast necessitates from eight to ten days for completion of the healing process, and the restoration of working capacity requires generally about four weeks, from the beginning of treatment, without postoperative irradiation. In operations on the stomach, dismissal from the hospital can usually be effected about three weeks after the operation. In uncomplicated cholecystectomy, the clinical treatment is completed two weeks after the operation, in drainage of the common duct, in about three to four weeks. The clinical after-treatment in hemorrhoidal operations lasts about two weeks. The deduction appears justified that in typical surgical interventions, the hospitalization can usually be limited to from two to three weeks. The duration of treatment in urologic disorders is usually longer owing to the fact that more than a single organ is involved. In urologic cases, early hospitalization nearly always proves to be good economy because many superfluous measures commonly employed in ambulant therapy can be omitted. As approximate values of the duration of hospitalization one can assume in renal calculus with bilateral involvement 683 days in men and 867 days in women, unilateral nephrolithiasis 283 days in men and 334 days in women, ureteral calculus 251 days vesical calculus 268 days, pyelonephritis, 29.45 days perinephritis and periureteritis 33.45 days urinary infections in female patients with dysuric symptoms 27.5 days, urethral stricture 50.3 days renal tuberculosis, 53.6 days hydronephrosis 31.5 days renal tumors 23.1 days, benign bladder tumors 38 days cancer of the bladder, 40.9 days cancer of the prostate 55.1 days, and hypertrophy of the prostate 40.36 days.

The New State Medical Academies

For years some cities of Germany had what were called "sociogenic academies" which served for the special training of district physicians, communal physicians and panel physicians. In place of all these academies two state medical academies

have been created, one in Berlin and one in Munich, which are under the direction of the Prussian ministry of the interior and the state commissar for the public health service in Bavaria, respectively. These two academies will be opened in November and will constitute the recognized institutions in which all physicians who are in the public service will, in the future, be trained for their new duties in the fields of racial biology and demographic science. The academies will likewise give continuation courses in all fields of medicine connected with the fulfilment of national tasks. The director of each academy will appoint a manager and a directive council. Concerning the further tasks of the academies, the following information has been offered. Formerly, the individual's welfare was the keynote of the physician's activities. There developed the struggle of "all against all," which resulted in misery for the mass of the people. A more enlightened view and a prompt return to the firm foundations of the state will insure our extrication from this state of wretchedness. This prospect opens up new problems for the whole medical profession, which shall regard itself henceforth not so much as a liberal profession but as a profession that has tasks to fulfil in the service of public health. This applies more particularly to the physicians who are in the public service. The physicians must raise the new thoughts and ideas of people and nation, in the sense of a natural community of persons closely related by race and psychic characteristics, from the depths of unconscious feeling and transmute them into a principle by which to guide their practical and political conduct, for a firm government presupposes the existence of a cultured people free from hereditary taints. This goal requires the introduction of new forms of education and schooling. It is with these thoughts in view that the state medical academies have been established and equipped.

Since a certificate showing regular attendance at this institution of higher learning must be presented by all candidates for district physician and also for the communal and the welfare service, only such applicants will be considered as have acquired the necessary preliminary training in a state medical academy. A guaranty is furnished that only such applicants will be accepted as state and communal physicians as are fairly familiar with the requirements of national public health administration. A special course of study is planned for each semester, the courses extending over a period of three months. The first course of the state medical academy of Berlin, which has the character of a college will comprise race hygiene and demographic science, general social hygiene, special welfare work in connection with the public health service and social pathology, organization and administration of social services and the laws pertaining thereto, protection against air and gas menace, drill courses, practical welfare work and inspections.

Convalescent Serum for Treatment of Poliomyelitis

An announcement of the Prussian ministry of the interior states that it has been decided to continue the arrangements provided for the securing, keeping in stock, storing and dispensing of serum of convalescents from poliomyelitis. It was recommended that experts be summoned immediately in order to establish as quickly as possible the nature of suspected cases of the disease and that the indications for the use of the serum be determined by consultants acting in an honorary capacity. This method proved its value in Hamburg in 1932. With regard to the preparation of the serum it was recommended that the blood donors needed be supplied by a special organization. As far as possible only the serum of persons who recovered from a manifest poliomyelitis from five weeks to three months previously should be used. Provision should be made for compensating the donors. In case of an increased demand for

serum, two large serum laboratories will keep considerable supplies of convalescents' serum in stock ready for shipment. The blood group to which the patient as well as the donors belong must be precisely established. The district physician should interest physicians in this therapy by lectures and other suitable publicity measures. In the case of patients who are already in the paralytic stage, great caution must be exercised in the use of serum, because of the danger of exacerbation. The intravenous and intralumbar routes should not be employed for the injection of serum. The scientific institutes throughout the country are requested to take up researches concerning the dissemination of poliomyelitis by healthy virus carriers, the duration of infectiousness of patients, the possibility of the transmission of an infection by food products and the relative action of serums derived from patients after the lapse of varying periods since the attack of the disease.

Antivaccination Societies Disbanded

As is well known, in spite of the evident excellent results of compulsory vaccination against smallpox, as prescribed by law in the German reich, there is still a group of persons vigorously opposing vaccination against smallpox. The ministry of Saxony has recently disbanded the antivaccinationists societies, including the Impfgegner-Aerztebund in Dresden for the territory of the state of Saxony, and has prohibited, at the same time, all public activities in opposition to vaccination against smallpox. A penalty will be imposed on any person who actively opposes such vaccination. The headquarters of the disbanded societies are being closed and all their equipment is being confiscated.

Number of War Injured Entitled to Aid

This year's census of the war injured and the survivors of participants in the war gave a total of 808,574 war injured entitled to receive aid. The number of war injured, which in 1931 numbered 838,360, decreased from 1931 to 1932 by about 18,000, and from 1932 to 1933 by 11,829. The decrease was due chiefly to deaths (8,912). The number of survivors who receive pensions and special aid amounts now to 893,582. The number of widows shows a slight decline. The number of orphans shows, as was expected, a further marked decrease.

Welfare Aid for the Sick

During the calendar year 1931 (or, in some cities, during the fiscal year 1931-1932), weekly benefits to the sick were granted by forty-one cities if the income did not exceed from one and one-half to two times the amount of general welfare aid and by five cities if the income did not exceed from two and one-half to three times the amount of general welfare aid, other cities followed other plans. In twenty-three cities the weekly benefits of the Krankenkassen were paid out in the welfare centers for gravidas and puerperants. In nineteen cities arrangements were made with midwives in connection with the discovery of gravidas. Courses of instruction for expectant and young mothers were given in only thirty-nine cities. In the follow-up infant welfare service, family welfare workers were employed in seventy-three cities and special welfare workers in twenty-one cities, contact having been made by the service with 77 per cent of the new-born. Young children were sent by seventy-six cities to recreation centers, young children received supplementary meals in fifty cities. The tuberculosis welfare service performed nearly 700,000 medical examinations and about 440,000 roentgenologic examinations and referred about 123,000 examinees to attending physicians and to therapeutic centers. Out of about 185,000 persons who appeared at the consultation centers for venereal patients, 35 per cent were found to be ill. In each thousand inhabitants, 31 persons were being cared for at the end of the year by the

welfare aid service for venereal patients. Of the persons cared for by the welfare aid service for cripples, 13 per cent were more than 18 years old, 83 per cent of the persons summoned for examination appeared in the centers of the welfare aid service for cripples. Eight per cent of the alcohol addicts cared for were women. Only nineteen cities had special welfare arrangements for cancer patients. Forty-four cities have welfare aid services in the hospitals, of these, twenty-five have special consultation centers. Whereas in the other branches of the welfare aid service the management is chiefly in the hands of physicians, here independent welfare workers predominate, in twenty-one cities about 55,000 consultations were given. The marriage consultation centers were used to only a slight extent. Consultation centers for athletic sports, which were established at first in sixty-six cities, had to be abandoned in ten cities. In thirty-three cities these consultation centers were available for every one but in other cities there were restrictions, some being intended only for members of athletic associations. Examination fees were exacted for marriage consultation and consultation in venereal disease in only one and three cities, respectively and for consultation on athletic sports in twelve cities. In seventy-four of these cities the reported branches of the welfare aid service required the expenditure of 27,500,000 marks (nearly \$10,000,000 current exchange), about 40 per cent of which was for personnel.

BELGIUM

(From Our Regular Correspondent)

Aug. 25, 1933

The Brussels Medical Convention

The thirteenth session of the Journées médicales de Bruxelles was devoted to the subject of syphilis. Monday and Tuesday mornings were given over to clinics or to demonstrations in hospitals and clinics. On Sunday and on Monday and Tuesday afternoons papers were read at the University of Brussels. The queen attended the opening session, and Count Carton de Wiart gave the address of welcome to the foreign delegates. Recalling that he presided, in 1921, at the first session of the Journées médicales the minister pointed out that the organizers, who wished to bring about a closer relation between practitioners and investigators, had realized their purpose. After exalting the medical profession as the most noble and useful of the professions, he outlined the program of the thirteenth session. The minister of health surveyed the results secured by syphilology, to which the Belgian scientists Bordet and Gengou made important contributions. Not only through research has Belgium contributed to the crusade against syphilis but also through an energetic national campaign. The opening session closed with an address by Mr. Charles Sarolea, which dealt with the physician and medicine in European literature. At the close of the Journées médicales the Palais des Thermes, at Ostende, was dedicated. The Palais des Thermes is a new institute of physical therapy and seaside treatment, which gives Ostende a medical organization that is unique in Europe. Dr. A. Depoorter, medical director of the institute, gave an address on the work that is to be carried out at the Ostende mineral springs.

Among the more important presentations was "Syphilis in Earlier Times and Today," by Dr. Spilmann. One found formerly a fairly uniform distribution of endemic syphilis in various countries. At present that no longer seems to be the case. Denmark and Belgium have now but little syphilis, whereas France observes no decrease of the disease. Spilmann questions, however, the value of many statistics, which are necessarily incomplete, even in the large cities. It is well known that many practitioners and private institutes do not report their statistics. Furthermore there are many unknown

quantities in this field biotropism, regional influences, racial influences and seasonal influences, which may increase the virulence and aid in the dissemination of the disease

VARIATIONS IN REACTIONS TO SYPHILIS

Dr B Dujardin discussed "The Question of Terrain in Syphilis." It is surprising that the same micro-organism may give rise to such diverse reactions in two different organisms. One never sees two cases of typhoid or two cases of tabes that develop in exactly the same manner. Syphilis has a secondary stage, which decides the later evolution of the infection, or the patient enters an allergic stage that is manifested by a gumma, for example, or it will develop in an anallergic direction, ending finally in dementia paralytica. While the cause of these differences in cases is not known, it is possible to surmise what takes place. Experience has taught that the skin reactions commonly bring relief to conflicts that occur in the deeper tissues (cutaneous reactions to tuberculin, the Schick reaction). Whether it is an unsensitized or a sensitized individual, the reactions of the skin to an antigen vary greatly in different individuals. Some will give no reaction, others will present a severe local or general shock. If one subjects syphilitic patients to these tests, it will be observed that tabetic patients give no reaction (anallergic) but that patients with tertiary symptoms show marked reactions. Between these two extremes there are a multitude of intermediate reactions.

Even in the secondary stage, one may observe this variation in reactions. The syphilitic patient in the secondary stage who is going to become allergic has not always been allergic. In contrast with the syphilitic patient in the secondary stage, a tabetic patient (anallergic) may become sensitized in some peculiar and sudden manner, as by ocular neuritis. Only the female presents leukomelanoderma, which, with its frank adenopathy, requires months to form. Likewise osteitis and osteoarthritis are found more often in females. On the other hand, in anallergic manifestations of syphilis, such as dementia paralytica, one observes ten times as many cases in men as in women. Similar observations have been made with regard to congenital syphilis. Male fetuses are much more susceptible than the female, and stillbirths are much more frequent in males.

This allergy is not, however, specific, either in man or in animals. Allergic persons, when brought in contact with various antigens, give almost parallel reactions. There is, therefore, a polyvalent allergy involved. If all this is true, one can make, on the basis of these intracutaneous reactions, useful therapeutic deductions. If a syphilitic person is anallergic, an attempt should be made to sensitize him, and, if another person is already sensitized, one might be able to increase his allergic capacities. Injection of proteins and malarialization appear to act in this manner. Thus one can see how important is the terrain in the evolution of syphilis, and again, the enormous service that may be rendered by treatment directed toward modification of the terrain.

SYPHILIS IN THE CONGO REGION

Drs Van Den Branden and Dubois presented a paper on "Syphilis in the Congo Region and Its Influence on Tropical Pathology." They called attention to the frequency of syphilis in the Belgian Congo and cited statistics showing that the same is true in many other colonies (Madagascar, French Africa). They described the evolution of syphilis in the natives, the frequency of florid secondary syphilis and of tertiary syphilis resembling closely the tertiary stage of yaws. A few cases of dementia paralytica and of tabes appear to be demonstrated. Opinions are contradictory with regard to the relation between syphilis and trypanosomiasis. In twenty-six cases in which syphilis and trypanosomiasis were diagnosed with certainty, the authors found the same proportion of good results and therapeutic failures as in the group of trypanosomiasis patients that

were not syphilitic. They have reached the tentative conclusion that syphilis does not aggravate trypanosomiasis, but they nevertheless consider it advisable in such cases to administer a combined form of treatment. With regard to the relation of syphilis and malaria, they stated that, while arsphenamines may have a curative effect in malaria due to *Plasmodium vivax*, it appears on the contrary that they may act as a stimulant on *Plasmodium falciparum*. The arsenical treatment of syphilis may therefore be indicated in malaria. Malaria contracted after syphilis would not prevent, by any means, the evolution of neurosyphilis. Syphilis in the Congo region is developing toward neurotropism in spite of the endemic incidence of malaria. Nothing definite is known with regard to the relation of syphilis and recurrent fever.

With reference to the relation between syphilis and yaws, it was stated that in regions in which yaws is widely prevalent syphilis does not progress.

The authors affirmed the independence of syphilis and tropical ulcer, although certain atypical ulcers may possibly develop from syphilis or yaws. The argument based on the action of arsphenamines on tropical ulcer has no value, since the fusospirillary organisms encountered in tropical ulcer are highly sensitive to arsenic.

In spite of the large number of persons in the Belgian Congo found with tattoo markings, the authors did not recall a single case of syphilitic lesions or lesions of yaws developing on keloid cicatrices.

PROPHYLAXIS OF CONGENITAL SYPHILIS

Dr Alexandre Couvelaire of Paris pointed out that the prophylaxis of congenital syphilis dates back many years. Mauriceau, Ambroise Pare and others studied the subject. Their field of action was, however, limited, whereas today prophylaxis might affect the masses, if one so desired. At the Clinique Beaudelocque, the application of prophylactic treatment reduced the fetal mortality, in cases of syphilis acquired during gestation, from 75 per cent to 15 per cent. In cases of syphilis recently acquired at the time of conception, a reduction from 70 per cent to 5.15 per cent was observed, and in cases of syphilis of long standing, although of congenital origin, a decline of from 20 per cent to 7 per cent was noted.

The results of prophylactic endeavors depend on the interest that the public authorities take in the detection centers, the importance of which cannot be too forcibly impressed on the medical profession, notably in connection with prenatal consultations and obstetric services.

THE MODE OF ACTION OF MEDICINES

Dr A. Dustin, in his paper on "Anatomopathologic Side-lights on the Mode of Action of Chemotherapeutic Products," said that the ideas concerning the mode of action of medicine, have changed during recent years. Ehrlich thought that they had a direct sterilizing action on the infective agent, but an objection to his theory was the marked dilution in the organism of the compound introduced, and its rapid elimination. Levaditi and his co-workers, following researches on the action of atoxyl on trypanosomes, think that there is produced a combination of the drug and a protein belonging to the organism itself—a toxiprotein—acting thus directly on the infective agent and also through the defense forces of the organism.

Aschoff introduced into these conceptions of the action of medicines the idea of the reticulo-endothelial system being endowed with peculiar fixation properties toward stains, chemical substances and various particles. The reactions of the lymphoid organs are characterized by the rapidity of their appearance and may be divided into three forms: mitoses, pyknoses and cellular digestion in the macrophages after phagocytosis of the latter, with liberation of their products of disintegration.

These observations serve to explain the part played by the thymus in immunity in relation to the extreme sensitiveness of the thymocytes, the period of latency in the action of chemotherapeutic products necessitated by the ensemble of tissue changes that they cause, the fact that various substances are capable of acting on the same micro-organism, and the important part taken by the injected organism in the mechanism of the action of various therapeutic substances

SYPHILIS AND TRAUMA

Dr Roul Bernard of Brussels presented a paper on "Syphilis in Relation to Trauma." The author considered to what extent syphilis may modify the consequences of a trauma and to what extent the traumatism may influence the evolution and the manifestations of syphilis. There are indisputable cases in which a chancre became grafted on a wound or a case of syphilis inoculated directly through a traumatism. These are exceptional. Cases have been seen in which syphilitic symptoms developed at a spot that had been traumatized. With regard to ocular, visceral and nervous forms of syphilis, traumatic manifestations of the disease are rare and even questionable. Nevertheless, a traumatism may have been the precipitating cause. Trauma may reveal the presence of congenital syphilis, which may retard the consolidation of a fracture. A diagnosis of traumatic syphilis must be reached on careful clinical examination as well as on serologic tests. A test treatment will furnish valuable information. The pathogenesis of such accidents is obscure. One invokes usually mechanical factors such as a circulatory disturbance resulting from traumatism. No doubt the state of sensitization or immunization plays an important part. To prevent the appearance of syphilitic accidents in a traumatized person having a history of syphilis it is necessary to institute energetic treatment extending over a long period. Thus will be prevented what the author calls the avoidable complications" due to lack of care.

Marriages

ARTHUR S. JONES, Huntington, W. Va., to Miss Fanny Harrison Mills of Russellville, Ky., in Louisville, Ky., October 11.

WILLIAM AUGUSTUS ANTHONY, Gastonia, N. C., to Miss Katherine Josephine Williams of Rock Hill, S. C., July 15.

JAMES SHUFORD PALMER, Valdese, N. C., to Miss Lillian Alten Wrigglesworth of Richmond, Va., September 2.

LEWIS HOWARD CAPPETER, Winslow, Wash., to Miss Ruth Allen of Port Blakely in Vancouver, B. C., July 7.

DAVID MITCHELL KEATING, Cleveland Heights, Ohio, to Miss Louise Carew of Youngstown, June 28.

AUSTIN LEWIS KIMBLE, Manoa, Pa., to Miss Eunice May Rousher of Ocean City, N. J., September 7.

NORMAN A. POKORNY, Boston, to Miss Ethel Gladys Kortluke of Richmond Hill, N. Y., July 27.

FRANCIS XAVIER TAMISIA, Missouri Valley, Iowa, to Miss Frances Stessman of Panama, June 5.

JOHN LESH JACOBS, New York, to Miss Marjorie Franks Evans of Brookline, Mass., June 15.

HUGH C. NICKSON, Independence, Mo., to Miss Carolyn Woodward Berridge, recently.

WILLIAM H. S. SPEISSEGGGER, Charleston, S. C., to Miss Laura Agnes Saville, July 18.

WADE THOMAS PARKER, Fayetteville, N. C., to Miss Margaret Frances Blue, in July.

LELAND L. BULL, Seattle, to Miss Alice Horstman of Port Angeles, Wash., July 14.

KENNETH REW, to Miss Catherine McNary, both of Pendleton, Ore., August 4.

CARLYLE ROBERTS PEARSON, Madison, Wis., to Miss Edith Hope Smith, July 8.

Deaths

Joseph Armin Stackhouse, Erie, Pa., Hahnemann Medical College and Hospital of Philadelphia, 1911, member of the Medical Society of the State of Pennsylvania, past president and secretary of the Erie County Medical Society, served during the World War attending physician to the Pennsylvania Soldiers' and Sailors' Home Hospital, aged 43, died, September 4, at his home in Girard.

Samuel Franklin Adams @ White Plains, N. Y., New York Homeopathic Medical College and Flower Hospital, New York, 1920, assistant professor of medicine at his alma mater, member of the American College of Physicians, on the staffs of the Flower Hospital and the Metropolitan Hospital, New York, and St. Agnes' and White Plains hospitals, aged 37, died, September 28, of pneumonia.

Claude Allen Thompson @ Muskogee, Okla., Kansas City (Mo.) Medical College, 1900, member of the House of Delegates of the American Medical Association in 1911 and in 1922 for many years secretary of the Oklahoma State Medical Association, editor of the *Journal of the Oklahoma State Medical Association*, aged 58, died, October 2, of a self-inflicted bullet wound.

John Wix Thomas @ Phoenix, Ariz., Chicago Homeopathic Medical College, 1891, past president of the Maricopa County Medical Society, formerly secretary of the state board of medical examiners, on the staff of the Good Samaritan Hospital, aged 76, died, August 30, in the Good Samaritan Hospital, Los Angeles, of lobar pneumonia.

Frank F. Greene, Olathe, Kan., University of Buffalo (N. Y.) School of Medicine, 1879, member of the Kansas Medical Society, past president and secretary of the Johnson County Medical Society, formerly health officer of Olathe, aged 81, died, September 14, in the Bell Memorial Hospital, Kansas City, Mo., of bronchopneumonia.

Oscar Ofner, Chicago, Hungarian Royal Pázmány Petrus University of Sciences, Medical Faculty, Budapest, Hungary, 1898, member of the Illinois State Medical Society, fellow of the American College of Surgeons, on the staffs of St. Elizabeth's, St. Joseph's and Alex. Brothers hospitals, aged 59, died, October 2, of heart disease.

Joseph Calvert Suter, Grafton, N. D., Trinity Medical College, Toronto, Ont., Canada, 1891, past president of the North Dakota Board of Medical Examiners, fellow of the American College of Surgeons, on the staff of the Grafton Deaconess Hospital, aged 66, died, September 3, of cerebral hemorrhage.

Edgar William Allin, Edmonton, Alta., Canada, Trinity Medical College, Toronto, Ont., 1902, L.R.C.P., London, and M.R.C.S. England, 1903, past president of the Alberta Medical Association, fellow of the American College of Surgeons, on the staff of the Royal Alexandra Hospital, aged 58, died, July 15.

Davis Baker @ Glens Falls, N. Y., Cornell University Medical College, New York, 1909, president of the Warren County Medical Society, fellow of the American College of Surgeons, surgeon to the Glens Falls Hospital and the Emma Lang Stevens Hospital, Granville, aged 48, died, September 28.

Alfred E. Diehl, Buffalo, University of Pennsylvania School of Medicine, Philadelphia, 1892, member of the Medical Society of the State of New York, formerly associate professor of dermatology, University of Buffalo School of Medicine, aged 64, died, September 20, of coronary thrombosis.

Marvin Warren Reed, Denver, Jefferson Medical College of Philadelphia, 1903, member of the Colorado State Medical Society, served during the World War on the staffs of St. Joseph's, St. Anthony's and St. Luke's hospitals, aged 54, was found dead, September 2, of pulmonary hemorrhage.

John Thomas Tucker, Waverly, N. Y., Long Island College Hospital, Brooklyn, 1885, formerly village president and member and president of the board of education, on the staffs of the Tioga General Hospital, Waverly, and the Robert Packer Hospital, Sayre, Pa., aged 73, died, August 20.

Frank Edward Abbett, Indianapolis, Medical College of Indiana, Indianapolis, 1905, member of the Indiana State Medical Association, on the staffs of the Indianapolis City Hospital and the Methodist Episcopal Hospital, aged 52, died, September 17, in a local hospital, of coronary embolus.

Frederick Ellsworth Clark, Burlington, Vt., University of Vermont College of Medicine, Burlington, 1894, formerly associate professor of pathology at his alma mater, served

during the World War, aged 64, died suddenly, September 11, of hemiplegia and coronary thrombosis

Thomas F Willson, Arcola, Miss, University College of Medicine, Richmond, Va, 1899, member of the Mississippi State Medical Association, aged 54, died, September 23, in the King's Daughters' Hospital, Greenville, of hemorrhage due to duodenal ulcer and bronchopneumonia

Harry Leslie Stilphen, Richmond, Maine, University of Vermont College of Medicine, Burlington, 1913 member of the Maine Medical Association, president of the Sagadahoc County Medical Society, aged 50, died, September 9, in the Maine General Hospital, Portland

Benjamin Franklin Iden, Manassas, Va Washington University School of Medicine, Baltimore, 1872, member of the Medical Society of Virginia aged 89, died, September 22, in the Providence Hospital, Washington, D C, of an injury received when kicked by a horse

De Alton Burr Potter, Salisbury, Md University of Maryland School of Medicine, Baltimore, 1904, member of the Medical and Chirurgical Faculty of Maryland aged 54 on the staff of the Peninsula General Hospital, where he died, September 12, of heart disease

William Purkis Watson, Pawtucket R I, Bellevue Hospital Medical College, New York, 1879, member of the Rhode Island Medical Society, for many years on the staff of the Memorial Hospital, aged 81, died, September 12, in Saco, Maine, of heart disease

Pierre Gerold Fermier * Leesburg Ind, Medical College of Indiana, Indianapolis, 1894, county health officer, served during the World War aged 47, died September 19 in the McDonald Hospital, Warsaw, of injuries received when struck by an automobile

Thomas Joseph Francis Murphy, St Jean D'Iberville Que, Canada, Bellevue Hospital Medical College New York, 1888, formerly professor of clinical surgery, Dalhousie University Faculty of Medicine, Halifax, N S, aged 68, died, July 6, in Montreal

Joseph Elmer Schaefer, Cogan Station Pa College of Physicians and Surgeons, Baltimore 1896 member of the Medical Society of the State of Pennsylvania aged 65, died September 17, in the Williamsport (Pa) Hospital, of myelogenous leukemia

Charles Wise Byrd, New York, University College of Medicine, Richmond Va, 1909 member of the Medical Society of the State of New York on the staff of the Manhattan Eye Ear and Throat Hospital, aged 47 died September 14, of heart disease

Marcus T Hickman, Hudson N C University College of Medicine Richmond, Va 1909 member of the Medical Society of the State of North Carolina aged 51, died September 18, in the Caldwell Hospital Lenoir, of a ruptured appendix

Charles C Peck, Harvard Ill Hahnemann Medical College and Hospital, Chicago, 1895 member of the Illinois State Medical Society, formerly county coroner at one time proprietor of a hospital bearing his name aged 62 died, September 17

Robert S Maison, Chester Pa University of Pennsylvania School of Medicine Philadelphia 1890 member of the Medical Society of the State of Pennsylvania aged 66 died August 31, in Manassas N J of chronic myocarditis and nephritis

Joseph Charles Edward Daunais, Ste Anne des Plaines, Que Canada School of Medicine and Surgery of Montreal Faculty of Medicine of the University of Laval at Montreal, 1891 aged 66 died May 1 of hepatic and renal insufficiency

Ray Morrison Means, Shively Ky University of Louisville School of Medicine 1904 served during the World War, aged 51 on the staff of the SS Mary and Elizabeth Hospital where he died September 18 of myelogenous leukemia

Charles Sumner Knight, Falmouth Heights Mass University of Michigan Medical School Ann Arbor 1878 member of the Massachusetts Medical Society aged 77 died September 21 at Westboro of cerebral hemorrhage

Frank L Kinsey, Fremont Ohio Medical College of Ohio Cincinnati 1882 member of the Ohio State Medical Association aged 72 died September 8 in the Memorial Hospital following an operation for appendicitis

Isaac Bowden * Port Huron Mich Detroit College of Medicine 1904 served during the World War aged 55 on the staff of the Port Huron Hospital where he died September 19 of carcinoma of the prostate

John Roberts Green, Nashville, Tenn, University of Tennessee Medical Department, 1904 member of the Tennessee State Medical Association, aged 60, died, September 3, in a local hospital of strangulated hernia

Claude Raymond Matthis, Amity, Ore, Memphis (Tenn) Hospital Medical College, 1894, past president of the Oregon Board of Medical Examiners, aged 64, died, August 2, following an operation for mastoiditis

Addison Kendall * Great Bend, Kan, Hering Medical College, Chicago 1901, formerly member of the state board of medical registration and examination and state board of health, aged 68, died, August 29

Charles Martelle Coker, Eden, Miss Memphis (Tenn) Hospital Medical College, 1896, aged 65, died September 20, in a hospital at Vicksburg, of pernicious anemia, hypertrophy of the prostate and phlebitis

Robert Lee Marchant, Greer S C, Kentucky School of Medicine, Louisville, 1889 member of the South Carolina Medical Association, aged 67, died, September 8, of acute dilatation of the heart

John Stephen Malone, Poughkeepsie, N Y, Syracuse University College of Medicine, 1919, formerly on the staff of the Vassar Brothers Hospital, aged 38, died, September 22, of heart disease

Thornton Kirkland Perry, Albany, N Y, Albany Medical College, 1875, aged 81, died, September 5, in the Hudson River State Hospital, Poughkeepsie, of arteriosclerosis and chronic myocarditis

Isaac Barber, Philipsburg, N J University of Pennsylvania School of Medicine, Philadelphia, 1879 formerly city physician and health officer, aged 79, died, September 30, of arterial hypertension

Chalmer Roswell Hecox, Golden Ill, College of Physicians and Surgeons Keokuk, Iowa 1897 member of the Illinois State Medical Society, aged 58, died suddenly, September 8, of heart disease

Harry Nathaniel Mayo, Los Angeles Baltimore Medical College, 1895, fellow of the American College of Surgeons, served during the World War, aged 65, died, September 7, of arteriosclerosis

William E Holmes, Brownsville Ohio, Medical College of Ohio, Cincinnati, 1884, aged 77 died September 10 in the City Hospital, Newark, of paralysis agitans and hypertrophy of the prostate

T W Williams, Litchfield Ill American Medical College, St Louis 1879, aged 78, died suddenly, August 31, in St Luke's Hospital, Davenport, Iowa, of hemorrhage due to duodenal ulcer

Tina Gardiner Head Patrick, Vancouver B C Canada Trinity Medical College Toronto, Ont, 1896, aged 71 died May 17 in the General Hospital, of a fractured hip received in a fall

John Marius Challen Cook, Weston, Ohio, Long Island College Hospital, Brooklyn, 1887 for many years member of the board of education, aged 74, died, September 10, of heart disease

Ava Hamlin Fenn, Meriden, Conn College of Physicians and Surgeons, Baltimore, 1886, member of the Connecticut State Medical Society, aged 86, died, September 15, of heart disease

Owen Riley Marshall, Moody, Texas, Vanderbilt University School of Medicine Nashville Tenn 1899, served during the World War aged 61, died September 9, of heart disease

Robert Edwin Wilson, Davidson Okla Southwestern University Medical College Dallas, Texas 1904 aged 62, died July 24 in Wichita Falls Texas, of pneumonia

Laurence Bailly Powell, Moorestown N J Hahnemann Medical College and Hospital of Philadelphia 1931 aged 26 died September 18 of a self inflicted bullet wound

James Drew Ingram, McBee S C Atlanta College of Physicians and Surgeons 1902 aged 55 died September 15, in the McLeod Infirmary, Florence of pneumonia

Albert Edwards Wilson * Norfolk Va University of Maryland School of Medicine Baltimore, 1896 aged 65, died in September of benign prostatic hypertrophy

Seth Harold Jones, Holt, Mich University of Michigan Homeopathic Medical School Ann Arbor 1906 aged 53 died September 5 of abdominal metastatic sarcoma

Anderson P Jones * Pennsboro, W Va (licensed West Virginia by years of practice) county health officer, aged 80 died, September 9 of coronary embolism

Joseph Odilon Drouin, Grande Baie, Que., Canada Laval University Faculty of Medicine, Quebec, 1900, aged 57, died suddenly, July 29, of cerebral hemorrhage

Francis H. Geer, Claremont, Calif., Medical College of Ohio, Cincinnati, 1877, aged 84, died, July 20, in Pomona, of arteriosclerosis and cerebral hemorrhage

Michael Arthur Mellenstien, Los Angeles, Medical Department of Hamline University, Minneapolis, 1906, aged 50, died, September 24, of heart disease

David C. McKenzie, Granville, N. Y., University of Maryland School of Medicine, Baltimore, 1891, aged 67, died, September 17, of pulmonary tuberculosis

Joseph Ditman Lawrence, Sprigg, W. Va., Hahnemann Medical College and Hospital of Philadelphia, 1893, aged 62, died, August 25, of angina pectoris

Walter Denison Leach, Detroit Lakes, Minn. College of Physicians and Surgeons of Chicago, 1895, aged 76, died suddenly, September 4, of heart disease

Edward Joseph Donlin, New York University of the City of New York Medical Department, 1876, aged 81, died, September 23, of bronchopneumonia

Louis E. Eddy, Port Clinton, Ohio, Louisville (Ky.) Medical College, 1893, aged 72, died, September 28, in the Pool Hospital, of cardiac asthma

Eugene Derome dit Descarreau, St. Augustin de Quebec, Que., Canada Laval University Faculty of Medicine, Quebec, 1901, aged 58, died, August 8

Lurana Abbie Chubbuck, New Bedford, Mass., Boston University School of Medicine, 1894, aged 76, died, September 1, of coronary thrombosis

William C. Lewis, Jersey City, N. J., University of Pennsylvania School of Medicine, Philadelphia, 1880, aged 75, died, September 12, of cholelithiasis

James Lee Bell, Malone, Fla. Georgia College of Eclectic Medicine and Surgery, Atlanta, 1909, aged 52, died, September 8, of cerebral hemorrhage

Paul Trudel, Ste. Genevieve De Batiscan, Que., Canada, School of Medicine and Surgery of Montreal, 1896, aged 59, died, June 19, of carcinoma

Andrew Johnson Isham, Maryville, Tenn. University of the South Medical Department, Sewanee, 1900, aged 70, died, September 1, of pneumonia

Ira E. C. W. Smith, Palmetto, Ga., Atlanta College of Physicians and Surgeons, 1905, aged 50, died, September 4, in Newnan of pneumonia

Clarence Niles Payne, Fairfield, Conn. New York Homeopathic Medical College, 1885, aged 71, died, September 8, of carcinoma of the stomach

Haude T. Dacus, Williamston, S. C., Baltimore Medical College, 1902, aged 54, died, September 13, in the Greenville (S. C.) City Hospital

William Bay Stoker, Ottumwa, Iowa College of Physicians and Surgeons, Keokuk, 1896, aged 65, died, September 6, of pernicious anemia

Vincent Z. Keeler, Harleysville, Pa., Jefferson Medical College of Philadelphia, 1880, aged 75, died, September 11, of heart disease

Fred McCandless, Ludington, Mich., Chicago Homeopathic Medical College, 1894, aged 64, died, September 11, of locomotor ataxia

Reuben Hugh Hannah, Prague, Okla., Gate City Medical College, Dallas, Texas, 1906, aged 75, died, July 17, of heart disease

Peter L. Coble, Celestine, Ind. (licensed, Indiana 1897) formerly state senator, aged 80, died, September 14, of heart disease

Peter Goosen, Enid, Okla. American Medical College, St. Louis 1891, aged 78, died, August 30, of cerebral hemorrhage

Henry C. Iseman, Beaver Falls, Pa. (licensed, Pennsylvania, 1885) aged 101, died, September 5, in Ithaca, Mich.

George Cameron McGibbon, Honeywood, Ont., Canada Trinity Medical College, Toronto, 1899, aged 62, died, July 28

Joseph Addison Sweeney, Louisville, Ky., Hospital College of Medicine, Louisville 1902, aged 59, died, July 17

Earl Kinton Wheelis, Blanton, Ala., Atlanta College of Physicians and Surgeons, 1911, aged 44, died, July 13

R. Carson Stone, Russellville, Tenn. (licensed, Tennessee, 1889), aged 72, died, September 12, at Clinton

Correspondence

PSEUDO-AGGLUTINATION IN BLOOD

To the Editor—In *THE JOURNAL* August 19, page 627, a correspondent writes concerning the difficulties he is encountering when determining the blood groups of pregnant and anemic patients. In your reply you point out that the blood group of an individual remains constant throughout life and is unaffected by disease or pregnancy. However, there are other phenomena that have been mistaken for true isoagglutination, and one of these (rouleau formation) is particularly pronounced in pregnant women.

Rouleau formation is a phenomenon occurring in normal individuals (but only to a mild degree), which is characterized by a piling up of the blood cells, resembling piles of coins. In conditions associated with a rapid sedimentation time, this phenomenon is much more marked. In pregnancy and severe anemias rouleau formation may be so pronounced that the clumps become large and irregular, resembling superficially the clumping caused by true isoagglutination. Such pronounced rouleau formation is therefore known as "pseudoagglutination." Pseudoagglutination can most readily be recognized by examination of the specimen under the high power of the microscope and by the fact that the clumps disappear on slight dilution. (Other criteria for differentiating true isoagglutination and pseudoagglutination are given by Landsteiner in *Jordan and Falk's Newer Knowledge of Bacteriology and Immunology*, 1928, p. 899, and by A. T. Coca, *Note Concerning Differences Between the Clumping of Pseudo-Agglutination and Iso-Agglutination*, *J. Immunol.* 20:263 [April] 1931.) The simplest way to prevent pseudoagglutination is by making the tests with dilute suspensions of the patient's blood (from 1 to 5 per cent). The reason for this is that the active principle responsible for pseudoagglutination is present in the serum. The most certain way of preventing pseudoagglutination is by using washed cells, thus entirely removing the troublesome serum.

ALEXANDER S. WIENER, M.D., Brooklyn

CONTROL OF TYPHOID CARRIERS

To the Editor—As a former health officer I read with great interest the paper by Bigelow and Anderson on the cure of typhoid carriers, in *THE JOURNAL*, July 29. My interest was aroused at the remark "our inability to make certain that the stool specimen submitted actually came from the carrier," as nearly thirty years ago, in a case in which I rightly suspected that I was deceived as to the origin of the stool specimens, I employed a method of control without hospitalizing the suspected carrier, that might be of use also in American health offices.

Before recommending it I may tell a curious event, which illustrates the necessity of always being suspicious. A farmer's wife living in a hamlet in Westphalia was under observation as a typhoid carrier. The specimens of her stool varied from positive to negative. Once when she was told that the last specimen had been found positive she came to the office of the medical officer protesting. You can see that the examinations of your laboratory are not reliable. The last specimen that I handed to the health surveyor was not stool of mine but of my friend Mrs. Z'. Notwithstanding the fact that this woman resided in another hamlet beyond the border of the county, it was managed to procure an authentic stool specimen from her, with the result that one more typhoid carrier was listed.

The procedure adopted by me is the following. The nurse or disinfecter collecting the specimens makes the suspected carrier swallow in his presence a capsule or wafer of an equal

mixture of lycopodium, powdered animal charcoal and sodium sulphate or another mild laxative and instructs him to collect the stool of the next morning. In the laboratory, besides the cultivation of bacteria, the lycopodium spores are looked for with the microscope in the black parts of the stool in the same manner as eggs of helminths. I was led to adopt the procedure by the remark in a textbook that, in seeking the eggs of helminths, one must not be deceived by finding the curious and characteristic spores of lycopodium, as it is customary to powder pills with lycopodium.

I do not offer this procedure as a substitute for the method of Bigelow and Anderson, who recommend bile cultures by the duodenal tube before and after an operation on a carrier, but in the first year, before a carrier is finally listed, and in the control of carriers and suspected persons who decline to be hospitalized, it should be of value in ascertaining the true origin of the specimens.

WERNER ROSENTHAL, M.D., Magdeburg, Germany

USE OF SODIUM AMYTAL IN STRYCHNINE POISONING

To the Editor—In a recent edition of THE JOURNAL I read with interest an article regarding the intravenous use of sodium amytal in the treatment of strychnine poisoning. In the past week I have had the opportunity to put this new treatment into practice with favorable results. I was called to see a man, aged 33, who had taken what I estimated to be 15 grains (1 Gm) of strychnine sulphate crystals about two hours before my arrival. I base my estimate as to the amount on the fact that the bottle containing the remaining strychnine was one-half empty, the full bottle having contained one-sixteenth ounce, and according to the man's wife, who was present, he had consumed this amount. The patient when first seen was lying quiet but in a few seconds a typical strychnine spasm manifested itself. The position was that of opisthotonus, the spasm lasting for about one and one-half minutes. The typical sensation of approaching death (as described by Beckman) was present between this and the preceding spasm, and manifested itself in about five minutes. Two glasses of mustard water were administered as an emetic immediately with no resulting emesis. It may be of interest to note that the patient in attempting to bring about emesis by means of gagging himself with his finger was quite severely bitten, owing to the sudden contraction of the muscles acting on the mandible.

The patient was given 6 grains (0.4 Gm) of sodium amytal orally and taken to the hospital. There the spasms were even more severe and gastric lavage was instituted. Owing to the severe contractions of the mandible, a nasal tube was used in the lavage, the oral route not being practical.

After the large, $1\frac{1}{2}$ ounces (45 Gm) of magnesium sulphate was instilled into the stomach. Following the lavage and instillation, 5 grains (0.3 Gm) of sodium amytal was given intravenously, with resulting emesis followed by a deep sleep and complete relaxation. The patient was put to bed and slept soundly for about half an hour, awakening at this time in a state of restlessness and moderate excitement, no doubt a manifestation of the sodium amytal. No more spasms were noted but the restlessness continued and about two hours following the administration of the sodium amytal 30 grains (2 Gm) of chloral hydrate was given by means of a retention enema. The patient slept for the remainder of the day and was not disturbed aside from the administration of a soap suds enema late in the day. The following day he was much stronger but was kept quiet by the use of sodium amytal orally, approximately 12 grain (0.8 Gm) being required. On the third hospital day the sodium amytal was discontinued and the patient allowed

to rouse. There was some excitement and restlessness, but he ate well and showed no residual symptoms of the poisoning aside from a retention of urine, this no doubt resulting from contraction of the vesical sphincter. The patient was catheterized at two intervals and the following day was able to void. Further recovery from the strychnine poisoning was uneventful.

BRIAN C. FENTON, M.D., Lincoln, Neb.

A DEATH FROM ALPHA-DINITROPHENOL POISONING

To the Editor—At 6 25 p.m., August 27, H. G. was admitted to the Central Emergency Hospital with the complaint that he had taken 5 grains (0.3 Gm) of alpha-dinitrophenol that morning at 11 50. The patient stated that he was an M.D., a graduate of Vienna, and that he had taken a dose one week before (August 20) without untoward results.

The patient informed Dr. Charles Bennenger, the assistant surgeon, that he had obtained the drug from a physician at a local hospital in order to attempt a reduction in his weight.

Soon after taking the drug at 11 50 a.m., the patient stated that he went for a walk and returned to his rooms soon afterward. About 4 p.m. he began to notice a feeling of apprehension, other than palpitation, he had no definite complaint. He became more restless and uneasy, and finally, about 6 o'clock, requested his hotel to telephone for an ambulance.

On admission he appeared pale, agitated and markedly apprehensive. Physical examination was negative. He was placed in bed, where he complained of being warm and persisted in throwing off the covers. He requested that more windows be opened or that he be taken on the roof for more air. He also complained of severe pain and stated that there was considerable air hunger, without actual dyspnea. Restlessness and apprehension increased, and there was a progressive rise of temperature, with frequency pulse rate and respiration. There was profuse perspiration, the temperature rose to 105.4 F. The pulse on admission had been 84 and increased until 9 30, when it registered 146 beats per minute. The patient lapsed into delirium and coma at 9 45 and died at 10 o'clock. The rectal temperature was taken at this time, and the mercury column registered at the top of the thermometer (110 plus). Within twenty minutes his body was in boardlike heat rigor. The amount of the drug taken was estimated post mortem by an expert at 25 to 5 Gm., which is fifteen times the ordinary dosage.

J. C. GLIGER, M.D., San Francisco

A LARGE GALLSTONE

To the Editor—I removed a gallstone from a woman yesterday which I think is the largest individual gallstone in the country. If there is a larger one please let me know. The stone weight and measurements are weight $2\frac{1}{2}$ ounces (70 Gm), length, 3 inches (7.5 cm), diameter, $1\frac{1}{8}$ inches (4 cm), circumference, $4\frac{1}{2}$ inches (11.5 cm). It was greenish gray and firm and was the only stone in the bladder. The size of the gallbladder was $8\frac{1}{2}$ inches (21.5 cm), diameter, 2 inches (5 cm).

FRED G. BUSHOLD, M.D., Lawrence, Mass.

COMMENT—Sternberg reported in Aschoff's "Pathologic Anatomy," edition 6 a gallstone 14 cm across and weighing 200 grams, or 13 Gm. Rankin and McKeith reported a gallstone measuring 69 by 85 cm. Clement found one measuring $2\frac{1}{2}$ by $1\frac{1}{4}$ inches or 63 by 31 cm. Bennett removed one at operation with a circumference of $5\frac{1}{2}$ inches (14 cm) and weighing 636 grams (413 Gm). A case was reported in THE JOURNAL by A. L. Russell July 27 1901, page 265. The gallstone in that case measured $5\frac{1}{4}$ by $4\frac{1}{2}$ inches (14.5 by 11.4 cm).

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

CHRONIC NEPHRITIS

To the Editor—The following case has proved a puzzle to me as to both classification and etiology. A white woman aged 20 single American first requested advice because of puffiness of the hands and feet, scanty urination and weight gain of 36 pounds (16 kg) in two months drowsiness and inability to concentrate on her duties as a book keeper. The past history is negative except for a gastro-enterostomy performed two years before for peptic ulcer. Convalescence was uneventful and at present the patient is comfortable on a bland diet. Urine examination at the time of operation was negative throughout. The history of the organ systems and the menstrual history are all negative with the exception of a marked constipation dating back to the time of the surgical procedure and for which the patient takes from four to eight compound cathartic pills each night. Physical examination is negative except for pitting edema of the hands the feet and the legs to the knees. There is moderate pallor. The blood pressure is 135 systolic 90 diastolic. The weight is 149 pounds (67.6 kg). Hemoglobin is 40 per cent. The red blood cells number 4 500 000. Examination of the urine reveals specific gravity, 1.030 albumin negative sugar negative white blood cells negative red blood cells negative hyaline casts + + granular casts + benzidine test negative. The patient refused a blood chemistry examination. On repeated examinations of the urine no trace of albumin has ever been found by any of the standard tests. Casts are constantly present. The edema has been readily controlled by the use of ammonium chloride and a profuse diuresis has followed the use of salyrgan. The weight has been maintained at from 130 to 135 pounds (59 to 61 kg) and the anemia has improved with copper and iron. All of the original complaints and signs reappear as soon as the patient is taken off the diuretics. Specifically what type of nephritis am I dealing with in the absence of albumin and the presence of hyaline and granular casts? Could the constant dosage with compound cathartic pills be an etiologic factor? What is the prognosis? What treatment is indicated? My available literature has furnished no light on these difficulties. Please omit name. M D Ohio

ANSWER—Accepting the statement that there is no disturbance in the heart or the liver to account for the edema, the case is apparently one of chronic nephritis, but the laboratory data, as given, are not sufficient for a complete diagnosis. The edema seems too extensive to be of nutritional origin. The exhaustion, oliguria, edema, moderate elevation of blood pressure (the normal pressure for a woman of 20 is about 110 to 120 systolic about 80 diastolic) and cylindruria suggest chronic glomerular or diffuse nephritis. However, in chronic glomerular nephritis one would expect to see a definite reduction in erythrocytes as well as hemoglobin, and one would not ordinarily expect to find a urinary specific gravity of 1.030. Cases of chronic glomerular nephritis without albuminuria have been recorded but are certainly the exception, patients with chronic glomerular nephritis generally demonstrate on repeated examinations at least slight albuminuria. Albuminuria is expected even more in chronic nephrosis or tubular nephritis. In the absence of erythrocytes, pus cells or a history of renal colic tuberculous or calculous renal disease or pyelonephritis seems unlikely. When polycystic kidneys are present, at least one kidney is generally found to be enlarged. In the various toxic nephroses, albuminuria with or without edema is present. A generalized edema occurring only at the menstrual period, associated with headaches, choked disks and anuria, and in one case completely relieved by injection of the active hormone of the anterior pituitary gland has recently been described (Thomas W A Generalized Edema Occurring Only at Menstrual Period, *abstr THE JOURNAL*, January 7, p 68).

The discrepancy between the low value for hemoglobin and the relatively normal erythrocyte count needs further investigation, and a chemical analysis of blood, preferably its urea content, should be insisted on for adequate diagnosis and treatment. If this is refused, the excretion of phenolsulphonphthalein should be studied. A clinically accurate approximation of nitrogen concentration can be obtained by the determination of the salivary urea index (Hench, P S, and Aldrich Martha A Salivary Index to Renal Function *THE JOURNAL* Dec 15 1923 p 1997). The water and concentration tests also should be done.

If evidence of retention of nitrogen is found a diet containing about 50 Gm of protein should be given, no extra salt being allowed. If the nitrogen retention is marked intake of fluid should not be restricted below 1000 cc in spite of the edema. The use of ammonium chloride might decrease the alkali reserve and ammonium chloride or ammonium nitrate might increase the retention of nitrogen. Administration of potassium nitrate (from 6 to 8 Gm daily) would be preferable and might control

the edema without the use of salyrgan, which should be used cautiously if at all when retention of nitrogen or hematuria is present. The patient's physical activities should be minimal rest in bed probably being desirable to minimize the catabolism of nitrogen. Exposure to cold and fatigue should be avoided. Removal of foci of infection may be important. If there is no retention of nitrogen, restriction of protein is not required indeed may be contraindicated, but restriction of salt and water are indicated.

No definite statement regarding prognosis can be made until the patient has been observed from six to twelve months. If then there is no evidence of progressive renal insufficiency, increase in hypertension alteration in cardiac size and function, or changes in the ocular fundi, the diagnosis of quiescent renal lesion may be justified and a good prognosis given.

It is not likely that the use of compound cathartic tablets is responsible for the condition. These tablets are generally supposed to contain extract of colocynth calomel resin of jalap and gamboge powder. However transient renal irritability with albuminuria, on rare occasions has been ascribed to phenolphthalein used as a laxative (Effects of Phenolphthalein on Kidney *THE JOURNAL*, August 5, p 469).

LEUKORRHEAL DISCHARGE AFTER COITUS

To the Editor—A married woman aged 22 who has been menstruating regularly complains of a leukorrhea lasting from twenty four to forty eight hours following coitus and also each menstruation. There is no leukorrhea then until after the next coitus. The patient has never been pregnant and she has noticed the symptoms since marriage. Vaginal and bimanual examinations reveal no pathologic changes. There is no history of acute gonorrhea in the woman or her husband but the husband developed an acute prostatitis a few weeks following a severe attack of scarlet fever about one year ago. I should like to know whether the leukorrhea is physiologic or indicates a pathologic condition. Please omit name. M D Pennsylvania

ANSWER—A leukorrheal discharge for a few days after the menstrual flow is not uncommon and requires no treatment except when it is due to endocervicitis trichomonas vaginitis or moniliasis. The leukorrhea that follows intercourse in this case is most likely not pathologic. It may be the result of the technique of coitus employed by the couple. For example if the coital act is long drawn out before the orgasm is experienced there is opportunity for marked congestion in the pelvic organs and for a profuse vaginal discharge. This may persist for a day or two after intercourse. Likewise if the woman is aroused sexually and does not have an orgasm because the husband has his orgasm prematurely and discontinues the act a leukorrheal discharge may follow such an occurrence. If the woman is repeatedly aroused and regularly frustrated in her desire to have an orgasm, a leukorrheal discharge may be permanently present. In such cases treatment must be directed at the cause. Local treatment will do no good and may result in harm. A moderately warm tap water douche shortly after intercourse may prove helpful. However, if the discharge is not annoying and the husband and wife are satisfied, no treatment need be instituted.

LOWER ABDOMINAL ANESTHESIA

To the Editor—What is the exact technique of Truog's method of lower abdominal anesthesia (*Monatsschr f Geburtsh u Gynak* 90 1933 [Jan] 1932)? I don't trust my translating ability. What is your attitude toward the method? Is there a spinal anesthetic on the market that does not depend for its localization on the position of the patient? Somewhere in my reading I have run across some sort of acecia mixture especially adaptable to beginners in spinal anesthesia. Is there such a product and is it on the market?

ROBERT MO FORT M D Wolverine, Mich

ANSWER—The method consists of a paravertebral injection of 30 cc of 0.5 per cent procaine hydrochloride at the height of the third lumbar vertebra. The patient sits on the edge of the table with a curved back. The third lumbar spinous process is located. A dermal wheal is produced four fingerbreadths to the right and left of the spinous process and a 12 cm needle is inserted in the horizontal plane but at 45 degrees toward the midline. After the transverse process is reached the needle slips past the bony resistance and arrives at the lateral surface of the third lumbar vertebra. At this point, after aspiration for blood, an ounce of procaine is deposited on both sides.

The patient is then laid on her back and the abdominal wall is infiltrated layer by layer. The rectus fasci is injected after the incision through the skin and the subcutaneous fat has been made. After the peritoneum is opened and the intestines are gently packed away from 3 to 5 cc of 0.5 per cent procaine is injected into the round ligament and the ovarian or infundibulopelvic ligaments according to the operation planned. Finally from 20 to 30 cc of the anesthetic solution

is deposited between the two layers of the broad ligament into the parametrium. Now the uterus may be grasped and pulled forward. If there is still some sensation of pain on traction, the sacro-uterine ligament may be injected.

The patients are prepared with scopolamine (1/200 grain, or 0.0003 Gm.) and morphine (1/4 grain, or 0.016 Gm.) two hours and one hour before the operation, or a barbituric sedative is administered.

In approximately 10 per cent of the ninety-one laparotomies a short nitrous oxide anesthesia was added. For vaginal hysterectomies the paravertebral anesthesia is supplemented with a parasacral block or parametrium injections on both sides of the uterus.

It can be readily seen from this description that the method requires considerable skill and experience in various forms of local anesthesia. Professor Frigyesi, who has perfected this combined form of anesthesia during the last fifteen years, is the head of a large gynecologic and obstetric service and has a large group of trained assistants. Under such ideal conditions this lower abdominal anesthesia is feasible and successful, although there were partial failures which had to be supplemented with nitrous oxide in 10 per cent of the cases. For the casual surgeon the method is too complicated and cumbersome. Paravertebral anesthesia is not without danger in the hands of men without special training in this method.

In regard to spinal anesthesia, the surgeon should be thoroughly familiar not only with the technic but also with the physiologic effects, the dangers and the limitations of this method. The monograph of Charles H. Evans (New York, Paul B. Hoeber, 1929) is recommended for study. There is no such thing as spinal anesthesia for beginners. Spinal anesthesia is a valuable method if used with discrimination. Dissolving the procaine crystals in the patient's own spinal fluid seems to be the most desirable procedure. The height of the anesthesia can be governed by various dilutions of the anesthetic and by air insufflation.

RELATION OF PARATHYROID GLANDS TO FORMATION OF RENAL STONE

To the Editor—A patient has passed a number of stones from both kidneys most of these with the usual symptoms of renal colic but on three different occasions a urinary retention with a severe pyelitis has supervened that necessitated major surgery. He has been advised to have roentgen therapy to the parathyroid glands with the idea of diminishing the blood calcium. His calcium content varies from 9 to 10.5 mg. Is there a definite relation between the formation of renal calculi and calcium content in the blood? 2. Would roentgen therapy to the parathyroid gland control the blood calcium? 3. Would such therapy prevent further formation of stones? Please omit name.

M D Illinois

ANSWER—1. We are not aware of any relation of the sort indicated. From the analyses of Kahn and Rosenblum (THE JOURNAL, Dec 21, 1912, p. 2252) and others it would appear that the majority of renal stones are composed mainly of calcium oxalate or phosphate or a mixture of the two. There is evidence associating formation of bladder calculi composed of calcium phosphate with a deficiency of vitamin A. Whether the association is direct, or some other dietary deficiency is involved, is perhaps not satisfactorily settled. The references are Osborne and Mendel (THE JOURNAL, July 7, 1917, p. 32); McCarrison (Brit. M. J. 1, 717 [April 16] 1927); Fujimaki (Japan M. World 6, 29 [Feb.] 1926, abstr. Chemical Abstracts 20, 2694 [Aug. 20] 1926 and THE JOURNAL, June 19, 1926, p. 1946); van Leersum (J. Biol. Chem. 76, 137 [Jan.] 1928).

Of forty-five cases of parathyroidism analyzed with relationship to renal calculi, heavy calcium deposit in the urine and milky urine were mentioned twice, fine gravel once and bilateral renal calculi were present seven times. Of Donald Hunter's four classic cases of parathyroid tumors renal calculi were found in three. These figures are in fact higher if the symptom is more often sought. In parathyroidism under the influence of an increased output of parathyroid from the irritated little glands, calcium is liberated from the bones in excess. Hypercalcemia follows and this again leads to secondary calcium deposits in the internal organs, ligaments and so on especially in the kidneys. In this way the foundation for renal calculi in hyperparathyroidism is laid. Old cases of parathyroidism therefore are frequently accompanied by stones and secondary pyelitis. A few patients have died even after successful operations for parathyroid tumor from such secondary changes in the kidney. Therefore this is one of the reasons why early operation is indicated in the diagnosis of parathyroid tumor is made.

2. To be sure, in a given case it has to be established whether the patient with symptoms of nephrolithiasis has other symptoms of parathyroidism such as changes in the skeleton, high

serum calcium, increased calcium output in the urine, and hypotonia. If such symptoms are present, parathyroid origin of the kidney stones may be thought of, otherwise, kidney stones may well arise from other causes, such as focal infections.

3. If the diagnosis of parathyroidism is established as a possible cause of the renal disturbance, parathyroidectomy or roentgen treatment of the parathyroid region may be considered. So far the roentgen therapy of parathyroid tumors and hyperplasias has only exceptionally been mentioned as successful. Parathyroidectomy in a well established case is generally preferred to roentgen therapy. The removal of a parathyroid tumor (adenoma or hyperplasia) might prevent further formation of stones. To be sure, the harm done (secondary infections, hydronephrosis and pyonephrosis) needs special attention besides the treatment directed toward the parathyroids.

COSMETIC TREATMENT OF WRINKLES ON FACE

To the Editor—I have a female patient aged 40 whose face is prematurely wrinkled. She has spoken to me regarding a peeling treatment as used in beauty parlors. What are the usual solutions used and what procedure is followed? What can be done with ultraviolet radiation in producing exfoliation in these cases? Kindly omit name.

M D New York

ANSWER—Wrinkling is caused by loss of elasticity of the skin through degeneration of its fibers. No treatment can cure it or restore to the skin its youthful elasticity and smoothness. Slight inflammation causes swelling and temporarily smooths out the wrinkles but with its subsidence they return. Such an inflammation followed by exfoliation, can be caused by ultraviolet radiation by freezing with carbon dioxide snow or by chemical irritants. Of the latter the simplest is a solution of corrosive mercuric chloride in alcohol, 1 per cent, painted on a small area daily and allowed to dry on. After a few to several days of this treatment the skin becomes red when the treatment is stopped and exfoliation awaited. Or the peeling paste used for acne may be used.

	Gm. or Cc.
Betanaphthol	10
Precipitated sulphur	40
Soft soap U. S. P.	25
Petrolatum	25

If this turns dark it does not indicate any loss of activity. It must not be used in cases in which the kidneys are impaired, and during its use the urine must be watched for signs of kidney irritation. Like the preceding, it must be used on small areas only and not given to the patient to apply, but she must come daily to the doctor for the application.

The area should be washed with ether or benzine and the paste should be spread thickly and allowed to remain for twenty to thirty minutes when it is removed thoroughly. Soon after application a slight burning sensation is felt, but this ceases in a few minutes. After the removal of the paste, the skin is red for a few hours. The treatment should be repeated each day until a tightening sensation or the onset of exfoliation shows that treatment has been sufficient. Five days is usually enough. During treatment no soap or water is to be used on the areas treated but they may be cleansed by 0.5 per cent salicylic acid in alcohol.

Perhaps the beneficial effect may last as long as the time consumed in treatment. Any such inflammation may result in increase of pigmentation. Overtreatment may be distressing. We strongly advise against the attempt to improve wrinkles in this way.

BLOOD SEDIMENTATION TESTS

To the Editor—Will you please supply me with data relative to blood sedimentation test as done with a 5 cc. tube giving technic, interpretation, averages and relative rate that is rapid, moderately rapid and extremely rapid. Also the relation to polymorphonuclear count and to filament count. Please omit name.

M D Wisconsin

ANSWER—The blood sedimentation test referred to is the graphic method of Cutter. A special sedimentation tube of 5 cc. capacity is used which is graduated in tenths of a centimeter, each 1 mm. in height and marked in millimeters. Tubes answering these specifications may be obtained from the A. H. Thomas Company of Philadelphia. In this method the position of the sedimenting column of red cells is recorded every five minutes for one hour. The test is performed as follows: Five cc. of venous blood is aspirated into a carefully cleaned syringe containing 0.5 cc. of freshly prepared 3 per cent sodium citrate solution. When the blood is drawn the barrel of the syringe is drawn backward about 1 cm. and the syringe is gently tilted backward and forward several times to insure uniform mixing of the blood and citrate solution. (If clotting occurs the test must be repeated.) The needle is removed

from the syringe and the contents are poured into the sedimentation tube. The tube is stoppered with a paraffin coated cork and inverted two or three times. The tube is placed in a rack and the position of the column of red blood cells is recorded every five minutes for one hour as it settles down. The observations are recorded on a sedimentation chart on which the horizontal lines represent the divisions of the sedimentation tube and the vertical lines the intervals of time. Printed forms may be obtained from Charles M. Berkemeyer, Sellersville, Pa. The graph serves as a rough estimation of the presence or absence of pathologic activity. The sedimentation index is the total sedimentation of red blood cells at the end of sixty minutes expressed in millimeters. The normal averages vary for men from 3 to 4 mm and for women from 5 to 6 mm. During menstruation it may be as high as 12 mm. It is normally increased in the new-born and the aged. The significant changes occur in the first thirty minutes. In the presence of severe acute inflammation the rate may be extremely rapid and reach from 25 to 30 mm the first thirty minutes, producing what Cutler has termed a vertical curve on the graph.

The mechanism whereby changes occur in the polymorpho-nuclear and filament count and the sedimentation rate are different. The two examinations supplement each other. The leukocyte count is influenced not only by the disease process but also by the patient's ability to react. A change in the leukocyte count appears before the sedimentation is significantly influenced. The sedimentation rate expresses a condition in the body and not a reaction of the body. For example, in severe infections both tests show marked changes. Weeks later the leukocyte count may fall to normal while the sedimentation index will remain high in spite of an obvious clinical improvement. The sedimentation rate indicates more delicately the complete healing of a diseased tissue than does the study of leukocytes. Because of other factors influencing the sedimentation rate, however, conclusions on this test alone are often misleading.

FEVER OF UNKNOWN ORIGIN IN CHILDHOOD

To the Editor—A child now 2½ years old was first seen when 8½ months old. He was brought because of a constantly elevated temperature which had been present for about seven weeks. At the onset the child had loose stools and some vomiting. There was a slight cough. Examination revealed little. The child weighed 18 pounds and 8 ounces (8.4 kg). The temperature was 100.2. There was some postpharyngeal redness. Blood examination revealed red blood cells 5,000,000; hemoglobin 85 per cent; white blood cells 9,500; small lymphocytes 70 per cent; large lymphocytes 5 per cent; neutrophils 23 per cent; monocytes 1 per cent; eosinophils 1 per cent. There were no malarial plasmodia. Urine examination was negative except for a slight amount of sugar which was not present on a subsequent examination. Stool examination was negative. Both a Mantoux and a Pirquet test were negative. The appetite was never more than fair. As the child had not had any cod liver oil but only small amounts of viosterol, I placed him on 10 D cod liver oil and informed the mother that if the fever continued I wanted to have an agglutination test for *Alcaligenes melitensis*. The temperature did drop somewhat instead of running between 100 and 101 as it had been doing; it ran between 99 and 100. The child had frequent attacks of an infection of the upper respiratory tract and I pleaded with the mother and father to have a tonsillectomy and adenoidectomy performed, feeling that perhaps a chronic adenoiditis was causing the fever. In April 1931 the family left town and I did not hear any more about the child until March 22, 1933, when they returned. At that time the child had a cold and temperature of 99 and later 103. There was a profuse postnasal discharge. After this attack subsided the family finally consented to have the operation advised earlier. April 10 it was done. Since then the temperature has continued around 100 and 101 and then on some days it is around 99. The child seems to feel well but does not have much of an appetite at any time. I have also had the child take a series of ultraviolet ray treatments. He now weighs 29½ pounds (13.4 kg) and is 37¼ inches (94 cm) tall. Is this a case of idiopathic hyperthermia or what I have sometimes heard called growth hyperthermia? The mother told me that for a period of about one and one-half to two months while they were away he was free of fever. They were in Arkansas during the summer months. I can find nothing wrong with this child and still he has fever. Your opinion will be greatly appreciated.

PAUL R. MEYER, M.D., Port Arthur, Texas

ANSWER—This query brings up the subject of the cause of obscure fever in infancy and childhood. The answer to this frequent and difficult problem can be solved best by an exhaustive process of exclusion. Has he a chronic focus of infection somewhere in the pharynx, nasopharynx, ethmoid sinuses, lymph nodes of the neck, or in the thorax, or within the abdomen? Has he a pulmonary, cardiac or renal infection? Is there a latent rheumatic infection? All of these problems and many similar ones require thoughtful consideration before a functional diagnosis which is loosely covered by the term hyperthermia should be made. Does the fever disappear during rest and reappear during active muscular exercise? In such a case if nothing else is found one may assume that muscular activity and a labile temperature mechanism cause the elevation of temperature.

While these elevations of temperature in infants and young children are disconcerting to parents and physician alike, and while it is the duty of the physician to establish a positive organic diagnosis, if it is humanly possible, nevertheless there remains a group of these children in whom no definite cause can be found and who survive and become normal in spite of the temperature elevation. In these cases thermometry may be discontinued for a time and will not detract from the health of the child and will bring comfort to the mother and peace to the doctor.

ATABRINE—PI ASMOCHEIN

To the Editor—Advertisement by the manufacturer claims that five days' administration of atabrine is sufficient to destroy both schizonts and gametocytes. Other attractive qualities are claimed for this agent. Please inform me whether these claims are true and whether there is any great advantage in its use over quinine. Please discuss plasmodium.

M.D. Illinois

ANSWER—According to information received, Atabrine is a product of the I. G. Farbenindustrie in Elberfeld, Germany, and is proposed as a substitute or for use with "Plasmodium" in the treatment of malaria. It is sold in America by the Winthrop Chemical Company. The product is stated to be the dihydrochloride of a dialkylamino derivative of acridine (N,N-dimethyl-4-amino-6-methylacridine, Ger.). It is stated that on the basis of laboratory experiments it may be assumed that Atabrine primarily affects the schizont stage of the plasmodium (*Schizontenmittel*, Ger.) and, in contrast with Plasmodium, exerts no action on the gametes of *Plasmodium falciparum*, the causative agent of estivo autumnal malaria. Atabrine has not been accepted for New and Nonofficial Remedies nor has the Winthrop Chemical Company requested consideration by the Council on Pharmacy and Chemistry.

According to the preliminary report of the Council on Pharmacy and Chemistry (THE JOURNAL, July 9, 1927, p. 113), Plasmodium is a synthetic quinoline derivative developed in Germany and proposed for use in the treatment of malaria. For many years attempts have been made to find a substitute for quinine that would be cheaper, less bitter, less toxic and more specific than the natural drug. Plasmodium appears at least to represent a step forward in this search. However, according to von Oettingen (Therapeutic Agents of the Quinoline Group, American Chemical Society Monograph 64, 1933) it "cannot be considered as a substitute for quinine but it seems to be valuable when quinine cannot be used and as adjuvant in the administration of quinine on account of its specific toxicity for gametocytes which are more resistant to quinine than the schizonts. In small doses of 0.018 gram per day it may be a safe prophylactic against the transmission of malaria by mosquitoes."

Plasmodium is marketed by the Winthrop Chemical Company; this firm, however, has not submitted the evidence required to make the product acceptable for New and Nonofficial Remedies.

TREATMENT OF SYPHILIS

To the Editor—I read Queries and Minor Notes with interest and would like your advice in the following case. I have been treating a woman aged 27 for syphilis. Two years ago from another doctor she received five intravenous treatments of nearsphenamine and then had a negative Wassermann reaction. Last fall she developed sores on her hands which I diagnosed as syphilitic and the Wassermann reaction in February 1933 was four plus. Since that time she has received twelve intravenous injections of nearsphenamine and fourteen intramuscular injections of bismuth sodium tartrate 1.5 per cent. After the injections of bismuth were begun she noticed a tingling and numbness in her lower legs and ankles but I did not connect this with the medication. By July of this year she was having considerable trouble with her feet and wished to discontinue the treatment. She has refused any more treatment until the neuritis leaves her feet. What I should like to know is: What form of treatment should I give her now? Is there anything that can be done to clear up the neuritis? How many more intravenous and intramuscular injections should she have to get a full course of treatment? In May between the courses of nearsphenamine and the bismuth compound I let her rest for two weeks and a Wassermann test taken at that time was negative. Is this worth considering correct when she has had so much treatment? Do you think I would be safe in letting the treatment go and making blood tests periodically? Kindly omit name.

M.D. Pennsylvania

ANSWER—It would seem to be essential in this case to determine more exactly the nature of the neurologic disturbance and particularly its possible relation to neurosyphilis as a form of relapse. The treatment given two years ago was precisely of the type that would invite some serious form of recurrence at about the present time and the Wassermann test on the blood although positive, by no means establishes the nature or

extent of the relapse. The tingling and numbness in the legs and ankles may therefore be an expression of a neurorecurrence or of the continued progression of an uncontrolled neurosyphilis, asymptomatic when the patient was first seen. The proper procedure, therefore, would seem to be a careful clinical examination plus an examination of the spinal fluid, which should be complete and not confined merely to a Wassermann test. Lacking the information these examinations would afford, one proceeds entirely in the dark with the continuance of treatment and the patient may well find herself in a serious situation through her refusal to continue treatment, or the physician may be embarrassed by complications which a more careful examination could have prevented. Under no circumstances should the matter be allowed to rest in its present state or the problem evaded simply by the repeated taking of blood tests.

SENSITIVITIES TO DUST AND CHANGES IN TEMPERATURE

To the Editor—A man aged 42 suffers with frequent attacks of coryza, sneezing, lacrimation, itching of the nasal mucous membranes with watery discharge, fullness and pressure in the head, sweating of the head and scalp and sensations of cold and chilliness. He conducts a small grocery store and when he goes into the refrigerator or is in a draft the condition becomes worse. It has existed about four years and is more severe in winter than in summer. The symptoms are quite typical of hay fever but apparently the sensitivity is due to some substance to which he is continually more or less exposed. I would appreciate your suggestions and the general results expected by desensitization if the offending substance is identified by skin test. Kindly omit name.

M D Connecticut

ANSWER—The patient in all probability is sensitive to the dust in the store. This dust should be collected, the dust that is tracked into the store from the outside being avoided as much as possible. It should be collected from behind the counters under the counters and from the walls with an electrical whisk broom. The dust should be extracted in as concentrated a solution as possible, filtered through stone and diluted down serially. It can be used for diagnosis and therapy (Cooke, R A. Studies in Specific Hypersensitivity. *New Endologic Factors in Bronchial Asthma*, *J Immunol* 7:147 [March] 1922).

He is probably in addition sensitive to heat and effort or to cold. One cannot determine which from the history but specific methods of testing can be carried out (Duke, W W. Clinical Manifestations of Heat and Effort Sensitivity and Cold Sensitivity [Relationship to Heat Prostration, Effort Syndrome, Asthma, Urticaria, Dermatoses, Noninfectious Coryza and Infections], *J Allergy* 3:257 [March] 1932).

DOSAGE OF HEXYLRESORCINOL AS ANTHELMINTIC

To the Editor—I notice an answer to a correspondent in regard to the use of hexylresorcinol as an anthelmintic. In answer you give the dose as 0.1 Gm for each year of age up to 1 Gm. Now the only form of this drug with which I am familiar is Sharp and Dohme's Hexylresorcinol Solution S T 37. I consulted Dorland's Medical Dictionary and find the following: Hexylresorcinol. A white waxy stable solid. It is a powerful germicide with a phenol coefficient of 46. Dose 2½ to 10 minims (0.15 to 0.6 cc) three times a day. This bewilders me giving the dose of a solid in minims. Please set me right in regard to this. Please omit name.

M D, Iowa

ANSWER—Some solids are customarily measured by volume rather than weight, such as wheat and corn, but it would seem a bit awkward to measure out minim doses of the solid hexylresorcinol. The dosage of 0.1 Gm up to 1 Gm of crystalline hexylresorcinol for 1 year of age is an effective anthelmintic dose against ascariis and hookworm.

Tetrachlorethylene is in all probability as effective as carbon tetrachloride and theoretically, is decidedly preferable on account of causing no liver damage or any other intoxication that has been discovered. Clinically, it seems to be as effective as carbon tetrachloride and as far as we have been able to determine has produced no true intoxication. Like any anesthetic when taken by mouth it may cause slight temporary giddiness which should not be considered an intoxication. The only contraindication known against its use is in cases of mixed intoxication in which both ascariis and hookworm are present in which condition it may cause migration of ascariis with complication.

Hexylresorcinol has been found to be extremely effective against ascariis: reduction of 95 per cent or over having been obtained. It is less effective against hookworm but in the treatment of large numbers of cases an average reduction of 75 per cent in egg counts may be expected while better results have been obtained in carefully controlled cases.

INDUSTRIAL HAZARD FROM LACQUER USED IN MAKING ARTIFICIAL FISH BAIT

To the Editor—I have a young woman patient who works in an artificial fish bait factory where a great deal of Dupont lacquer is used in painting the bait. She continually has a severe rhinitis with the membranes of the nose practically closing the air passages. When she is away from the factory a few days she has no trouble so I feel that it is from the lacquer. Do you have any experience in what to do for this condition?

C PHILIP FOX, M D Garrett, Ind

ANSWER—The condition described may occur in certain individuals, especially if the solvent vapors are too concentrated in the workroom and if the person concerned has enlarged turbinates. Occasionally individuals react to solvent vapors, manifesting symptoms such as nausea, eye irritations and skin irritations, and the other persons employed in the same room show no reaction whatever. In some cases it is necessary to remove these individuals from this type of work.

If ventilation is not adequate to carry away the solvent vapors, steps should be taken to make improvements along this line. If the individual is the only one among a group working under the same conditions who is suffering from this irritation, it may be necessary to remove her from this type of work. If she has hypertrophied turbinates, possibly their removal will help to clear up the situation.

EFFECTS OF RADIATION ON PRODUCING ABORTION

To the Editor—I have a patient a woman aged 38 who had a rectal pruritus and was given at weekly intervals unfiltered x-ray treatments for a period of one minute for three treatments with the tube some 6 inches from the skin. No lead protection was used. About the time she reported for the first treatment of x-rays to the dermatologist she missed a menstrual period and showed some breast changes of pregnancy. About one week after the last x-ray exposure she commenced having uterine pains and passed some decidua. Did the x-ray exposure have anything to do with this abortion in your opinion? I do not know the voltage or milliamperage used in the treatment. I am not asking this question because there are any medicolegal questions involved but purely for information.

EARL B GERLACH M D Huntington, W Va

ANSWER—From 50 to 60 per cent of a skin unit dose has been found to be a little above the castration dose. This amount of exposure to x-rays results in abortion. It is possible to induce abortion by administering less than the castration dose. Without a knowledge of the voltage and amperage, it is impossible to estimate the dose of radiation administered in this case.

IMMUNIZATION OF CHILDREN

To the Editor—With the increasing number of biologicals offered for conferring immunities the problem of which and when to administer becomes confusing. Kindly give me as nearly as possible the ideal schedule for the average child without overdoing it. In other words, when and what immunizing administration should every child have to secure adequate protection without running unnecessary risks of anaphylaxis? Please omit name.

M D, Georgia

ANSWER—Every child should be vaccinated against smallpox and immunized against diphtheria. The child should be vaccinated against smallpox early in life. It has been shown that the earlier the vaccination is done, the less severe is the reaction and the less danger of complications. After the child has been successfully vaccinated against smallpox, he should be immunized against diphtheria. This may be done any time after the sixth month of life. Diphtheria toxoid, which contains no animal serum and consequently eliminates sensitization, is in common use. For children over 4 years of age toxoid antitoxin, prepared with goat or sheep serum, is preferred by many physicians because of the less severe local reaction.

Whether other immunizing agents should be given in the routine manner is still a question. In the presence of an epidemic, the appropriate immunizing agent should certainly be given.

EFFECTS OF IODIDE ON NASAL MUCOSA

To the Editor—Kindly send me information regarding the pharmacology of potassium iodide in large and in small continued doses over a long period of time on the nasal mucosa. Kindly omit name.

M D Chicago

ANSWER—There is not a doubt that some of the iodide is eliminated by the nasal mucosa and also that such elimination may occur without any obvious phenomena whether large or small doses are consumed and for a long time. On the other hand the symptoms of iodism may appear even after small doses given for a short time. Indeed they seem to occur more commonly after small doses given at short intervals during the day than after large doses given less frequently and after meals. The symptoms consist of a catarrhal inflammation of the nose.

and adjoining mucous membranes with swelling, softness and sponginess of the mucosa and profuse secretion, accompanied by sneezing, a burning sensation in the nose, and a sense of occlusion and oppression. There may be a loss of smell, and frontal or maxillary sinus pain. The symptoms disappear shortly after the suspension of the drug. It is probable that previous diseases of the nasal mucosa cause these symptoms to appear earlier and more intensely than is the case with normal mucosa.

SKIN ERUPTIONS AFTER PHENOBARBITAL

To the Editor—A patient presented himself to my office a few days ago to consult me concerning a peculiar eruption resembling psoriasis. The history of his case shows that he has had epilepsy for fifteen years and has been taking $1\frac{1}{2}$ grains (0.1 Gm.) of phenobarbital three times a day ($4\frac{1}{2}$ grains or 0.3 Gm. daily) for a period of fifteen years. I am interested to know whether the long continued use of phenobarbital will produce skin manifestations. This patient has been suffering intermittently from this skin condition for a period of nine months. The character of the lesions and the distribution do not conform to any of the common skin diseases with which I am familiar. Therefore I am led to believe that the drug might be the cause of his condition. Please advise me.

M D Rhode Island

ANSWER—Phenobarbital (luminal) is well known to have a tendency to produce eruptions of various kinds and it is entirely within the range of probability that the eruption may be due to it. The test of temporary discontinuance of the medicine and its resumption after the disappearance of the eruption will provide definite proof.

POSITION OF MOTHER WHILE NURSING BABY

To the Editor—What if any are the reasons for requiring a young mother each time she suckles her baby 6 weeks of age to do so lying down in other word go to bed? This mother made a good recovery and has been up and around several weeks feeling fine. The only reason she herself can give is that she is following Dr Bunde's book.

JOHN B MILLER M D Long Beach Michigan City Ind

ANSWER—There is no special reason why a woman should lie down either on a bed or on a couch to nurse her baby. In fact, it is better for her to sit up although it does not matter much whether she lies down or sits up, so long as she is comfortable. It is wise to warn the young mother not to look at the baby constantly while the latter is at the breast, because this not only strains the eyes of the mother and occasionally produces headaches but it also strains the muscles of the neck and back, which likewise may become the seat of pain.

MUSCULAR DYSTROPHY

To the Editor—Please outline treatment if any for pseudohypertrophic muscular atrophy in a boy aged 10 years. Please omit name.

M D Canada

ANSWER—There are two rather new methods of treating muscular dystrophy. 1 By hypodermic injections of epinephrine and pilocarpine on alternating days, 0.2 cc of 1 per cent solution of each. This is based on the not generally accepted theories of Ken Kure. 2 Glycine (glycocoll gelatin sugar) from 10 to 30 Gm daily by mouth. This treatment, proposed by the German physiologist Karl Thomas, has been tried at the Mayo Clinic with rather indifferent results (*Proc Staff Meet, Mayo Clin* 7 557 [Sept 28], 737 [Dec 28] 1932).

POLIOMYELITIS

To the Editor—In this community there is a mild epidemic of acute anterior poliomyelitis. Please advise on the following: 1 Is there any serum that has shown good results? 2 Is immune serum a proper treatment and should it be given early? Please omit name.

M D Pennsylvania

ANSWER—1 There is no commercial serum available with established curative action in epidemic poliomyelitis.

2 If by 'immune serum' is meant the serum from persons who have had the disease—convalescent serum—the answer is that it is quite in order to inject such serum the earlier the better. While opinion is divided as to the results of treatment with convalescent serum, its use seems logical and harmless.

TOXICITY OF HYDRAZOIC ACID

To the Editor—In your answer to Dr Cote (*THE JOURNAL* August 12 p 546) you give some references to work on the toxicity of hydrazoic acid. It is of interest to note that a full investigation of the toxicity of this acid was made by Letchworth Smith and myself thirty years ago in the Chemical Laboratory of Cornell Medical College New York. The results of this investigation were published in the *Journal of Medical Research* under the title 'The Physiological Action of Azonimid' volume VII No 4 1904 pages 421 to 473.

Book Notices

Light Therapy. By Frank Hammond Krusen, M.D., Director of the Department of Physical Medicine, Temple University School of Medicine, Philadelphia. Foreword by John A. Kolmer, M.D., Dr. P.H. D.Sc., Professor of Medicine, Temple University School of Medicine. Cloth. Price \$3.50. Pp. 186 with 33 illustrations. New York: Paul B. Hoeber, Inc. 1933.

Succeeding ages have practiced light therapy in accordance with limited experience, out of which arose unorthodox opinions and a literature based on empiricism. Modern biologic sciences have sought and attained concrete evidence of the therapeutic efficacy of light, as evidenced by the recent literature which formulates opinions on the basis of controllable facts. The aim of this book is to differentiate facts from current fallacies and to present a serviceable technique for the employment of various agencies used in light therapy. The author has drawn on authoritative sources to such a proportion that the work impresses one as a commentary rather than an exposition based on his personal experience, a characteristic amounting to self effacement. Theory is weighed against fact, physics is correlated with physiology and clinical results are shown to be dependent on biophysical factors. Separate chapters have been devoted to a review and an analysis of the physical and physiologic properties of light, the author defining the source and nature of light energy and concisely discussing its methods and techniques of administration with its dangers, limitations and indications. While the work offers a satisfactory evaluation of light therapy, embracing a range from infra-red to ultra-violet, its value would have been enhanced had the author included the recent conclusions of the Council on Physical Therapy. Perhaps certain minor shortcomings, for example, the misinterpretation of the effects of the so-called cold quartz rays on vitamin D are due to the completion of the book prior to the Council's announcement. On the whole, the book is a timely and practical contribution which may be accepted by general practitioners as a safe guide in light therapy.

Stop That Smoke! By Henry Obermeyer. Cloth. Price \$2.50. Pp. 259 with illustration. New York & London: Harper & Brothers, 1933.

Smog, the combination of smoke and fog is indicted, convicted and sentenced in this book for one of the high crimes and misdemeanors of the century. Destroyer of buildings, polluter of the air, robber of ultraviolet, foe of economy, thief of light—all these is smog. The book is a lengthy compilation of facts which all know more or less, though perhaps not in terms of the figures which the author quotes until their reiteration grows tiresome and the mind unused to thinking in terms of billions wearily slides over them with a simple realization that they are enormous which is after all perhaps all that is necessary. Little progress has been made in smoke abatement as compared with what has been done for the purification of the water supply; the author points out probably because smoke damage is invidious and not spectacular as may be the outbreak of epidemic water-borne disease. He makes a plea with the error of a crusader for elimination of smoke as an economic and public health measure with preservation of a certain art treasures from undergoing destruction from

exposure to smoke and other esthetic values as by-products scarcely less valuable than the central motives. He overlooks no possible interest or motive to which he might appeal. Near the end of the book are some practical chapters about how smoke abatement can be accomplished, from the great factory to the home furnace. Except that it might have been much briefer, this is a good and useful book which will probably, human nature being what it is, have much less of a salutary influence than it ought to have.

L'héliothérapie. Par le Docteur Henri Dausset, chef du service central de physiothérapie de l'Hôtel Dieu. IV. Actinothérapie. I. Papier. Price 15 francs. Pp. 115. Paris: Gruthier Villars & Cie, 1932.

This small volume is a condensed discussion of the clinical value of heliotherapy, being one of three dealing with actino-therapy. It discusses in six chapters the therapeutic application of heliotherapy in selected conditions on the basis of its physiologic effects. Beginning with a brief review of the physical nature of the solar spectrum, the book takes up the theories of light and radiation, the effect of light absorption by various atmospheric filters, and the methods used for its detection and measurement. These physical expositions are followed by a consideration of the technique utilized by the author and other authorities in various disorders, with particular reference to the combined values of open air and sunlight and their photochemical and physical properties influencing living organisms. Nudism is accepted by the author as a physiologic means of securing the full benefit of open air and sunshine and rejected as a fad with pornographic coloring. The author cites for this view the opinions of Viard, Mongeot, de Pathout, de Vachet and others to the effect that, when sanely employed, nudism will benefit the individual and the race. One of the most informative chapters is concerned with a discussion of how heliotherapy works. It deals with the mode of action and physiologic effect of sunlight and open air as related to various organs of the body. Attention is directed to the influence of cosmic rays, the so-called delta rays of Millikan. The author introduces the speculative thought that these deeply penetrating rays may have a powerful although an inexplicable physiologic effect. He feels that in the light of recent studies by Professor Piccard in connection with his research in the stratosphere, there is promise of new experience of value to the biologic sciences. The remainder of the book is devoted to the interpretation of the clinical effect of heliotherapy, a part of which considers irradiation of food material. The book has successfully presented virtually the entire problem of heliotherapy in a condensed form in accordance with the latest opinions on the subject.

Workmen's Compensation: Its Medical Aspect. By Sir John Collie, C.M.G., D.L., M.D., Consulting Medical Officer to the Ministry of Pensions. Cloth. Temporary price \$2.25. Pp. 160. Baltimore: William Wood & Company, 1933.

All those who are in any way associated with the administration of the medical phases of workmen's compensation in the United States will welcome this volume, which deals with the workmen's compensation acts of England in a thorough and convincing manner. The author presents in a lucid style and a concise form the growth of compensation and the legal and medical aspects of the medical phases of compensation as they have been modified from time to time. In his discussion of the growth of compensation he says:

It is thirty-six years since the first Act was passed and it may be opportune now to envisage the present position which certainly affords material for reflection. It was calculated by the Home Office in affording information as to the probable effect of the passing of the Act of 1897 that 150,000 accidents a year would fall within its scope. In the even principal industries for which accurate statistics are obtainable the number of cases of accident in which compensation under the present Act was paid in 1930 amounted to 461,137; in addition there were 2,303 uninsured employers who reported that they were paying compensation in respect of accidents sustained by their employees.

He makes the further comment:

It is to be hoped that the limit to which compensation is applicable has now been reached and that any future legislation will tend to be restrictive, although one realizes it is easier to give than to take away what has once been given.

It is significant that such statements might easily have been made about workmen's compensation in the United States. An excellent chapter, with illustrations taken from court rulings,

is devoted to the subject "What is an accident?" The discussion in the chapters on the law and medical examination and the law with regard to operations is well supplemented by quotations from court decisions. One chapter is devoted to the consideration of the position consequent on complete or partial recovery, and another sets forth the conditions surrounding return to work. Although the reader must always be conscious that the author is discussing workmen's compensation as it is operated in England, there is much of value in the principles enunciated. The author has treated a dry and complex subject in a delightfully entertaining manner.

Hints to the Young Practitioner By G. Fennels Smith M.R.C.S. J.R.C.I. Consulting Surgeon, Pence Memorial Hospital, Watford. Cloth. Price \$1.50. Pp. 150. New York & London: Oxford University Press, 1932.

This book, written for the young practitioner by a British colleague of considerable experience, is planned to make easier the way of the young man, exactly as the preceptor of the past did for the young apprentice. He therefore advises the young man in the selection of a practice, the features of general practice, the problems that arise in relationship to difficult cases, venereal diseases, conjugal relations, and the care of children. He discusses medical societies and hospitals, financial matters, vacations, and particularly the relationship of the physician to panel practice as it has developed in England. To an intelligent reader it seems that much of what the author writes ought to be guessed at by any other intelligent man, but in his presentation this author is exceedingly interesting, particularly because he recites cases from his own practice to illustrate his points. In his conclusions he suggests that too much civilization is responsible for most of the troubles that have come to the physician, and that part of his duty is to overcome these extraordinary refinements.

Melioidosis By A. T. Stanton C.M.G. M.D. F.R.C.P. Chief Medical Adviser to the Secretary of State for the Colonies and William Fletcher M.D. M.H.C.P. Studies from the Institute for Medical Research, Federated Malay States No. 21. Cloth. Pp. 59 with 37 illustrations. London: John Bale Sons & Danielsson Ltd, 1932.

This monograph consists chiefly of observations made in the Malay States over a number of years on the disease called melioidosis. It is a rare but deadly disease of man and animals, being found chiefly in rodents. Eighty-three human cases have been reported, all except two of which were fatal. They occurred in Burma, Malaya, French Indo-China and Ceylon. The authors believe it to be a more common disease than usually supposed. It is known to attack animals in the Malay States, Ceylon and the Dutch East Indies. In Kuala Lumpur it has been found in guinea pigs, rabbits, rats, cats, dogs, and once in a horse. Owing to the fact that almost any part of the body may be attacked, there are no cardinal symptoms on which a diagnosis may be made. The causative organism, *Bacillus whitmorei*, a member of the Pfeifferella, must be isolated before the true nature of the disease may be known. Infections of great virulence have a sudden onset and may resemble cholera, and in the septicemic cases death has occurred within the first seventy-two hours. When the initial infection is less virulent the disease may resemble plague, malaria, typhoid, liver abscess, infective endocarditis or general tuberculosis. *Bacillus whitmorei* is easily cultivable on all common laboratory mediums, one of its chief cultural characteristics is its growth on 5 per cent glycerin agar. On this medium growth is rapid and within forty-eight hours the colonies take on a characteristic wrinkled appearance resembling the surface of a mold. While *Bacillus whitmorei* is closely related to *Bacillus mallei* serologically and immunologically, it can be distinguished from the latter organism chiefly by its motility in young cultures and its corrugated appearance on glycerin agar. The organism is highly resistant outside the body, being able to resist drying and to live in water for comparatively long periods. It is sensitive to heat and the action of ordinary disinfectants. Little is known about its method of dissemination. There is no evidence of direct infection from man to man and the authors believe that infection probably takes place through the consumption of food contaminated with the feces of rodents. The illustrations portray clearly the various aspects of the disease in man and in animals and also the appearances of the colonies of the organism when grown on various mediums.

Acidosis and Alkalosis By Stanley Graham M.D. F.F.F.P.S. Leonard Cowie Lecturer on the Medical Diseases of Infancy and Childhood University of Glasgow and Noah Morris M.D. B.Sc. D.P.H. Lecturer in Biochemistry University of Glasgow. Cloth. Temporary price \$2.50. Pp. 203 with 23 illustrations. Baltimore: William Wood & Company, 1933.

This small book fulfils the purpose, stated in the preface, 'to give a general survey of the subject and its application to disease keeping in mind the needs of those not versed in recent chemical physiology.' The introduction offers a simple explanation of the acid-base equilibrium of the body and is followed by an elucidation of the reaction of the blood. Van Slyke's classification of disturbances of acid base balance is explained and is followed by Haldane's classification. The body defenses against alkalosis and acidosis are detailed together with methods for their determination. The last two thirds of the book is occupied with an application of chemical physiology to clinical medicine. The essential chemical features of diabetes, nephritis, gastro-enteritis, cyclic vomiting, ketosis, salicylate poisoning, anesthesia, acidosis, tetany and pyloric stenosis are presented and logical methods of treatment are suggested.

The Practitioners Library of Medicine and Surgery. Volume IV. Non-traumatic Surgery [George Blumer, Supervising editor.] Associate editor: Theodore S. Morse Jr. B.A. M.D. Surgeon to the Eastern Maine General Hospital, Bangor. Cloth. Price \$10. Pp. 1144 with illustrations. New York & London: D. Appleton & Company, 1933.

In this complete system of medicine and surgery, nontraumatic surgical conditions have been separated from the traumatic. Hence this volume is concerned with lesions of the skin and subcutaneous tissues, tumors, diseases of the breast, surgery of the neck, diseases of the thyroid gland, surgery of the brain and spinal cord and of the peripheral nervous system, surgery of the heart, the blood vessels and the chest, also of the gastro-intestinal tract as a whole, the lymphatics, the spleen, hernia, bones and joints, the urinary tract and the genitalia. There are some hundreds of illustrations which have been well chosen. The vast amount of material included in the book makes it almost an outline rather than an extended consideration of any single subject. Nevertheless it provides much immediate practical information, especially for general practitioners who may be considered primarily users of a book of this character. There are extensive considerations of technique, with illustrations taken in many instances from other works. However, many of the pictures seem to have been made especially for this volume. The authors have been chosen because of previous contributions on the subjects they discuss. It is interesting that the majority of the authors are not the professors of surgery whose names are most frequently found in medical periodical literature but in most instances associates, instructors, and assistants in various surgical departments. On the whole, they have done their work well, so that the book constitutes a most useful reference. The vast majority of general practitioners will, of course, be most interested in those sections dealing with hernia, infections and the bones and joints rather than with the intimate details of surgery of the brain and spinal cord. The volume has an excellent index, which adds also to its usefulness.

Die Bruchoperation nach Bassini Von Doktor Attilio Catterina, o. o. Professor der chirurgischen Operationslehre an der kgl. Universität in Genua. Cloth. Price 12 marks. Pp. 56 with 16 illustrations. Von Valer Horatius Gaigler. Berlin: Urban & Schwarzenberg, 1933.

This is limited to a detailed description of the Bassini operation for inguinal hernia, with colored illustrations showing the surgical anatomy and technique of each step. The author was an assistant to Bassini and dedicates the volume to his master and states that, since Bassini first described his operation, more than forty years ago, numerous modifications have been suggested by various surgeons. Some of these have been advanced as new operations and some have ignored the fundamental purpose of the original operation and consequently have been to its discredit. Surgeons, in general, are not carrying out all the steps of the operation in accordance with the technique suggested by Bassini. This is partly at least, due to the fact that Bassini in his original contribution (strangely enough the exact reference appears nowhere in the volume) was too brief in his exposition and the illustrations, while excellent, were too few and were limited to the purely anatomic part of the operation. Perhaps for this reason, too, the details of the operative technique

as described in the modern works on surgery differ greatly from Bassini's. The author, as a student of Bassini's, presents this new volume to correct these errors. He describes the operation step by step illustrating each with a full-page colored drawing. These drawings are unusually good, show the field life size, and greatly enhance the detailed written description of each step. The last thirteen pages of the book discuss the treatment of special complications encountered during the operation, as hernia and hydrocele, hernia and varicocele, inflammations of the testicle, particularly tuberculosis, tumors of the testicle, special disorders of the hernial sac, as tuberculosis, echinococcus, tumors and foreign bodies in the hernial sac, hernia and undescended testis, special and rare types of hernia, as hernia of the bladder, supravesical hernia, intra-parietal and interstitial inguinal hernia, inguinopropertitoneal hernia and sliding hernia, and injury to the ductus deferens. It ends with a discussion of late recurrence and its treatment. The book is unique, interesting and valuable for both the beginner in surgery and the experienced surgeon.

Some Factors in the Localisation of Disease in the Body. By Harold Burrows. CBE, FRCS. Assistant at the Research Institute of the Cancer Hospital (Free). Cloth. Price \$4.50. Pp. 299 with 8 illustrations. Baltimore: William Wood & Company, 1932.

The author has collected in this interesting volume the various factors that have to do with the permeability of the blood vessels and tissues. The book is divided into three parts. The first part is concerned with the permeability of the capillary endothelium to various soluble and insoluble substances and dyes under different conditions, followed by an account of the penetration and localization of the common bacteria and viruses. The second part deals with the relation of such permeability and localization to various disease processes and inflammations. The third part discusses the practical importance of the factors described and their importance in the understanding of infections and tumor metastases. Valuable therapeutic suggestions are given.

Material Media Pharmacology and Therapeutics. By Maude B. Muse, B.S., A.M. Assistant Professor in Nursing Education at Teachers College, Columbia University. Cloth. Price \$2.75. Pp. 627 with 71 illustrations. Philadelphia & London: W. B. Saunders Company, 1933.

If there is such a thing as a book being 'too good' for the purpose for which it is intended the present one is an example. A good textbook for a review course for a medical student, it seems hardly the book for a nurse. Quite a bit of it—that portion referring to experimental pharmacodynamics—might have been deleted or printed in small type for optional reading, with considerable improvement in its value as a textbook for nurses. The fact that the nurse does not need the same kind of instruction as the doctor seems to have been overlooked by the author. That portion on the other hand, devoted to physical therapy and psychotherapy, even though richer than most other books for nurses, might well have been considerably enlarged and a chapter on occupational therapy added.

Epidemiological Study of Scarlet Fever in England and Wales Since 1900. By Hilda M. Woods. Medical Research Council Special Report Series No. 140. Paper. Price 1s 3d. Pp. 61 with illustrations. London: His Majesty's Stationery Office, 1933.

This pamphlet is an account of the study of the statistics on scarlet fever and its spread in the last thirty years. Many interesting facts are brought out particularly the relation of the spread of the disease to conditions such as to crowding, also the failure of the control of the disease by means of isolation. Interesting comparisons are made of the mortality figures present and past. The study is complete and is of especial interest to epidemiologists.

Social Problems and Social Processes. Selected Papers from the Proceedings of the American Sociological Society, 1932. Edited by F. M. S. Rodgers. Cloth. Price \$1.50. Pp. 144. Chicago: University of Chicago Press, 1933.

This volume makes available the selected papers from the proceedings of the American Sociological Society for 1932. It discusses the effects on various classes of the social processes now going on including the rural groups, Negroes, Chinese, Russians and Asians. There is also a general discussion of the nature of social processes and their analysis.

The Health School on Wheels. By J. Mace Andress, Ph.D., and I. H. Goldberger, M.D., Assistant Director of Health Education, New York City Public Schools. The Story Series in Health. Cloth. Price 80 cents. Pp. 399 with illustrations. Boston & London: Ginn & Company, 1933.

This book is intended for the sixth grade child. It takes the sixth graders on sightseeing tours, of which there are twenty-six. In these tours various health subjects are considered, such as water supply, markets, restaurants, barber shops, factories, mosquito breeding places, recreation centers and schools. It gives consideration also to first aid, fire fighting, noise, housing, country vacations, and milk. The information presented is authentic, the style is bright and interesting. Contrasts are offered between pioneer days and today. Illustrations are frequent and satisfactory. The tours are followed by questions and also by useful lists of new words which have been learned on that particular trip. Interesting bits such as the fact that Abraham Lincoln was the first president of the United States "to splash his way to cleanliness in a White House bath tub" enliven the text, intrigue the interest and make the dull subject of health palatable to the inquiring youngster. There is a good glossary and index. Suggestions to the teacher for weighing-measuring are up to date. No height-weight tables are given, but instead a chart is published on which the child's progress in height and weight can be recorded, thus substituting progress in the child's own growth as a criterion for the now discredited comparison with height-weight standards of the group. Not only is this an excellent textbook for sixth graders, but, in communities where the schools do not use it, physicians should find it useful to recommend to parents as a health book to put into the hands of youngsters.

Thérapeutique médicale. VI. Cœur et sang. Par M. Loeper avec la collaboration de MM. A. Lemaire, E. Donzelot, Ch. Aubertin, A. Clère, G. Marchal, R. Boigez, M. Monquin, P. Emile Well et A. Tzonck. Paper. Price 45 francs. Pp. 312 with 31 illustrations. Paris: Masson & Cie, 1933.

This is the sixth volume of a series, in the French language, sponsored by the department of therapeutics of the Faculty of Medicine of Paris. It takes up, in practical detail, the various important remedies employed in diseases of the heart and of the blood. Like the other books of this series, it constitutes a valuable addition to the reference library of any practicing physician capable of reading French and is invaluable to the teacher of therapeutics as representing the French point of view and practice.

The Duties of Ohio Public Health Commissioners. By W. W. Charters. Director, Bureau of Educational Research, Ohio State University and Darwin A. Hindman, Associate Professor of Physio-Education, Ohio State University. Bureau of Educational Research Monographs, Number 17. Ohio State University Studies. Edited by Josephine H. MacLately, Ph.D. Paper. Price \$1. Pp. 70. Columbus: Ohio State University, 1933.

This is a statistical analysis of the activities of public health activities in Ohio based on the work of 56 out of a total of 180 commissioners. It led to the establishment of a course for public health officers with a curriculum of work now being done by the majority of health commissioners in Ohio. The activities are collected into headings such as laboratory and engineering activities, vital statistics, control of disease, administrative activities and educational functions.

Handbook of Tuberculosis Schemes for Great Britain and Ireland. Seventh edition. Paper. Price 7s. Pp. 162. London: National Association for the Prevention of Tuberculosis, 1933.

This edition of the handbook is a valuable compilation for the use of British physicians. It sets forth in a complete and well organized manner the tuberculosis problem and the activities that are in movement against the disease. This information being given for shires and boroughs enables one to study the British situation in detail. Separate sections of the report deal with England, Wales, Scotland and Ireland. There is also a list of residential institutions which includes a description of the institution and information as to its capacity. The interest of this report to the American physician is largely in the information it gives about the treatment of tuberculosis through governmental agencies which seems to leave little or nothing for the private practitioner to do. For example, in the borough of Southport, having a civil population of 77,280, residential in character, with a total death rate of 1,496 per

hundred thousand and a tuberculosis death rate of 63 per hundred thousand, there is a tuberculosis dispensary open one day a week and a sanatorium available with thirty-six beds. There is no open-air school, however. There is a chief administrative officer and an assistant tuberculosis officer. In other boroughs of varying sizes, similar situations prevail. The book is obviously a reference volume for the British practitioner but it shows plainly what the effects on medical practice are of a socialized system of practice such as obtains in Great Britain.

Medicolegal

Evidence Scientific Tests, Lie Detector—The defendant was charged with bank robbery. In the course of his trial his counsel offered to prove, by a test on the defendant with an instrument known as a "lie detector" that when the robbery was committed the defendant was not in the city where it occurred and that he was not guilty. The offer described the "lie detector" and claimed that it had been found to give a continuous quantitative differential blood pressure and pulse curve, that one guilty of a crime becomes disturbed and has distinct emotional disturbances when questioned with reference to the details of a crime which he has committed, that such emotional disturbances are recorded on the "lie detector" above described, that this "lie detector" has been used in over 10,000 cases and that seventy-five per cent of those upon whom the lie detector has been used have confessed their guilt upon completion of a second test with the said lie detector. The trial court refused to admit the proffered evidence and the defendant was convicted. He then appealed to the Supreme Court of Wisconsin, alleging the exclusion of this evidence as error.

On the question raised by this assignment of error said the Supreme Court, there has been only one reported decision. In *Fry v. United States* 54 App. D. C. 46, 293 F. 1013, 34 A. L. R. 145, the defendant had submitted to a deception test, but the trial court refused to allow the scientist who made the test as an expert to testify as to the results. In that case the Court of Appeals of the District of Columbia said:

Just when a scientific principle or discovery crosses the line between the experimental and demonstrable stages is difficult to define. Some where in this twilight zone the evidential force of the principle must be recognized and while courts will go a long way in admitting expert testimony deduced from a well recognized scientific principle or discovery the thing from which the deduction is made must be sufficiently established to have gained general acceptance in the particular field in which it belongs.

We think the systolic blood pressure deception test has not yet gained such standing and scientific recognition among physiological and psychological authorities as would justify the courts in admitting expert testimony deduced from the discovery, development and experiments thus far made.

The Supreme Court of Wisconsin was not satisfied that during the ten years that had elapsed since the above cited decision was rendered the lie detector had progressed from the experimental to the demonstrable stage. The court quoted Dean Wigmore's Principles of Judicial Proof (ed. 2) 1931:

Looking back at the range of possibilities for experimental psychometric methods of ascertaining concrete data for valuing testimonial evidence, it will be seen that thus far the only new psychometric method that has demonstrated any utility is the blood pressure method which detects lies. The record of psychometric achievement with testimony is still meager. The conditions required for truly scientific observation and experiment are seldom practicable. The testimonial mental processes are so complex and variable that millions of instances must be studied before safe generalizations can be made.

Dean Wigmore's statement said the court, seems to offer little comfort to one who contends that the lie detector is past the experimental stage. It may have some utility now and may ultimately be of great value in the administration of justice, but a too hasty acceptance of it may bring complications and abuses that will overbalance whatever utility it may be assumed to have. The present necessity for elaborate exposition of its theory and demonstration of its practical working in order to convince the jury of its probative tendencies, together with the possibility of attacks on the soundness of its underlying theory and its practical usefulness may easily result in a trial of the lie detector rather than the issues in the cause. Moreover if

the defendant in a criminal case is to be permitted to have tests taken outside of court and then to produce expert testimony as to the results of the tests when these are favorable to him, without the necessity of taking the stand or submitting to tests by the prosecution, the way would seem to be open to abuses that would not promote the cause of justice. The Supreme Court of Wisconsin therefore concluded that the refusal of the trial court to admit the testimony was not error and affirmed the judgment of conviction—*State v. Bohner (Wis.)*, 216 N. W. 314.

Malpractice Criteria of Competence of Physicians in Rural and in Urban Communities—The defendant, an exodontist of Louisville, Ky., extracted one of the plaintiff's teeth. An infection set in and, attributing it to the neglect and unskillfulness of the defendant, the plaintiff sued. The lower court gave judgment for the defendant whereupon the plaintiff appealed to the Court of Appeals of Kentucky. It was contended that the trial court erred in instructing the jury that the term "ordinary care and skill" mean such care and skill as are generally employed by ordinarily careful and skillful exodontists in the community of Louisville, under like or similar circumstances. A similar instruction said the court, was condemned in *Burl v. Foster* 114 Ky. 20, 69 S. W. 1096, when the court said:

We think the sounder rule is not that the physician's skill and degree of attention should be measured by those of his community but by such as is exercised generally by physicians of ordinary care and skill in similar communities.

In reaching that conclusion in the *Burl* case, however, the court continued a premise was that the operation was performed by a local physician in a small village where there were insufficient comparative standards by which to measure the degree of skill. There is no disposition now to depart from that rule when the conditions or the locality are similar to those involved in that case. But the question here is whether the same rule should apply in a city of some 350,000 inhabitants, where there are many skillful practitioners of the profession. The court was unable to regard as error the instruction which required the defendant to exercise such care and skill as were generally employed by ordinarily careful and skillful practitioners of the same class in the community of Louisville.

The judgment of the trial court for the defendant was affirmed—*Lanner v. Sanders (Ky.)*, 56 S. W. 2d 718.

Evidence Mortality Tables Admissible, Disclosure of Employment of Witness by Defendant's Insurer Compellable—In an action for damages for personal injuries in which the evidence shows that the injuries to the plaintiff are permanent it is not error for the trial court to receive tables of life expectancy in evidence. If the defendant carries liability insurance and the physician called as an expert witness by him is employed by the defendant's insurance company, it is proper for the trial court to permit such facts to be elicited from the physician on cross examination, since this fact would tend to affect the weight of his testimony—*Lyons v. Joseph (Neb.)*, 246 N. W. 839.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Physiology, Baltimore

105 1250 (July 1) 1933

- Influence of Desiccated Thyroid Gland Thyroxine and Inorganic Iodine on Storage of Glycogen in Liver of Albino Rat Under Controlled Conditions H C Coggeshall and J A Greene Indianapolis—p 103
- Relationship of Adrenal and Thyroid Glands to Excised Muscle Metabolism J E Davis and A B Hastings Chicago—p 110
- Reflex Reversal and Interaction of Allied Vestibular Reflexes R Lorente de No St Louis—p 122
- Study of Blood Volume Regulation and Blood Composition in Experimental Hydræmia I Regulation of Blood Volume D B Calvin A H Smith and L B Mendell New Haven Conn and Columbia Mo—p 135
- Studies in Physiology of Vitamins VII Effect of Experimentally Induced Hyperthyroidism on Vitamin B Requirement of Pigeons G R Cowgill and M L Palmeri New Haven Conn—p 146
- Fundamental Chemical Changes in Contracting Mammalian Muscle. J Sacks and Wilma C Sacks Ann Arbor Mich—p 151
- Studies on Cerebral Cortex II Localized Representation of Hopping and Placing Reactions in the Rat C M Brooks Boston—p 162
- Effects of Theelin and Theelol in Latent Tetany F Mathieu and B O Barnes Chicago—p 172
- Diurnal Cycle in the Liver of the White Rat II Food a Factor in Its Determination G M Higgins J Berkson and Eunice Flock Rochester Minn—p 177
- Absorption of Glucose by Chronic Loops of Colon G E Burget P H Moore and R W Lloyd Portland Ore—p 187
- Preparation Identification and Assay of Prolactin A Hormone of the Anterior Pituitary O Riddle R W Bates and S W Dykshorn Cold Spring Harbor Long Island N Y—p 191
- *The Basal Level of the White Cell Count in Man Malvina Schweizer New York—p 217
- Mode of Action of Secretagogues (Liver Extract) in Promoting Gastric Secretion M S Kim and A C Ivy Chicago—p 220
- Effect of Amniotin on Basal Metabolism of Pats and Rabbits T C Sherwood M Savage and J F Hall Lexington Ky—p 241
- Carbohydrate Metabolism of Heart During Ventricular Fibrillation D R Hooker and N D Kehar Baltimore—p 246

"Basal Level" of White Cell Count—Schweizer made white cell counts on fifty subjects while at rest and during mild activity. She has not confirmed the existence of a 'basal level' as described by Garrey. Of the fifty subjects, twenty-six showed no significant difference in the two counts while ten showed an increase and fourteen a decrease in activity. The white cell counts taken on subjects before rising did not all fall into the range between 5,000 and 7,000 in fact counts as low as 4,700 and as high as 11,500 were found. Similarly, during activity the counts were found to range from 3,500 to 11,500.

Delaware State Medical Journal, Wilmington

7 129 150 (June) 1933

- Vaginal Hysterectomy W F Preston Wilmington—p 129
- A Few of the Less Common Complications in Surgery J C Pierson Wilmington—p 135
- Why Potassium Iodide Should Not Be Used in Treatment of Tuberculosis C C Cooks Frankford—p 137

Potassium Iodide and Tuberculosis—Cookes states that the tuberculous process in the lungs is the deposition of lime salts about the necrotic area. Tricalcium phosphate is the material that walls off and seals up the diseased area. When potassium iodide is administered it ionizes into positive potassium and negative iodine. Iodine is a powerful oxidizing agent and the water present which it ionizes into positive hydrogen and negative hydroxide ions is caused to liberate negative oxygen ions which acting on the insoluble tricalcium phosphate barrier cause it to break down into the soluble calcium hydrogen phosphate and the soluble calcium hydroxide thereby allowing the necrotic and caseous process to spread and increasing the chances of a break and of a consequent hemorrhage.

Journal of Bacteriology, Baltimore

25 545 654 (June) 1933

- Blood in Cases of Unexplained Gastric Acidity W S Pollard San Francisco—p 599

Agglutination Reaction in Chronic Arthritis—Nicholls and Stansby observed that a high proportion of patients with rheumatoid arthritis give positive agglutination reactions to a specific type of hemolytic streptococcus. In patients with advanced joint involvement, higher average titers are obtained than in those with less involvement. The duration of the disease and the age of the patient play unimportant parts in the strength of the agglutination. Following the onset of the disease there is a gradual increase in the agglutination titer, which reaches its maximum in six months, on the average while following recovery of the patient the agglutinins tend to diminish and eventually to disappear. This reaction of serum in rheumatoid arthritis appears to be a true immunologic response. Other forms of arthritis do not give positive results in agglutination tests with typical strain streptococci.

Heat Cramps—Talbott and Michelson give a clinical description of five cases of heat cramps with a chemical study of the blood and urine. If the cause of heat cramps is essentially a loss of salt and water from the body tissues, treatment should provide for their restoration. The most rapid replacement of salt and water is by means of intravenous saline solution. The authors used only sodium chloride. In addition to the saline infusions, an exclusive milk diet was given during the first twenty-four hours. It is possible to prevent cramps by providing a daily supply of salt greater than that lost in the sweat. This amount may be determined by knowing the approximate amount of chloride excreted in a twenty-four hour specimen of urine. Less than 3 Gm of salt per day in the urine does not provide for a satisfactory margin of safety. Fresh cow's milk has an average salt concentration of about 0.3 per cent, and this provides fluid as well as salt. Salted drinking water (sodium chloride from 0.25 to 1 per cent) has been used successfully in the prevention of heat cramps among soldiers in the United States Army. Barley water and salted beer are used by certain local groups of colliers in England. It is possible that no salt need be taken between meals if the food is liberally salted at meal time. The necessary amount of salt to prevent

cramps is a function of the individual's susceptibility and of the amount lost in the sweat at a given temperature

Sympathetic Ganglionectomy—Craig and his associates made continuous observations of surface temperature, before and during sympathetic ganglionectomy, on all four extremities of four subjects with Raynaud's disease and thromboangitis obliterans. General anesthesia alone produced maximal vasodilation in Raynaud's disease and thromboangitis obliterans. Severance of the sympathetic nerves did not cause additional vasodilation. In Raynaud's disease a prompt and uniform vasodilating response was observed in the peripheral vessels of all four extremities, but in thromboangitis obliterans uniform response was absent because the occlusive process in the vessels of all four extremities is never the same in thromboangitis obliterans. The graphic records made with anesthesia at the time of operation serve as a check on preoperative studies carried out with other vasodilating agents. If satisfactory rises in the surface temperature of the involved extremities are not observed after induction of general anesthesia, it is evident that an additional rise will not develop after interruption of the sympathetic innervation. General anesthesia constitutes a satisfactory method for investigating thermal changes in cases of thromboangitis obliterans, Raynaud's disease, vasospastic scleroderma and arthritis, prior to and during sympathetic ganglionectomy. Valuable information may be obtained regarding the amount and extent of vasospasm in the vessels of the extremities particularly in the collateral circulation of subjects with thromboangitis obliterans, and the method gives accurate information regarding the degree of the occlusive process in this group of cases. Vessels of patients who are refractory to or react poorly to other vasodilating agents will usually undergo maximal vasodilation when general anesthesia is administered.

Recovery from Barbitol Poisoning—According to the experiments of Gower and Van de Erve, diuresis hastens recovery from barbitol poisoning. Its importance in the therapy of poisoning by other members of the barbituric acid series is not established. For the optimal rate of recovery from barbitol poisoning the diuresis should be adequate in amount without overtaxing cardiac and renal function and should be maintained hour by hour through the recovery period. The authors discuss several types of diuresis. The use of picROTOXIN as an antidote for the acute depression of barbitol does not preclude the importance or value of diuresis.

Flavobacterium Orchitidis—Sherwood isolated a new organism from the spinal fluid in a treated case of meningitis. It was apparently in pure culture and extensively phagocytized. Bergy has suggested that it be called *Flavobacterium orchitidis*. Its relationship to *Flavobacterium whitmorei* is being investigated. The organism presented short rods with rounded ends showing bipolar staining, occurring singly and in short chains. They were motile, gram negative and capsulated and did not produce spores. A gelatin stab formed rapid crateriform liquefaction. The agar colonies were circular, slightly raised, thick and opaque, were slightly brown in seventy-two hours, and showed a somewhat irregular margin. The glycerol agar slant was thick, mucoid and cream colored. The broth was turbid with a pellicle. There was coagulation with acid production and peptonization in the litmus milk culture. Growth was vigorous on potato medium, which was slightly brown in seventy-two hours. Indole was not formed, nitrates were reduced, blood serum was liquefied, and hydrogen sulphide was not produced. Growth on blood agar plates showed hemolysis and methemoglobin. Acid was produced in dextrose, lactose, maltose, sucrose and mannitol. The organism is quite virulent for guinea pigs and rabbits. Males develop acute orchitis following intravenous inoculation. There is considerable evidence suggesting that a soluble toxin is produced. Focal lesions in the liver, spleen and lungs are also produced.

Palm and Fork Test—Becker describes the palm test for deafness, which consists in pressing the palm of the hand over the ear to be tested while a vibrating tuning fork is applied to the opposite mastoid. On comparing the prolonged bone conduction produced by tympanic disease, finger and palm obturations, it will be observed that the palm obturation almost invariably exceeds that of the others, both in the duration and the intensity. In bilateral normal hearing, when a vibrating tuning fork is put on the vertex and one ear is occluded with a finger, the sound will become localized in the obstructed ear. In a case of unilateral conductive deafness, when the handle of a vibrating fork is set on the vertex the sound will lateralize faintly or strongly, depending on the degree of the involvement of the tympanic structures in the deafened ear.

Arteriosclerosis and Diabetes Mellitus—Lehnher reports the chemical analyses for the lipids calcium and phosphorus content of twenty-five nondiabetic adult aortas, twenty-five diabetic adult aortas and six nondiabetic children's aortas. The process of atheromatosis is accompanied by definite changes in the lipid deposit lipid allocation and calcium and phosphorus deposition which are similar in the diabetic and the nondiabetic aortas. The diabetic aortas differ from the nondiabetic aortas in having exaggerated lipid changes and more calcification. The aortas from the diabetic patients of middle and later life show lipid changes and increased calcium and phosphorus deposition comparable with nondiabetic aortas of an older age. The diabetic aortas show more marked calcium and phosphorus deposition than nondiabetic aortas with similar cholesterol deposits. The duration of the diabetes in the adult patients had no definite relationship with the chemical observations in the aortas. Severe diabetes of two years duration in a child was associated with greater lipid but less calcium and phosphorus deposition in the aorta than was found in an aorta from a diabetic child having had uncontrolled diabetes of eight years' duration.

Peptic Ulcer—Stephenson treated thirty-six cases of peptic ulcer by the intravenous synergistic method of Pitkin, that is, with a preparation composed of lipins, lipoids emetine and a protein. The author believes that the intravenous administration of 6 cc of the preparation, every third day for three doses, will render every patient with peptic ulcer symptom free provided the diet is confined to fresh or malted milk, cream, butter-milk, soft-boiled or raw eggs, broths and soups, cereals, starch rice and bread puddings baked or mashed potatoes, plain ice cream ices and sponge cake. Coffee, tea and alcoholic beverages are prohibited. After the sixth dose baked, broiled or boiled fresh fish and chicken (white meat), peas, squash spinach, mashed carrots asparagus, fruit juices and stewed fruits (except berries) may be added. After the fifth week all dietary restrictions are dismissed with the exception of alcoholic beverages and preserved meats or fish. It is preferable to give the injection when the stomach is empty as the reaction is almost immediate and if it is given after meals vomiting may occur. In the milder cases there is freedom from pain after the first injection. Six injections at intervals of three to four days usually suffice in the milder cases. Patients who have suffered for a long time with marked gastric or duodenal lesions may require eight doses the subsequent doses being given a week apart. The maximal number of injections for one course is ten. If a second course of treatment is required from six to eight weeks should intervene. The solution may be injected into the muscles.

of the arms or the buttocks, if intravenous injection is contra-indicated. In hemorrhagic cases the injection is repeated every second day.

Operation for Rhinophyma—Eller reports four cases of rhinophyma in which he obtained good cosmetic results by a relatively simple procedure. The superfluous tissue was pared off under local anesthesia until the nose was shapely. Later, when the skin had grown over the denuded areas it was treated by applications of x-rays, trichloroacetic acid or phenol. Each patient regained a shapely nose without conspicuous scars.

Hay Fever Treatment—Figley believes that the advantages of the continuous method of treatment in hay fever are that 1. After the protective dose is once reached the number of office visits required is lessened appreciably. 2. Treatment is less likely to be interrupted by illness or vacations. 3. Treatment may be started any time. 4. After monthly treatments have been sufficiently established results are invariably better than by the interrupted method. 5. There is good reason to

believe that a clinical cure can be accomplished in much shorter time than by the interrupted or seasonal method. One other beneficial feature of this method is that patients are kept under observation frequently enough and long enough for other manifestations of allergy to be recognized and corrected. Many hay fever patients have other allergic manifestations, particularly food sensitizations, such as eczema, migraine or colitis. In the author's series of 125 cases treated continuously for two years or more twelve (10 per cent) have attained a clinical cure. Not one of them has had any symptoms for the past two years and in all the skin tests to their specific causative pollens are negative. Most of these were cases of average sensitivity in which considerable immunity had been acquired before treatment was begun.

*Treatment of Undulant Fever in Man with Detoxified Vaccine and with Antiserum. Preliminary Note. A. E. O'Neil. Cincinnati—p. 438.

Scarlet Fever Antitoxin—Stevenson and his associates observed the therapeutic effects of scarlet fever antitoxin in eighty-four controls, seventy-four patients treated with antitoxin A and thirty-eight treated with antitoxin B. The duration of the period of eruption in the combined groups treated with antitoxin was 4.4 days as against 6.8 days in the control group. The antitoxin had no apparent influence on the duration of the interval before desquamation began nor did it have a pronounced influence on the desquamation period. There was a definite tendency for the desquamation to be localized and mild in character in the serum-treated patients but to be generalized and marked in the controls. An analysis of the temperature records failed to reveal any definite febrile reduction following an administration of antitoxin. Excluding serum sickness, there were 75 per cent fewer major complications (cervical adenitis, otitis media, mastoiditis, nephritis and toxic arthritis) in the serum-treated than in the control group. Of the serum-treated patients, 66.3 per cent developed serum sickness of varying degrees of severity. A previous injection of serum seemed to be the most important predisposing cause of serum sickness. Of the patients who had received a previous injection of horse serum in any form, 87.2 per cent developed serum sickness and of those who had previously received serum only in the form of diphtheria toxin-antitoxin, 85.3 per cent developed serum sickness. In the group of patients who had received no previous injection of serum, 40.8 per cent developed serum sickness. In this group the incidence of serum sickness seemed to be directly influenced by the volume of serum injected, since 66.7 per cent of the patients receiving 20 cc of serum (antitoxin A) and 16 per cent of those receiving 8 cc of serum (antitoxin B) developed serum complications.

Undulant Fever Treated with Detoxified Vaccine—O'Neil treated five cases of undulant fever with detoxified Alcaligenes abortus vaccine. In every instance clinical improvement exactly paralleled desensitization to the bacterial protein. None of the patients have had remissions within a maximum period of two years after infection. Goats immunized with nitrous acid-treated vaccine yielded a serum which was used to treat three patients. One patient was treated with human hyperimmune serum. In all instances the serum treatment brought about a drop in temperature to normal, and a considerable reduction in hypersensitivity was shown by the skin test. The author believes that this report is justified in view of the fundamental immunologic responses seen in the management of these cases.

Oral Administration of Pollen Extracts—Gatterdam
placed thirteen patients sensitive to the pollen of Bermuda grass
on a 3 per cent Bermuda extract made in a phosphate glycerin
solution The dosage was from 15 to 30 drops orally Nine
patients were treated with ash extract Only one of these took
the treatment pre-seasonally This patient experienced most
gratifying results and did not require any other form of treat-
ment for the relief of asthma Of the other eight only one did
not receive any relief and one experienced only about 60 per
cent relief The other six obtained from 90 to 95 per cent
relief Thirteen patients suffering from the Franserias (rabbit
bush and desert ragweed) took an extract made from these
They all reported from 90 to 100 per cent relief Of the six
who took it seasonally relief was obtained in all but one The
author concludes that oral administration of pollen extracts
has a definite place in hay fever therapy Pre-seasonal treatment
gives the better results however relief may be obtained with
seasonal treatment It is possible to produce a mild gastric
or intestinal mucosal reaction which accounts for the rapid
action similar to that seen with skin testing reactions It
hardly seems possible that digestion and absorption would be
rapid enough Apparently the gastric juice does not have any
detrimental effect on the value of the oral solution

Carboxide for Fumigation—Brown conducted tests in a
relatively air-tight chamber of approximately 2,000 cubic feet
capacity, with the object of determining the minimal lethal
dosage of carboxide gas (ethylene oxide) for fumigation He
recommends the following minimum lethal concentrations per
thousand cubic feet in a relatively air-tight space 5 pounds
for three hours, 3 pounds for six hours, 3 pounds for twelve
hours, 2 pounds for eighteen hours and 2 pounds for twenty-
four hours Carboxide gas is noninflammable and nonexplosive,
is noninjurious to fabrics, furniture or food products, is of about
one thirty-seventh to one sixtieth of the toxicity of hydrocyanic
acid gas for man, and is not prohibitive from the standpoint
of cost

Pancreatic Necrosis—Cracovaner presents three cases of
acute pancreatic necrosis occurring during the administration
of a general anesthetic Only by a careful study of specimens is
it possible to determine the anatomic peculiarities that have a
physiologic significance and constitute an important factor in
the production of this condition He recommends that particu-
lar attention be paid to the comparative size of the pancreatic
ducts of Wirsung and Santorini and to the relation of the
septum separating the common bile duct and the duct of Wirsung
in the ampulla of Vater to the sphincter of Oddi also that a
culture for organisms be made of the bile in the gallbladder
The author suggests the following alternative in those cases in
which facilities are not available for a complete anatomic study
of these structures, both gross and microscopic 1 The gall-
bladder, common and cystic bile ducts, duodenum and pancreas
intact should be removed 2 The pancreas should be cross-
sectioned midway between its middle and its tail end The
common pancreatic duct should be injected with methylenamine,
chloride U S P (methylene blue) by means of a needle and
syringe The injection should be made with the duct of Wirsung
occluded and then with the duct of Santorini occluded The
common bile duct should be injected near its origin 3 The
intact organs should be placed in a 10 per cent solution of
formaldehyde and submitted to the Naval Medical School The
author believes that the most dangerous stage of anesthesia for
the production of acute pancreatic necrosis is during the second
stage of induction and when the patient is regaining conscious-
ness It is then when reverse peristalsis, retching, vomiting,
struggling, and so on are most prevalent

 Granulomatous Ulceration Healed by Antimony Case J F Smith—p 311

Primary Leukosarcoma of the Skin—Goldsmith describes a case with the general characteristics of Sternberg's leukosarcoma. It differs from classic leukosarcoma in that (1) though the tissue tumors were composed mainly of the usual monocytes, the blood leukocytosis was composed predominantly of small lymphocytes, (2) there were no hemorrhages, and (3) the primary tumor originated in the skin and was unusually malignant. The author states that a review of recent work points to the probability that at least the three conditions known as lymphatic leukosis, leukosarcoma and lymphosarcoma are manifestations of the same disease, and that the variations depend on differences in the individual attacked. He believes that his case with its combination of small lymphocytes and monocytes supports this view. He discusses the nature and origin of the monocytes and puts forward a hypothesis as to the pathologic sequence of events.

Celery Itch—Henry observed a form of dermatitis confined to the upper limbs and associated with itching in twenty-two workers preparing celery for canning. The dermatitis commenced as an erythematous, vesicular or papular rash. In the majority of cases the attack was not severe and it was possible for the patient to be transferred to other work while receiving treatment. Nine were cured in one week, six in two weeks, two in three weeks, two in four weeks, and three were not cured until the fifty-third, sixtieth and seventy-eighth day, respectively. The author suggests that the main causative factor is limonene, a hydrocarbon of the terpene series and a constituent of celery oil, water, friction and individual susceptibility playing their respective parts as preparatory causes. The preventive measures adopted consisted of transferring the patient to other work, and the application to the skin of those not affected, of a suitable oil (pure petrolatum) before commencing work.

Purpura—Piney encountered an apparently unknown malady in a boy, aged 17, who had been perfectly well until six days before he saw him, when he vomited. Since then he had felt ill and had vomited after any sort of food. His feces were stated to contain blood on the third day of the illness. The day before he was admitted to the hospital a purpuric rash appeared on his hands and feet. On examination, the rash was seen to be dark reddish purple, some vesicles were the size of a pinhead, whereas others were as big as a shilling. Each spot was slightly raised above the surface and was surrounded by a narrow red areola. The temperature was 96 F and the pulse 120. During the time that the rash was emerging (three weeks), there was a peculiar fecal odor around the patient. The individual spots went through a series of changes, which culminated in the formation of dark purple blebs containing blood-stained fluid. Some of these blebs burst, whereas others disappeared. The fluid obtained by puncturing a bleb was sterile. Two days after admission, the temperature rose to 99.8 F and during the next three weeks it continued to rise in the evening, although it was almost normal in the morning. The blood showed 6,272,000 red corpuscles per cubic millimeter, hemoglobin, 102 per cent, color index 0.8, leukocytes 14,000 per cubic millimeter, neutrophils band forms 12.3 per cent, polymorphonuclears 49.4 per cent, monocytes 21 per cent, and lymphocytes 17.3 per cent. Class I of the Arnett-Cooke count was 47 per cent, class II 49 per cent and class III, 4 per cent. The weighted mean was 1.57. The cytoplasm of all the neutrophilic leukocytes showed toxic changes. The temperature began to settle sixteen days after admission to the hospital, but occasional evening rises occurred for the next two weeks. The patient's general condition improved, but albuminuria was noted. No casts or red cells were found in the urine, and the

patient felt well. The patient was discharged from the hospital eleven weeks after admission, feeling well but still with a trace of albumin in the urine. No abnormalities were present in the blood at the time of discharge. He was alive and well, with only slight albuminuria, ten months later.

 *Radiologic Treatment of Some Cancers of Oropharynx J Maisin L Van Den Wildenberg and H C Vassiliadis—p 479

Radiologic Treatment of Cancers—Maisin and his associates point out that it is possible to cure sarcomas of the tonsils and local epithelial cancers of the oropharynx with external irradiations. The glandular metastases of epithelial cancers are more resistant than the primary lesions. For this reason it is advisable to operate when possible and, later, to irradiate the whole region. The percentage of cures is small. The authors' routine treatment for sarcoma of the tonsils consists of 180 or 200 kilovolts filter of 1 mm of copper, 40 cm distance from the skin and 1500 roentgens on each field. As a rule, they give from 300 to 500 roentgens a day. In epithelial tumors of the oropharynx it is easier to cure the local lesion than the metastases with external radiations. For this reason, when the metastases are operable, it is still preferable to operate by a block dissection of the whole lymphatic system of the neck. It is necessary to dissect both sides and it is advisable to do this in two stages. Even after a good surgical dissection the whole region should be treated to prevent recurrences. The best two methods of external radiation are telecurietherapy and teleroentgenotherapy or the Coutard method. To get good results with the Coutard method it is necessary to use hard rays with the shortest wavelength possible, in order to improve the power of penetration and to increase the selective action on the cancer cells. To obtain such rays one should use at least 200 kilovolts and a filter of 2 mm of copper. With such a filter all the soft rays are absorbed and the lesions of the skin and of the subcutaneous tissue are reduced. The skin in

such a condition can stand 1,500 and even 2,000 roentgens. The distance between the target and the skin is 60 or 70 cm., and the intensity is no higher than 4 milliamperes. The patient should be irradiated at least two hours a day, 500 roentgens being delivered each day. The whole treatment must have a duration of three weeks or even more. During the last two years, in order to improve their roentgenologic results, the authors have used with some success injections of lipoid extract of the brain, the thymus, the bone marrow and the spleen.

Cavernous Angioma of Maxilla—Broderick reports a fatal case of cavernous angioma in the left superior maxilla of a girl aged 11, in whom on the first examination the left side of the face was enlarged and slightly bluish with a pulsating spot over the malar bone, there were four scars, two over the malar bone one near the inner canthus of the eye and one over the region of the facial artery. Examination of the mouth revealed a perfect denture containing twenty-eight noncarious well articulating teeth. The left maxilla was slightly expanded and the two premolar and molar teeth were loose but the gums were firm when the molar teeth were moved a little blood came from the sockets. On the second examination a month and a half later the teeth were looser. The child lost about 8 ounces of blood on two successive nights. This bleeding was apparently coming from the sockets of the molars. Roentgenograms were taken and models of the mouth obtained. The roentgenograms showed extreme absorption of the roots of the first molar tooth and less of the premolar and second molar. The hemorrhage had been controlled by pressure on the teeth. In view of this the external carotid artery had been tied. After the artery had been ligated it was noticed that the pulsation on the cheek had ceased and accordingly the wound was closed. When the first upper molar was

extracted there was an immediate gush of blood, which was checked with difficulty by a finger in the socket. A cotton plug soaked in phenolized resin and tannic acid was then put in the socket and a temporary splint of Stent's composition held over it. While this was firmly held in position there was no hemorrhage, but on the smallest movement it recommenced. It was then decided to open the wound, dissect out the common carotid and clamp it. This was done, and on removal of the splint and plug only a slight trickle of blood came from the socket, therefore it was decided to ligate the artery. This operation was performed and at the same time a piece of the sternomastoid muscle was cut away to serve as a plug to be stitched into place in the sockets. It was then decided to extract the second molar, plug the sockets with muscle and tightly stitch the wound. The moment the second molar was extracted there was a gush of blood, just as violent as the first. This was controlled with pressure with a finger and, although eventually plugs were fitted into each socket and stitched, the patient's heart and respiration ceased and efforts to restore them were unsuccessful.

Treatment of Head Injuries—According to Lee, the first obvious fact in treatment of head injuries is that there is a vast difference in the degree of severity of the injury. The most simple case in which a patient is admitted to the hospital in the recovery stage of a transitory concussion, needs no special therapeutic measures. Such a patient needs only to be put at rest, both mentally and physically. In the more severely affected patient, whose scalp has been injured and about whom a history of unconsciousness lasting five minutes or more is obtained, the scalp wound should not be sutured in a routine manner in the casualty room. In many cases the wound communicates with a compound fracture of the skull and perhaps with the underlying cerebral structures. Unless bleeding has to be controlled, only a first aid dressing should be applied before the patient is admitted to the hospital. The intelligent care of shock is the first and sole duty of the surgeon after the patient's admission. The application of heat and possibly the intravenous and subcutaneous administration of saline solution should be carried out. If a sedative is necessary, morphine should be withheld. When the shock factor is safely combated the presence of a raised intracranial tension should be determined by a lumbar puncture examination with pressure readings. If an increased pressure is present, lumbar drainage should be carried out. Dehydration should be encouraged by limiting the intake of fluids to 900 cc per day for the first few days and less for the weeks following. Mental and physical rest should be enjoined for three or four weeks or longer if necessary, and the associated scalp injuries should be dealt with as soon as the shock can be controlled. The author believes that, during the first twenty-four hours after the occurrence of a severe head injury, operation should not be undertaken except in the rare instance when an extradural hematoma increases so rapidly as to endanger life during that period. After the period of shock is passed, operative treatment may be carried out (1) as the treatment of a compound fracture of the skull, (2) to evacuate a hematoma presenting localizing symptoms, and (3) in severe cases of cerebral contusions which have resisted dehydration treatment. Some weeks or months following the injury operation may be advisable (1) to evacuate a chronic subdural hematoma (2) for the treatment of chronic localized arachnoid adhesions and (3) for the relief of convulsions or for persistent physical symptoms which have resisted long periods of rest.

and dehydration. In patients presenting remote symptoms of head injury, a headache of a general dull discomfort, a localized headache and an intermittent headache of a general bursting character can be recognized.

Uterine Hemorrhage—Hernaman-Johnson states that in order to destroy that particular function of the ovaries which is responsible for the menstrual cycle, a certain minimal quantity of radiation must be passed through them. The rays from the generating tube must first penetrate the overlying tissues. It has been ascertained that 30 per cent of the amount of x-rays necessary to cause a skin reaction is sufficient to produce the required effect on the ovaries of a woman in her fifth decade of life. With the high voltage roentgen apparatus now available from 20 to 30 per cent of the energy falling on the skin reaches the ovary in a patient of average size. It is theoretically possible therefore to sterilize an ovary with a single dose of penetrating x-rays with only temporary damage to the skin. The author uses two fields for each ovary—anterior and posterior. The amount of radiation falling on the skin is less than half of that required to produce an erythema. The two sides are done on consecutive days, and a month later the treatment is repeated with slight modifications. The author has used this technic for many years and has never seen the slightest change in the skin or any constitutional upset.

Bacillus Alcaligenes Infection—Anderson cites two cases which at first appeared to be severe cases of rheumatic fever with cardiac valvular and myocardial lesions associated with painful and swollen joints but not responding to salicylates. Blood cultures were taken and revealed the presence of *Bacillus alcaligenes*. Unfortunately, the organism was not looked for in the stools in the earlier stages of the infection though presumably it emanated from there. The acute infections were relieved by mercurochrome. One patient received one tablespoonful of a 1 per cent solution of mercurochrome in water between meals and the other half an ounce of the solution twice a day.

*Dissociated High Paralysis of Brachial Plexus Following Antiscorpion Serum Therapy A. C. Pacheco e Silva—p. 429

Headaches and Urogenital Disturbances—Valerio states that chronic refractory headaches in males may originate in urogenital disturbances. He reports four cases in which chronic headache which had resisted all customary forms of local and general therapy including surgical and antisiphilitic therapy, yielded to the treatment of existing genital lesions. In the first case the genital lesion was a polyp of the prostatic utricle, in the second a purulent cyst of the prostatic utricle in the third an atrophy of the verumontanum and the prostatic utricle and in the fourth, a papilloma of the verumontanum and ulceration of several glandular orifices of the prostate. Impairment of the sexual function existed in all cases. Cure of the genital lesion in two cases by electrocoagulation and in two cases by fulguration, resulted in disappearance of the headaches together with restitution of the normal sexual function.

Paralysis of Brachial Plexus Following Antiscorpion Serum Therapy—Pacheco e Silva reports the case of a man aged 30 in whom the antiscorpion serum was injected at the level of the interscapular region on the left side. Two days after the injection generalized urticaria, headache, vomiting and diarrhea appeared followed by intense pains in the whole body particularly in the arms and shoulder. Gradually increasing muscular atrophy ended in inability to raise the left arm and difficulty in raising the right arm above the head. On neurologic examination, a pronounced atrophy of the muscles of the supraspinous and subspinous fossae was found, particularly on the left side. The homolateral deltoid and trapezius muscles and the rhomboid muscles also exhibited marked atrophy. On the right side the atrophy affected the inferior trapezius to a greater degree. The patient was unable to raise the left arm and, when he raised the right arm to shoulder level, he exhibited a winged scapula due to atrophy of the serratus major. The spinal fluid contained 5 leukocytes per cubic millimeter. The absence of sensory disturbances in connection with the affected muscles favors a lesion of the spinal nerve roots rather than of the spinal trunk. The patient had never received serum therapy before the injection that produced the paralysis.

*New Method of Operative Treatment of Echinococcus Cysts of Lung P. Valdoni—p. 484

Operative Treatment of Echinococcus Cysts of Lung—Valdoni treated two patients with pleural echinococcus cyst, one with a central suppurating cyst opening into the bronchi and another with two peripheral nonsuppurating cysts. The operative technic consists of extrapleural filling to treat pleural adhesions without opening the pleura, in order to collapse the lung between the cysts and the pleural surface. This collapse easily attained in nonruptured echinococcosis reduces the parenchyma between the cysts and the surface of the lung to an atelectatic stratum with closed bronchi and obliterated vessels so as to avoid during the subsequent open operation the danger of aspiration or introduction of air or liquid into the circulation. The author prefers petrolatum to the sponge or iodoform gauze for filling. At least 400 Gm is used according to Beer's formula. Local anesthesia is produced by 2 cc of a 1 per cent solution of procaine hydrochloride. The first operative stage consists of separating the pleura from the thoracic fascia after which the petrolatum is introduced into the cavity at a temperature of about 38 C (104 F). Exact localization is important in order that the filling may correspond to the projection of the cysts on the thoracic wall under

repeated control of roentgenoscopic examination. In the second stage, twenty days later, the incision is reopened and the petro-lum filling is removed, the cyst is aspirated with a needle and syringe, the syringe is replaced by an adapter furnishing diathermic current to the needle which is used as an electric knife to incise the pulmonary tissue for about 15 cm, the membrane of the cyst is removed with forceps, cleaning of the cystic cavity is completed with a small tampon and a rubber drain is introduced. The extrapleural filling this time is done with strips of iodoform gauze of sufficient amount to keep the cystic cavity collapsed. The wound is sutured except for a small orifice in the lower angle through which protrude the end of a gauze plug and the drainage tube. After from two to three days the tube is removed. The gauze is removed after a week, when communication with the cavity is already closed. The extrapleural filling is repeated with less gauze and continued until roentgen examination shows the complete disappearance of the cavity or its maximum reduction.

Allergic Manifestations Caused by Stimulants—Discussing the allergens in stimulants such as wine, beer, coffee and tobacco, Gutmann states that not the alcohol nor the caffeine but rather other substances contained in the stimulants are the carriers of the allergens. He discusses in detail his studies on beer. Allergic disturbances that have been noted following the drinking of beer are itching, urticaria-like conditions, a feeling of fullness, acidity of the stomach, nausea, diarrhea and colic-like manifestations with severe spasms that sometimes resemble ileus, also migraine, coryza and asthmatic conditions. Since every substance contained in beer may act as an allergen, the offensive factor must be determined. The author describes several test methods that may be employed. In one series of tests he detected a constituent of hops, lupulin, as the allergen, while in other tests he found that yeast was the eliciting factor of severe allergic intestinal spasms. For the prevention of allergic disturbances the author suggests that, if the patient does not want to abstain from beer entirely, it should be determined which beer he tolerates and which not, for some allergic patients are sensitive only to certain beers. He points out that alcohol sometimes exacerbates the allergic condition and that it would be advisable to recommend to allergic patients an alcohol free beer, which moreover has the advantage that it is not made with yeast and therefore could be recommended to those persons who have a hypersusceptibility to yeast.

*New Hereditary Blood Disease Constitutional Thrombopathy E A von Willebrand and R Jürgens—p 453
Nocturia A Jores—p 484

Constitutional Thrombopathy—Bleeding disease without thrombopenia was observed by von Willebrand in a group of families in Finland, and the studies on the members of these families, carried on by him and by Jürgens, are reported in detail. The disturbance, designated as constitutional thrombopathy, is familial and hereditary, and the genealogical trees indicate that it is transmitted by the dominant gene. It seems that the dominance can sometimes be suppressed but whether the gene is found in an autosome or in an accessory chromosome has not been determined. The latter assumption is supported by the occurrence of two types of bleeders among the women and of only one type among the men and also by the fact that the greater number of diseased women were detected in the two consanguineous marriages. However the fact that a

healthy father had a son who was a bleeder, and the records of another family contradict this hypothesis. Occasionally the disorder becomes manifest during the nursing age, while in other families it does not become evident until the period of puberty, and in later life, particularly after the climacteric, the bleeding tendency frequently decreases again. Both sexes are subject to the disturbance, but in women it is generally more severe than in men. The hemorrhages may occur in the skin or in the mucous membranes, the site of predilection being the nose, but hemorrhages from the gums are also comparatively frequent and even the female genitalia, the gastro-intestinal tract and the urinary tract may become involved, and there is prolonged bleeding after injuries. The majority of the patients are of the asthenic type and appear nervous. Inbreeding seems to play an important part in the pathogenesis. The white and red blood pictures reveal no essential changes. The number and shape of the blood platelets are normal, but there is an increase in giant platelets. The agglutination of the platelets is retarded. The "thrombosis time," determined in the capillary thrombometer, is prolonged, but coagulation and retraction are normal. The bleeding time is greatly prolonged, which is considered especially characteristic for constitutional thrombopathy. The vascular factor is of minor importance. The treatment is mostly symptomatic and follows largely the general rules that govern the therapy of hemorrhagic diatheses. In severe cases, blood transfusion is resorted to.

Klinische Wochenschrift, Berlin

12 1273 1312 (Aug 19) 1933 Partial Index

*Chronic Intermittent Gastric Volvulus Berta Asehner—p 1283
Iodine Metabolism in Diseases of Thyroid L Scheffer—p 1285
Bronchial Asthma and Influenza K Hajos—p 1287

Serologic Diagnosis of Tuberculosis—Favorable results obtained by others with the complement fixation test that uses the antigen of Witebsky, Klingenstein and Kuhn induced Beck and Schedtler to employ this test and, in order to check the results of the complement fixation test by a simple seroreaction, they performed the precipitation test of Lehmann-Facijs-Loeschke. They made these tests on 151 patients with tuberculosis and in 209 control cases. They state that the complement fixation test with the antigen of Witebsky-Klingenstein-Kuhn gives satisfactory results as regards the specificity and the constancy of its outcome. With 70.2 per cent of positive reactions in patients with pulmonary tuberculosis and with 35.5 per cent of positive reactions in extrapulmonary tuberculosis, the inclusiveness obtained by the authors was somewhat less than that reported by other investigators. No definite conclusions have been reached as yet about the prognostic significance of the test. The precipitation reaction according to Lehmann-Facijs-Loeschke gave a higher percentage of positive results than did the complement fixation test in pulmonary as well as in extrapulmonary tuberculosis, but in specificity it was not equal to the complement fixation test. The authors recommend that both tests should be further investigated on a large scale.

Chronic Intermittent Gastric Volvulus—Aschmer describes the history of a girl who asked medical advice on account of dyspeptic disturbances. After eating, she had a feeling of tension in the epigastrium and there were frequent eructations. She also had poor appetite and was troubled with constipation. The family history disclosed that the father and two brothers of the girl had intestinal ulcers. Examination of the gastric contents did not favor an ulcer but made an anacid gastritis more probable. The roentgen examination revealed a partial volvulus of the stomach. A roentgenoscopy three weeks later showed that the gastric volvulus had disappeared. Later the disturbances reappeared after intervals of several weeks or months, which indicates that the volvulus was of the chronic intermittent type. The symptoms being comparatively mild there was no necessity for an operation. In this case congenital anomalies were the cause and were evidenced by congenital

abnormalities in the mesogastrium and particularly by an abnormal length of the hepatoduodenal ligament. The author considers these mesenteric anomalies the necessary predisposition for the development of idiopathic gastric volvulus. She states that, in some instances, it may be possible to assume the existence of a chronic intermittent volvulus of the stomach before the roentgenologic examination.

Nutritional Disturbances Following Gastric Resection—In nutritional disturbances that developed several months after gastric resection (Billroth II), Dibold observed various changes in the remaining stomach, the small intestine, the large intestine and the pancreas. Discussing the diagnosis of these changes, he points out that the anamnesis, the clinical aspects, and examination of the blood, the gastric juice, the urine and the stool frequently allowed an exact anatomic and functional diagnosis to be made, especially if all the changes were considered together. Roentgenologic examination was also necessary in some cases, but the clinical observation could never be replaced by roentgen examination, because even in cases presenting large anatomic changes clinical observation was necessary for the interpretation of the roentgen picture. The author calls attention to the hypoglycemic attacks that may develop in persons who have undergone resection of the stomach following administration of carbohydrates after injection of insulin (even of comparatively small quantities) and after simultaneous administration of carbohydrates and insulin. Hypoglycemic attacks, as observed in these patients, are exhibited with the same severity only in diabetic patients with hypersusceptibility to insulin. The author emphasizes that the possibility of hypoglycemic changes after gastric resection should be kept in mind, since, if this condition is overlooked, valuable time may be lost for treatment. The dietary treatments for the various conditions are described and evaluated.

Borderline Ray Therapy in Internal Diseases—Bucky's borderline rays were employed by Last in the treatment of various internal disorders, particularly those of a functional nature. He points out that since the skin has been found important for a number of vital functions, the general therapy by means of borderline rays, that is, the therapeutic action of rays through the skin can no longer be questioned. His report is based on observations made in the course of several years. He found the borderline rays helpful particularly in menopausal disturbances. Of 174 cases, only 52 per cent were not favorably influenced. However, it appears that the efficacy of these rays in menopausal disorders is dependent on the presence of remnants of ovarian activity, because in the menopausal disturbances developing after the surgical removal of both ovaries the general therapy with borderline rays produced only temporary improvement. The author tried this therapy also in some forms of hyperthyroidism and noted a considerable reduction in the basal metabolic rates. In disturbances of the sympathetic nervous system, especially those of convalescence after influenza, this general therapy was found to counteract the predominating vasomotor disorders and the weakening sweats. It proved effective in eight out of twenty patients with nervous bronchial asthma, and the vasoneurotic component of anginous attacks likewise yielded to this treatment. The author also obtained favorable results with the borderline ray treatment of gastric and duodenal ulcer already recommended by Bucky. The aim was of course only to counteract the pains by reducing the spastic condition of the gastric muscles as the healing of the anatomic lesion could hardly be expected from the irradiation. The author hopes that the favorable results obtained by him will stimulate further work with this form of ray therapy.

Simplification of Aschheim-Zondek Reaction—now says that the original method of Zondek-Aschheim disadvantage of employing only female white mice, a that makes it necessary to keep large numbers of m the females used in the test are withdrawn from pro The author employed the modification recommended by Hinglais and Simonnet, who use male instead of female. One of two male mice of the same litter and of the same is given, for five or six successive days, injections of 0.5 to 1 cc of the urine that is to be tested. The second mouse serves as control. Both mice are killed two hours after the first has received the last injection. The of the accessory sex glands and of the glans penis are compared. The accessory sex glands located immediately the urinary bladder become considerably enlarged under influence of urine from a pregnant woman. The increase the size and weight of the glans penis is not so reliable indicator, for its size shows normally considerable fluctuation and consequently the author gives more attention to the change in the accessory sex glands. He tested the urine of six persons, most of them (thirty-seven) pregnant women, the others had amenorrhea, fibromyoma, prolapse of the adnexa, ovarian cysts, or cancer of the uterus, and the persons were men. Positive reactions were obtained in the case of pregnant women and of patients with cancer of the uterus. Thus the results are just as reliable as obtained with the original method. However, certain grat that can be detected with the original Aschheim-Zondek are not possible with the simplified procedure, and the original method still retains its significance for research, but for routine pregnancy tests, the author considers the modified more practical and more economical.

—p 1254

Submammary Temperature—Zelc and Djokic call attention to the fact that a normally lactating breast has a higher temperature than mammary glands with a deficient secretory function and they cite other observers who have noted this. The submammary temperature is estimated in comparison with the axillary and the rectal or sublingual. The authors performed such tests on nonpregnant pregnant and lactating women and found that during the first half of the pregnancy the submammary temperature is the same as somewhat lower than the axillary but that during the second half it is higher than the axillary temperature and approaches

the rectal or the sublingual During the puerperium and during lactation, monothermia develops, that is, the submammary and the rectal or sublingual temperatures become equalized It was also noted that the act of nursing does not cause changes in the submammary temperature If the two breasts are of the same development, their temperature either is the same or differs only slightly The authors think that measuring of the temperature of the mammary glands is the simplest method for the determination of the functional capacity of the mammary glands The nearer the submammary temperature comes to the rectal or to the sublingual, the more favorable are the prospects for the lactating capacity If at the beginning of lactation the submammary temperature is higher than the axillary and approaches the rectal or the sublingual, the mother should be encouraged to nurse her child although the milk supply may at first seem too small In many of these cases the hypogalactia is the result of insufficient evacuation of the mammary glands, and the mother should be told to see to it that the breasts are completely emptied However, in cases in which the rectal or the sublingual temperatures are constantly considerably higher (more than 1 degree C, or 18 degrees F) than the submammary temperature, the lactating activity is slight, and even artificial evacuation of the breasts does not stimulate lactation in these cases But if the submammary temperature has a tendency to increase so as to become nearly equal to the rectal temperature, the lactation process has a favorable prognosis

Histamine Treatment of Muscular and Articular Disturbances—Faber employed histamine treatment in acute and chronic myalgias, sciatic neuralgias, acute and chronic arthralgias, and posttraumatic or postoperative local circulatory disturbances In painful conditions limited to a small area, he employed Deutsch's original method of histamine therapy, that is, he gave intracutaneous injections of from 0.1 to 0.3 cc. of a 1:1,000 solution of histamine In order to increase the efficacy of these intracutaneous injections, the author applied a galvanic current of from 4 to 7 milliamperes for about five minutes Of the twenty-two patients treated in this manner, eighteen were entirely free from complaints after the first treatment and two others were considerably improved However, he emphasizes that the treatment is suitable only for cases in which the painfulness is limited to a small area The majority of his patients were treated with a histamine ointment At first the application of the ointment was combined with iontophoresis, but later he resorted to iontophoresis only in those cases in which scarification was contraindicated his usual method then consisting of incision following scarification with a wheal needle or Ponndorf's scarifier He asserts that this simple method gave the best results The treatment was generally well tolerated, and the author considers neurasthenia with vasolability and allergy the only contraindications He states that the results of histamine treatment were not convincing in chronic arthropathies and in sciatic disturbances, but that in acute and chronic myalgias, acute arthralgias, periostalgias and postoperative and posttraumatic circulatory disturbances of the extremities he obtained excellent results

Changing Character of Successive Metastases in Myosarcoma of Uterus N Christophorakos—p 1935
Treatment of Inoperable Prolapse A I Scherbak—p 1940

Intraparenchymal Vaccination in Puerperal Sepsis—Spirito employs a polyvalent vaccine containing streptococci, staphylococci, gonococci and colon bacilli He makes the injection by means of a Pravaz syringe which enables him to introduce the vaccine deep into the soft parenchyma of the vaginal part of the cervix The injection is repeated every third day and the single dose is usually one third cubic centimeter Each injection is followed by a general reaction characterized by an increase in temperature The intensity of the reactions decreases in the successive injections and the treat-

ment is continued until there is no longer a reaction According to the degree of the reaction following the first injection, the doses of the subsequent injections either remain the same or are somewhat increased The author emphasizes that the results of the treatment are the more favorable the earlier the treatment is begun The author states that the vaccine injected into the uterus is more effective than the intramuscularly administered vaccine because it enters the organism by the same route as did the pathogenic organisms and thus finds more favorable conditions for its entry and absorption

Changing Character of Metastases in Myosarcoma—Christophorakos relates the history of a woman, aged 58, in whom the uterus and the adnexa were removed on account of uterine hemorrhages and of myoma The microscopic examination of the specimen revealed myofibroma with areas of deficient maturity, and sarcoma was suspected In the course of eighteen months a large tumor developed in the lower part of the abdomen The histologic examination of the extirpated tumor disclosed an edematous fibroma, and there were no indications of malignant degeneration Ten months later a new operation became necessary because a tumor of the size of two fists had developed This one proved to be a fibromyoma and again there were no signs of malignant degeneration Six months after this intervention a fourth operation became necessary, and this time the examination disclosed a polymorphocellular sarcoma that in some portions showed the structure of a fibromyoma New metastases and cachexia followed this intervention and the patient died two years later The unique character of this case, in which the removal of a sarcoma was followed by two relapses of benign character and in which only the third relapse showed a reversion to malignity, was the reason for reporting this case

Treatment of Inoperable Prolapse—Scherbak admits that the operative treatment of prolapse of the genitalia is the most effective but points out that there are some patients who decline a surgical intervention or are unsuitable for such treatment, and in these pessary treatment has to be resorted to He shows that he obtained good results with a modification of Rosenfeld's funnel pessary or of Menge's pessary He observed that these funnel pessaries function properly only if the total height of the pessary is at least from 1 to 1.5 cm greater than the diameter of the cup portion, so that the end of the stem protrudes a little from the vaginal opening He explains the mechanism of action of this pessary and states that at present it is giving good results in the treatment of twelve women between the ages of 60 and 85, who for various reasons could not be operated on, and that all feel greatly relieved

Heyle's Operation for Hydrocephalus I E Kartava—p 96

Heyle's Operation for Hydrocephalus—Kartava calls attention to the fact that attempts at surgical treatment of hydrocephalus have been unsuccessful thus far He performed the Heyle operation which consists of an anastomosis of the dura mater to the ureter, in a patient aged 16 months Cerebrospinal puncture established it to be an instance of a communicating hydrocephalus The head was unusually large presenting a circumference of 91 cm A one stage operation was carried out under ether anesthesia The left kidney was removed and the ureter was dissected out for a distance of about 6 cm Next, a laminectomy involving the third and fourth lumbar vertebrae was performed The freed ureter was placed in a muscular tunnel made by a longitudinal sectioning of the long muscles

of the spine. The pelvis of the kidney was sutured to the dura mater, the latter incised, and an anastomosis between the two carried out. The immediate postoperative course was distinguished by an almost continuous micturition and a marked improvement in all the symptoms. On the fourteenth day the circumference of the head diminished by 13 cm. The child died rather suddenly on the eighteenth day of a cause that could not be ascertained. The author concludes on the basis of his own and twelve other cases in the Russian literature that the operation proposed by Heyle in 1925 accomplishes an effective drainage of the ventricles, that the patients tolerate the operation quite well, and that the immediate results are quite gratifying.

 *Bilateral Inguinal Hernia with Unusual Contents Case A. A. Busalov—p. 478

Traumatic Injury to Kidney—Kupershiyak states that traumatic injuries of the kidneys are rather common and occur more frequently as a result of traffic accidents than in the course of industrial occupations. Intrapelvic tension is not of great moment, since under normal conditions the renal pelvis is not distended. The twelfth rib is the most important immediate traumatizing factor. Trauma to renal tissue is to be considered as one of the many causes of inflammatory and obstructive lesions as well as of urolithiasis. The treatment of renal trauma should be conservative. Operative intervention is indicated only in the presence of grave symptoms. Its aim, however, is to preserve renal tissue as far as is possible. Small tears are to be sutured, tearing off of a pole is treated by a wedge shaped resection and suture. Nephrectomy is justified only when these operations cannot be carried out.

Bilateral Inguinal Hernia with Unusual Contents—Busalov's patient was a woman, aged 36, presenting a bilateral inguinal hernia. She had a well developed body, fully developed breasts and a typical female pelvis, but no growth of pubic hair. The large as well as the minor pudic lips were poorly developed, but the clitoris was well developed. On vaginal examination, no evidence of cervix, uterus or adnexa was found. The vagina ended in a blind sac. At operation the exposed right inguinal hernial sac contained a structure which was identified as a rudimentary uterine horn. Adherent to its lateral celae aspect was a structure which on inspection resembled a testicle. From the opposite lateral surface of the horn ran what appeared to be the broad ligament containing the round ligament. The latter pierced the hernial sac and ended in the tissues of the labium majus. On the supposition that a state of true hermaphroditism existed here, the author removed the testicle with the uterine horn. Exposure of the left inguinal canal revealed an identical picture. The hernial sac likewise contained a uterine horn with a sexual gland attached to it. The latter was separated from the horn and replaced on its pedicle into the peritoneal cavity. The horn was resected. Histologic study of the sex gland removed from the right side proved it to be a testicle. The author concludes that the case is an instance of bilateral hermaphroditism, an anomaly of inclusion of male sexual glands in a female subject. The hormone products of these glands were apparently neutralized to a considerable extent by the activity of the patient's female hormone system. The absence of a normal uterus is explained on the basis of failure of development of the müllerian ducts. These were completed in their caudal end but the proximal ends failed to unite each giving rise to a uterine horn. The incomplete short round ligament pulled the uterine horns to the inguinal region. The effect of constant pull of the elastic muscle fibers on the lateral fossa resulted in the formation of a hernia. The author could not find a similar case in the literature available to him.

Electrocoagulation in Hypertrophy of Prostate E. Groth Petersen—p. 805

Electrocoagulation in Hypertrophy of Prostate—Groth-Petersen says that improvement in the results of treatment of prostatic hypertrophy depends mainly on more prostatectomies in the favorable stage and reduction of the operative mortality by strict selection of operable cases. The stricter this choice, the greater the number of patients referred for palliative treatment. For these patients endo urethral electrocoagulation seems to be of great value and preferable to cystostomy or catheter life. The treatment is well borne and the immediate results show clinical recovery in a large number of cases. Little is as yet known as to the permanence of recovery.

*Epidemiology and Etiology of Inguinal Lymphogranuloma S. Hellerstrom and E. Wassen—p. 545

Inguinal Lymphogranuloma—Hellerstrom's discussion of the epidemiology of this disease is based on the literature and on answers to questionnaires in 1,636 cases of inguinal lymphogranuloma and 215 of esthiomene. From his review of recent experimental observations on the etiology of inguinal lymphogranuloma, Wassen concludes that it is an infectious disease of distinct entity, which is practically 100 per cent transferable to monkeys and to which even mice are susceptible. The susceptibility of guinea-pigs to the infection has not been established. The virus, of marked lymphotropic nature, is in all probability invisible and filtrable. The virus can be demonstrated in the regional lymph nodes in man shortly after infection and under certain conditions may be found after several years.

PROSTATIC RESECTION AND SURGICAL PROSTATECTOMY

COMPARISON OF IMMEDIATE RESULTS IN TWO
EQUAL CONSECUTIVE SERIES OF CASES

CHAIRMAN'S ADDRESS

N G ALCOCK, MD
IOWA CITY

A year ago this month at the American Urological Association meeting at Toronto I summarized my first ten months' experience with transurethral prostatic resection, reporting 175 cases. During the past year I have continued to handle prostatic cases by this method and the total number is now considerably over 500. The added experience gives me no reason to retract any of the statements that I made in my original report or to minimize the dangers and difficulties to which I then called attention. Many of the things that were expressed as opinions have now become quite firm convictions and I believe that I can now state that so far as I myself am concerned I will continue to do prostatic resections rather than surgical prostatectomies until some better method is at hand.

As experience has accumulated, troubles and tribulations have become very much less, the time of resection has very much diminished, the amount of tissue removed has increased, the course of the patients has become much more smooth and the results have been more certain and much more satisfactory.

The methods that I employ of handling resection patients have changed in only a few respects. One innovation is that I am now having air cystograms taken as a routine, and urethrograms with jelly made of iodized oil, before and after resection, and this procedure is invaluable. Another change is that more and more of the operations are being purposely done in two sittings rather than one and I think that there are very definite advantages in so doing. In many cases in which it has been definitely planned to do the operation in two sittings, the functional result following the first resection has been so satisfactory that a second resection was not necessary. The indication for the second resection is based largely on the functional result and the postoperative cysto-urethrogram. Another point in this connection that should be stressed is the fact that the second resection is always easier to do than the first and the tissue can be removed in larger quantities and more rapidly than at the first sitting.

In order to evaluate the procedure of resection I am making a comparison of the results obtained in 400 consecutive prostatectomies that I have done. It is extremely difficult in any type of prostatic surgery to

compare the results of one man with the results of another, as many of the factors will be unequal. For instance, if the bulk of one man's patients is made up of charity cases, his mortality rate will be bound to be comparatively high, while if his cases are all private patients his mortality rate should be only a fraction of that of the other man. Then, too, urologists can roughly be divided into two groups on the basis of indication for prostatectomy. One group advocates the early removal of the prostate while the other and more conservative group believes it should not be attacked surgically until it is producing definite damage. In the case of the first group the mortality rate will be low but prostatectomies will probably be done that time might have proved unnecessary, while with the second group the mortality rate will be higher and probably some of the fatal results would not have been fatal had the patient dropped into the hands of the first group. But these more conservative men will, of course, do no unnecessary prostatectomies. The thing balances itself quite well and I have no quarrel with either group, but I belong to the second. Then, too, it is quite unfortunate, yet it is a definite fact, that there are many and quite elastic methods of estimating mortality in prostatectomy.

Resections are done in many cases in which a prostatectomy would not be indicated and I refer here to bars, contractures, small median lobes, and so-called prophylactic prostatectomies. It would, of course, be unfair to have a series of resections diluted by these excellent risk cases and then compare those results with the results of real prostatectomies. In order, therefore, to eliminate this inequality I have not included in the 400 consecutive cases of resection any bars, contractures or small median lobes, or any cases in which I would not have formerly recommended a surgical prostatectomy. In other words, in every one of these 400 resections I would have formerly recommended a prostatectomy. Therefore here are two groups of cases equal in number, having the same geographic distribution and coming from the same strata of life, handled in the same hospital by the same medical, surgical and nursing staffs, all factors being as nearly alike as possible except the method of operation. I do not know how a more fair comparison could be made. What unavoidable inequalities there are I think are entirely in favor of prostatectomy.

The first question that arises is Which cases can be done by the resection method and which cases must be left for surgical prostatectomy? This is a very difficult question to answer and it is largely a personal matter. Ninety per cent of the result of resection depends on the man who is doing it and I think the same thing will apply in the answer to this question. I am convinced that with certain very limited reservations the size of the gland does not determine the

question of resection or prostatectomy. Of course, if the instrument cannot be introduced into the bladder a resection cannot be done. There were four such cases. There is, however, one very small group of cases in which I have found that it is quite useless for me to do a resection. Those are the cases in which the enlargement is considerable and is confined to the space between the two sphincter muscles. I have had four such cases. The easiest cases to do by resection, and the ones with the best assurance of good functional results, are those in which the obstruction is due largely, or almost entirely, to a very discrete and almost wholly intravesical median lobe, and it does not make much difference as to what the size of this lobe may be. The most difficult cases to do are those in which large amounts of intra-urethral lateral lobes must be removed.

Only 4 per cent of the prostatectomies were carcinomas. This small percentage, of course, was due to the fact that prostatectomies were not being done in carcinoma cases, whereas, resections on malignant glands have been done as a routine and the percentage in resections is 19.

TABLE 1—General Summary

	Prostatectomies		Resections	
	Number	Per Cent	Number	Per Cent
Hypertrophies	375	90.0	324	81.0
Carcinomas	25	4.0	76	19.0
Age				
90 to 100	0	0.0	1	0
80 to 90	15	3.7	25	6.2
70 to 80	136	34.0	221	58.8
60 to 70	204	51.0	127	31.7
50 to 60	41	10.2	12	3.0
40 to 50	4	1.0	0	0.0
Over 70	151	37.7	261	65.2
Under 70	249	62.3	139	34.8
Average age		66.3		72.1

The average age of the prostatectomy patients was 66.3, while that of the resection patients was 72.1 years. The average age of the last 200 resection patients was something over 73 years. Only 27.7 per cent of the prostatectomy patients were over 70 years of age, while 65 per cent of the resection patients were over 70. Ten per cent of the prostatectomy patients were between 50 and 60, while only 3 per cent of the resection patients were in that age group. This means that resections were being done in many cases in which I formerly would not have had the courage to do a prostatectomy, and looking at the group as a whole I believe that I can say with more conviction than I did a year ago that at least 20 per cent of the resection cases were such bad risks that I never would have attempted a prostatectomy.

HOSPITALIZATION

Approximately 90 per cent of the prostatectomies were done by the two-step method. It was the routine procedure to require at least ten days of indwelling urethral catheter drainage previous to cystostomy and in only three of the cases was that not observed. The average preoperative hospital days for the prostatectomies was forty-three and the total average hospital days for the 400 prostatectomy patients was seventy-one days. It was customary also to send the patient home following the cystostomy for a period varying from three weeks to several months. The average interval between the two operations was seventy-seven days. I mention these facts to show that the importance of preoperative treatment was not minimized and the apparently high mortality rate certainly cannot be explained on the basis of lack of preoperative treatment

or the care with which that was carried out. The average preoperative treatment for the 400 resection cases has been eight and one-half days and the average postoperative hospitalization time has been nine days, making a total of seventeen and one-half days as against seventy-one days for the prostatectomy cases or a saving of over fifty days per patient. When it is realized that it costs approximately \$5 for each hospital day it can be readily estimated what the tremendous saving has been in more than 500 cases. It means a saving of approximately \$250 per patient. Multiply that by 500 and the sum is not small. The decrease in the amount of gauze and cotton used in the service since resection was taken up amounts to about \$7,200 a year. The saving in Pezzer catheters alone in one year was nearly \$600. In general it can be said that a bed that previously cared for one prostate patient is now caring for four. These are items that are of tremendous importance in the care of the sick, particularly during times like these.

There is also great saving in the nursing care and it would be very difficult to estimate that in dollars and cents. It is the exceptional private patient now who needs a private nurse and it was the rule to have two private nurses on each private prostatectomy patient for at least six days. It is not uncommon for a private patient to have a total hospital bill of \$100 or slightly less including the cost of his preoperative and postoperative roentgenograms and \$25 for the use of the operating room.

HEMORRHAGE

What I said about hemorrhage in resection a year ago still holds. I feel convinced that any uncontrollable hemorrhage at the time of operation is the fault of the operator and not the method. The amount of blood lost during the operation should be and is insignificant. I will not deny that there will be now and then a very rare case in which one will have a hemorrhage at operation that one cannot control and it may be necessary to open the bladder. That is true of any surgical procedure. In this resection work no such case, fortunately has occurred. No bladder has been opened to control hemorrhage and no bag or other device has been used in any case for the control of hemorrhage. The hemorrhage during the first week or so following resection should also be and is insignificant and easily under control. The loss of blood during these two periods in resection is only a small fraction of what it is in prostatectomy. In no one of these 400 resection cases has hemorrhage had anything to do with a death or with the course of the patient.

Late hemorrhage frequently occurs in resection. The vast majority of these patients have been heard from a month after they have gone home and fully 70 per cent of them have reported some terminal hematuria during the third, fourth and fifth weeks. In only eight cases has this hematuria been of any magnitude. Seven of these eight patients have returned to the hospital. The one who did not return had a hemorrhage that lasted twenty-four hours. Three of the seven who returned had stopped bleeding by the time they got to the hospital. Of the other three, one had no further hemorrhage after the clots were washed out of the bladder. Of the other two in one—and this was the most severe that I have ever had and was the only one in whom the hemorrhage was great enough to increase the pulse rate—the hemorrhage was coming from a spurter in the anterior cleft between the two lateral lobes and no cuts had been made in this area and the

patient gave a history of having had gross hematuria previous to resection. In the last case the hemorrhage was coming from an area from which apparently a slough had just been released and was easily controlled by fulguration. In the prostatectomy cases there were seven late hemorrhages, in two this hemorrhage was the all important factor in the deaths of the patients and in several of the prostatectomies I am quite positive that the loss of blood during the first few days was at least an important contributing factor in their demise.

The cause of the late bleeding in resection has been attributed to the sloughing of the tissue. Undoubtedly in some cases this is true, but I believe that more of the hemorrhages come from the granulation tissue that is formed over the area of resection. I have had an opportunity to use the cystoscope in several cases in which there had been bleeding and in many of them there was no evidence of any slough.

Since September, 1931, no cystostomies have been done in resection cases as a step in the preoperative treatment. Two cystostomies, however, have been done in order to control bleeding that the patient had when he was admitted to the hospital. In one of these cases it seemed necessary to do a prostatectomy in order to control the most violent hemorrhage that I have ever seen in such a case. In the other case a resection was later done. Several patients have been admitted and resections performed on whom cystostomies had been done elsewhere previous to admission to the University Hospital. Two other patients who came in with rather violent preoperative hemorrhage had their hemorrhage completely and immediately controlled by immediate resection.

INFECTION

Infection, I believe, is the most serious, the most troublesome, and probably the most common complication following resection and is at the present time our biggest problem. The explanation, it seems to me, is to be found in the necrosis that follows in the wake of the resection. It is true that the film of coagulated tissue is very thin, but the depth of the necrosis extends far beyond the zone of coagulation. This necrosis in part is probably due to the heat produced in the tissue, as has been shown by Caulk, but I am quite sure that thrombosis also plays a very important role. The extent of this necrosis varies greatly in different patients and is entirely absent in many of them. It furnishes a fertile field in the presence of urine for infection and I believe, is the explanation of it. This infection with sepsis and uremia has been by far the most common cause of death in our series of resection, but even though it has been the most common cause it has not killed as many patients as infection did in the 400 cases of prostatectomy.

Encrusted cystitis occurred in three of the early cases in which resection was done. One cleared up by itself and the other two cleared after the encrusted areas had been cut away with the resectoscope. The same condition was noted in two of the prostatectomy cases.

Frequency of urination following resection is one of the most troublesome things about the entire procedure and as I see it there is really nothing in prostatectomy with which to compare it. In practically all the cases of resection there is a fairly well marked frequency immediately after the indwelling catheter has been removed. The rule is that as the days go by this frequency decreases but in a fair percentage of the earlier cases it was quite persistent and in a few of them

seemed to be almost permanent. The occurrence of this persistent symptom decreased as our experience grew and it is no longer a troublesome manifestation. Several of the early patients in whom it was manifest have been relieved by a second resection. In one case in which the frequency amounted to a nocturia of from eight to twelve times for a period of four months it was immediately and completely relieved by the removal of a piece of tissue that had been left in the bladder at the time of resection.

I do not mean to minimize the importance of this complication but I do believe that as resections are done better it will be found that the symptom does not occur. While it is troublesome it is not serious.

RESIDUAL URINE

Practically all the resection cases have shown varying amounts of residual urine immediately following the removal of the indwelling catheter. As a rule, this rapidly decreases in amount as the days go by, and if it does not disappear it is an indication for a second

TABLE 2—Mortality

	Prostatectomies		Resections	
	Number	Per Cent	Number	Per Cent
Total	97	24.2	26	6.5
Benign	82	21.9	18	5.5
Carcinomas	15	60.0	8	10.0
Cystostomy	67			
Prostatectomies	30	9.0		
Average age		68		74.3
80 to 90 years	6	40.0	3	12.0
70 to 80 years	46	34.0	17	7.2
60 to 70 years	38	18.0	6	4.8
50 to 60 years	7	17.0	0	0.0
1st 50	13	26.0	11	22.0
2d 50	6	12.0	4	8.0
3d 50	12	24.0	3	6.0
4th 50	10	20.0	1	2.0
5th 50	12	24.0	6	12.0
6th 50	16	32.0	0	0.0
7th 50	13	26.0	1	2.0
8th 50	15	30.0	0	0.0
Last 300	78	26.0	11	3.6
Last 200	56	28.0	7	3.5
Last 100	28	28.0	1	1.0

resection unless the cysto-urethrogram shows a complete absence of obstruction. I do not consider the presence of residual urine in the first week or ten days as anything at all serious.

This cannot be compared with anything in prostatectomy for the simple reason that during the corresponding period following the surgical removal of the gland there is always bladder drainage. I have no idea that if a prostatectomy patient had no means of getting rid of the urine except through the urethra he would have considerable residual urine if not retention, during the first two weeks following prostatectomy.

EPIDIDYMITIS

There has been no difference in the occurrence of epididymitis in resection and in prostatectomy and I believe that it is wise to do vasectomies as a routine, although I do not always do it.

MORTALITY

The virtues of different surgical procedures on the prostate have been largely determined on the basis of mortality rate. I do not believe that this is entirely sound but it is the custom just the same. In the 400 prostatectomies ninety-seven deaths occurred with a

mortality rate of 24.2 per cent. Of these ninety-seven deaths it is important to note that sixty-seven, or 70 per cent, occurred between the first and second operation. Thirty of the deaths followed prostatectomy. If the sixty-seven cystostomy deaths were not counted in the mortality the rate would drop from 24 per cent to 9 per cent. If the fifteen carcinoma deaths also are eliminated, the mortality rate would be less than 5 per cent. This illustrates how easy it is to change the rate by different methods of estimation. On the other hand, in the 400 resection cases there were twenty-six deaths, giving a total mortality of 6.5 per cent. Of these twenty-six deaths, fifteen occurred in the first 100 cases, leaving eleven in the last 300, and during the last 275 resections there have been two deaths with a mortality rate of less than 1 per cent. A careful review of the table of deaths shows a consistent decrease in the mortality rate for resection, while that in prostatectomy has been constant. A mortality rate of less than 1 per cent is entirely too good to be true and if I can keep the death rate below 5 per cent in the patients that I am compelled to handle I will be perfectly satisfied.

TRANSURETHRAL PROSTATIC RESECTION

CLINICAL CONSIDERATION, WITH ANALYSIS AND STUDIES OF RESULTS

LEON HERMAN, M.D.
AND
LLOYD B. GREENE, M.D.
PHILADELPHIA

We have aspired to follow intelligently the progress of perurethral prostatic surgery. With no original technic to champion, and having distaste for clinical experimentation, we have sought to apply the various procedures with an open minded caution becoming to beginners. With others, we await a comprehensive analysis of results obtainable by resectoscopy, the ultimate fate of which must be founded on broad clinical experience rather than on the views of a few protagonists of one method or another. It would seem desirable to describe for the guidance of beginners some heavy weather that may be encountered, even by the cautious navigator, on the seas of prostatic resection. We venture, for these reasons, to present an analysis of our limited personal experience.

TECHNIC

In scientific surgery, mechanics should be the means to an end and not as we fear is sometimes true of resectoscopy, the end itself. This suspicion naturally arises when, as now seems to be the fashion, the criterion of success is held to be routine application of the method. As it is a difficult craft, differences in results are to be expected, and one should not question, therefore, claims of extraordinary success with methods which we have used and found wanting. It is a delightful inevitability that the technic warmly advocated by one may fail in the hands of another.

Experience with more than 100 operations for bar prostatism by the original Wappler-Collings technic taught us the destructive limitations of that method and

the need for a more effective electrosurgical means of excising obstructive prostatic tissue. Familiarity with the foregoing technic explains too our preference for the Stern-McCarthy resectoscope, with which all of the operations in this series have been performed. We prefer the larger instrument (size 28 F). This is said to be more productive of traumatic bleeding but this has not been true in our experience. Traumatic hemorrhage especially that coming from the roof of the urethra may be most annoying but is rarely serious. In one case, profuse instrumental bleeding coming from the floor of the urethra deeply placed between large lateral lobes was controlled with difficulty and only after the overhanging tissue had been excised. In similar cases the beginner would do well to defer operation. Difficulty was encountered in distending the bladder, owing to leakage around the tube in two of eight cases in which preliminary cystostomy was employed.

In two instances, incisional hemorrhage proved quite difficult to control, but in neither case was the operation discontinued. On the whole the technical difficulties have been negligible, which is attributable perhaps to adequate experience with other perurethral operations for prostatism and to the fact that the technic of revision was acquired, as it should be, in operations on small obstructions.

We employ both types of generators and while we incline to the view that their successful use is dependent more on the operator's familiarity with the apparatus than on the physical principles involved, there are essential differences in the currents. The steady, undamped oscillations of the vacuum tube generator provide an ideal current for cutting purposes, so far as current penetration and cleanliness of the incision are concerned. However, it is highly advantageous to have insignificant primary bleeding, especially when operating on large obstructions, and this is best accomplished, we find, by means of the spark gap machine. This advantage depends on deeper current penetration, and while we have had no complications in our own work attributable to deep electrocoagulation, there are the potential dangers of sloughing and stricture formation, both of which complications have been experienced by others. We have under our care at the present time a case of extensive stricturing of the prostatic urethra which followed resection performed by an expert some fourteen months ago.

In our series there have been instances of secondary hemorrhage, one of which occurred sixteen days after resection, the others within twenty-four hours. Reapplication of electrocoagulation was necessary in one case the bleeding in the others being controlled by irrigations. A sudden inexplicable rise in systolic blood pressure to 235 explained the bleeding in one case.

At the outset of operations for large tumors, it is essential to work rapidly with a minimum of bleeding; this is best accomplished with the spark gap generator. It is often desirable, especially when nearing the completion of an operation, to work slowly, accurately and with a minimum of current penetration, which is best accomplished with the vacuum tube machine.

CURATIVE RESECTOSCOPY

Resectoscopy is spoken of as curative when applied with apparent success in cases of the type hitherto subjected to prostatectomy. The term is thus employed with the reservation that the permanence of the mechanical restoration is conjectural.

Since Dec 1, 1931, 140 patients with urinary obstruction due to benign hyperplasia of the prostate gland have been operated on in our clinic, and of these 80 (57 per cent) have had resections. As our experience grows, the proportion of cases subjected to resectoscopy increases, at the present time the method is employed in approximately 65 per cent of our cases. This is attributable largely to greater mechanical aptitude, but better judgment in the selection and preparation of cases likewise plays a part.

In discussing the selection of material, it is essential to consider not only the type of obstruction and the relative skill of the operator but also that which is of equal importance, namely, the classification of cases on the basis of local and general complications, which influence, often profoundly, the outcome of whatever operation is employed. The clinical data given in table 1 show that, while the largest tumors were excluded,

TABLE 1—Clinical Data

Age Incidence		Residual Urine	
Under 40	7	None	3
40 to 49	9	Acute retention	17
50 to 59	20	300 to 500 cc	11
60 to 69	28	500 to 1 500 cc	7
70 to 79	14	Average	220 cc
80 to 89	2		
Predominant Symptom		Size of Prostate on Rectal Examination	
Acute retention	17	Normal	3
Frequency and urgency	9	Grade 1	35
Difficulty	40	Grade 2	27
Hematuria	7	Grade 3	15
Pain	2		
Average Duration of Symptoms		Cystoscopic Classification	
39 5 months		Commissure and lateral lobes	35
		Commissure chiefly	30
		Middle and lateral lobes	7
		Large middle lobe	4
		Lateral lobes	1
Preoperative Complications			
Local		General	
Hematuria		Psychasthenia	2
Epididymitis		Insanity	1
Urinary infection		Arthritis	4
Acute pyelitis		Severe cardiovascular lesions	16
Prostatic abscess		Diabetes	3
Calculus (vesical)		Cataract	1
Calculus (ureteral)		Horseshoe kidney	1
Hydrocele		Uremia	2
Neoplasm		Hemiplegia	1
		Alcoholism	3
		Syphilis	1
		Tuberculosis and other pulmonary lesions	1
		Perniciou anemia	1

advanced prostatism and serious complications were not uncommon.

Considering first the mechanical problems dependent on the size, shape and location of the obstructive mass, we find that the difficulties and, to a lesser degree, the dangers of resection increase in almost direct ratio with the vertical diameter of the tumor. In more than 40 per cent of cases this is approximately that of the distance traversed by a full excursion of the electrode. These are ideal from the mechanical standpoint for resection, the difficulties of which are usually encountered when multiple cuts in the same horizontal plane are necessary. The degree of prostatism bears no fixed relationship of course to the size of the obstructive mass, but the majority of cases presenting the ideal physical conditions for resection are relatively early in prostatism and not often seriously complicated. Thus in thirty-two of forty-two noncomplicated cases in this series no preoperative treatment was thought necessary and with few exceptions recovery was rapid and

uncomplicated. With this group there has been little or no operative difficulty. In one instance, extraperitoneal extravasation of urine occurred two weeks after operation and after one week of normal voiding. We have ascribed the complication to operative injury, although rough catheterization is an equally rational explanation. This patient recovered after a prolonged convalescence.

It is our belief that, in the treatment of uncomplicated reasonably early prostatism dependent on small and moderate sized obstructions, resectoscopy should, and doubtless will, replace prostatectomy.

Again considering the problem of resection in the case of large tumors from the technical standpoint, we admit the mechanical possibility in the great majority of cases. In uncomplicated cases of this type, resection can be done by the skilful operator with mechanical success and possibly no greater primary mortality than follows prostatectomy in similar cases. To suppose that the inexperienced resectionist could accomplish the same results is ridiculous, and it is to be regretted that the dangers and difficulties of resectoscopy have been understated, thus leading the credulous to pay the price of an appalling mortality and morbidity.

An important group comprises advanced, complicated cases, and especially those in which the tumors are very large. In approximately 10 per cent we find resection either impossible for mechanical reasons or inapplicable owing to bladder complications demanding open surgery. In an additional 20 per cent, our experience does not justify the adoption of resection, which is attended by poor results attributable in part to mechanical failure but more often to complications, fatal or otherwise, representing largely the price paid for mechanical success.

Special interest attaches to eight cases in the series in which drainage by cystotomy was provided. In the majority of these cases, two-stage prostatectomy was anticipated, but restudy disclosed enough shrinkage of the tumor to justify resection, or the latter was selected as the least traumatic procedure. In a number of cases not included here, carcinoma obscured by edema and congestion became evident after dehydration through drainage, and in two instances study of the excised tissue revealed unsuspected carcinoma.

Restudy should be done as a routine after drainage even in cases which at the outset presented impassable obstructions or in which examination through the open bladder disclosed large intravesical masses. In a surprising number of such cases, resection will prove to be the method of choice.

In considering complicated prostatism from the prognostic standpoint, one cannot divorce the influence of technical difficulties encountered at operation, but the direct consequences of preoperative complications are shown in thirty-three cases, in few of which were the resections difficult or prolonged. The average total hospitalization for this group was 36 days, as contrasted with 11.7 days, of which 5.8 days comprised the average postoperative period for noncomplicated cases. In the majority of complicated cases long hospitalization was due to prolonged preoperative treatment. The possible consequence of complications is illustrated in the three deaths in the series, all of which occurred in serious risks. The obstruction in one of these cases was moderate in size, in the others quite large. The question arises in this connection whether a reasonable choice can be made between enucleation and resectos-

copy on the basis of their relative dangers in super-serious risks. Our personal experience in the matter, while conflicting, leads us nevertheless to the conclusion that generalizations in this regard are valueless. Two of the three deaths occurred in cases in which enucleation was considered desirable but too hazardous. Both of these patients had large tumors with complete retention, both had preliminary suprapubic drainage, one for a period of three months prior to resection. The latter patient died of cerebral hemorrhage ten hours after operation, while the other, who survived delirium tremens following cystolithotomy, developed fatal pneumonia five days after resection. The autopsy in this case disclosed some perivesical hemorrhage which we attributed to excessive cutting in the region of the anterior commissure.

We cannot escape in retrospect the thought that one or possibly both of these patients might have survived enucleation which is less traumatic in cases of this type than necessarily prolonged resection.

Conflicting evidence is found in the results obtained in other cases of a somewhat dissimilar type so far as the type of obstruction is concerned. An illustrative case is that of a Negro admitted to the wards with a comparatively small but impassable obstruction and uremia. The blood creatinine content was 12.5 mg. This patient not only survived cystotomy but had a successful resection and remains mechanically well eight months after operation. Incidentally, the minimum creatinine has been 4.5 mg.

The third death, which occurred on the sixteenth postoperative day after easy resection of a moderate-sized obstruction, was due to rekindling of a joint infection and empyema of the gallbladder.

TABLE 2—Operative Data

Preoperative Treatment			
None	32	Bladder lavage	4
Catheter drainage	17	Internal medication	15
Cystotomy	6	Vasectomy	2
Cystolithotomy	2	Epididymectomy	2
Average duration of catheter drainage 11 days			
Average duration of suprapubic drainage 35.5 days			
Anesthesia			
With few exceptions (sacral or lozen) spinal anesthesia used (procaine hydrochloride 50-150 mg.)			
Average time of operation 33.5 minutes			
Difficulties Encountered			
None	73	Difficult to control bleeding	2
Profuse traumatic bleeding	1	Difficult instrumentation	2
Difficult to distend bladder	2		
Local Postoperative Treatment			
Drainage		Duration of Drainage	
None	2	0 to 2 days	20
By catheter	72	3 days	24
By suprapubic tube	6	4 days	10
		5 to 10 days	11
		10 days or more	6
Reasons for Prolonged Drainage			
Acute pyelonephritis	3	Rupture of bladder	1
Postoperative hemorrhage	1	To promote healing of sinus	2
Difficult voiding	1		

Experiences like the foregoing preclude generalizations regarding the relative dangers of resection and prostatectomy in super-serious risks, but it is our opinion that there is nothing to be gained by resection in the case of the individual with a large easily enucleable tumor who has survived cystotomy.

It is of interest that most of the postoperative complications and practically all of the serious ones occurred in patients who presented preoperative complications and that these rather than mechanical problems have given the greatest concern.

TABLE 3—Postoperative Data

Primary Mortality			
3.7 per cent (three deaths described in text)			
Average Total Hospitalization			
42 nonecomplicated cases 117 days			
Average Postoperative Hospitalization			
42 nonecomplicated cases 58 days			
Average Total Hospitalization			
23 complicated cases 263 days			
Complications (Postoperative)			
	Local	General	
Rupture of bladder	1	Retention	3
Cystitis (acute)	2	Repeated operation	3
Pyelitis	5	Hemorrhage	3
Indolent sinus	2		
Pyelonephritis	3	Pneumonia	1
Prostatitis	1	Temperature rise	3
Impaction of gallbladder	1	Chills and fever	1
Angina pectoris	1	Herpes zoster	1
Delirium tremens	1	Carbuncle	1
Cardiac disease	2	Active pulmonary tuberculosis	1
Uremia	2		
Readmissions (6)			
1 Volvulus 1 month after resection died after operation autopsy disclosed large (cylindrical) lined tunnel through prostate			
2 Reoperation for complete retention 35 pieces of tissue removed perfect recovery after second revision			
3 Reoperation for frequency urgency and 200 cc retention 7 pieces of tissue removed complete recovery			
4 Hemorrhage 16 days after revision controlled by catheter			
5 Hemorrhage from trigon biopsy specimen inflammatory ulcer			
6 Terrible anuria and hemiplegia 8 months after operation died			
Final Results in 75 Patients Living			
Mechanical	Symptomatic		
All good or perfect	Burning on urination	1	
	Frequency marked	0	
Average Duration of Urethral Convalescence (6 weeks)			
Note—In cases complicated by chronic prostatitis prolonged postoperative treatment is necessary			

The final results in the series have been satisfactory. All of the seventy-five living patients are mechanically well. From the symptomatic standpoint, there are sixteen who are not entirely well, thirteen of these complain of some burning on urination and three of frequency, the latter in two instances being attributable to polyuria incident to nephritis. The average duration of the urethral convalescence has been about eight weeks. There have been six readmissions for reasons given in table 3.

PALLIATIVE RESECTOSCOPY

Palliative resectoscopy implies, in the case of benign prostatic hyperplasia, an attempt to overcome urinary obstruction partially in cases in which the completed operation seems inapplicable. This presupposes hazardous conditions necessitating a minimum of trauma. Under such circumstances, palliative resectoscopy may be performed, perhaps in multiple stages, small amounts of tissue being removed at each sitting and a total amount sufficient to restore reasonably satisfactory voiding. The applicability of this depends largely on the successful use of local anesthesia, with which extensive resections are possible, as illustrated in the case

of an individual with a systolic blood pressure of 250 from whom we removed thirty large segments of tissue painlessly after infiltration of the area with procaine hydrochloride solution (2 per cent) colored with indigo carmine

Preliminary dehydration of the obstructive mass by diathermy is a phase of the problem that has future possibilities in the treatment by partial resection of large obstructions in serious risks

Palliative resectoscopy has proved the first completely satisfactory method of overcoming prostatism due to carcinoma. If dedicated to this alone, the procedure would be a monumental contribution to urologic surgery. There is no evidence to indicate that the operation hastens local growth of the neoplasm or promotes its dissemination. Restudy of the excised tissue revealed carcinoma in one instance, thus explaining a malignant condition of the spine, which appeared ten months after operation. The complete absence of local evidence of the disease in this case seems remarkable.

Resectoscopy followed by high voltage roentgen therapy is the most satisfactory means of promoting the comfort if not prolonging the life of the individual with an inoperable, obstructive carcinoma of the prostate gland.

We have resected neoplasms of the deep urethra together with obstructive prostatic tissue in three cases: two papillary carcinomas, the other a squamous cell tumor. The ease and completeness of the procedure contrasts strongly with the unsatisfactory methods hitherto available.

Mention may be made of the applicability in the palliative sense of resectoscopy in chronic prostatitis associated with and possibly maintained by minor obstructions at the bladder outlet. Removal of the obstruction, whether fibrous or glandular, does not cure the prostatitis but frequently makes theretofore incurable infections curable by ordinary measures.

PROPHYLACTIC RESECTOSCOPY

Prophylactic resectoscopy refers to the excision of incipient prostatic obstructions with the hope of arresting the hyperplastic tendencies in the remaining tissue, thereby removing the future possibility of advancing prostatism. It implies, too, in the event of failure to accomplish this, the arrest, at least for a time, of the clinical and anatomicophysiological manifestations of prostatism. The progress of the latter can be arrested for an indefinite period by the early restoration of urinary freedom but the duration of the mechanical correction remains to be determined. As radical prostatectomists we have been accustomed to deal for the most part with the end results of a morbid process the stimulus to which has largely if not completely expended itself. We now propose through partial resection to arrest a tendency which is widespread in the prostatic tissues of certain individuals and at a time when the power of growth is at its maximum. Our series contains three instances of recurrent obstruction, two of which followed electrosurgical excision (Collings method), the other, excision by the Caulk method of glandular bars. On the whole however our experience is well as that of others with former methods used in the treatment of glandular bar prostatism indicates surprisingly little tendency to early recurrence and the same will prove true in all probability of resectoscopy in similar cases. Nevertheless while we are fully justified in advising early resection, the circumstances obligate us to a conservative attitude.

1601 Walnut Street

INDIVIDUALIZING THE PROSTATIC PATIENT IN SELECTION OF TREATMENT

WILLIAM J ENGEL, MD

AND

WILLIAM E LOWER, MD

CLEVELAND

There is probably no one who will disagree that the development and perfection of transurethral resection of the prostate have made available a valuable method for the treatment of prostatic obstruction. The value of prostatectomy has long been recognized, so long in fact that some have forgotten that it too has its shortcomings. However, prostatectomy has already been through the mill of controversy that resection is now passing through and our experience convinces us that both will survive. Thus there now are two successful methods of handling the prostatic patient so that each case must be carefully studied and individualized and the treatment selected that assures the patient relief in the simplest, safest way. We decry the popular belief that resection is the simplest in all cases but our experience justifies the statement that it is a more conservative operation and has a larger factor of safety than prostatectomy. With these considerations in mind, how shall one approach the prostatic patient?

Our conclusions as to the value of transurethral resection are based on a series of 198 operations on 194 patients. All types of prostatic enlargement have been included during the course of our experience with the method and all cases have been carefully followed. By personal visit or correspondence we know the present status of all but fourteen of the cases in this group and have kept a check on the subjective state, the amount of residual urine, and the general condition of the patient. We feel very strongly that the immediate postoperative result is only one item in evaluation of the procedure, for continued observation of a patient may alter one's conclusions, favorably or unfavorably but in either event one should by all means know the story subsequent to operation.

It is almost literally true that no two cases of prostatic obstruction are alike. There is wide variation in the age and general condition of the patient which classifies him as a good or a bad surgical risk, the history and duration of symptoms differ, the presence of associated conditions in the urinary tract such as infection, stone and atonic bladder must be considered, and the type of gland is one of the most important considerations. When one considers all these factors it immediately becomes apparent that each case is an individual problem and that treatment must be selected accordingly. They may, however, be divided into certain groups.

All cases of prostatic obstruction may first be divided into two classes, according to whether the lesion is malignant or benign. Every patient with a malignant condition of the prostate consulted us because of obstructive symptoms and in all cases diagnosed clinically as carcinoma of the prostate we recommended transurethral resection followed by implantation of radium or high voltage roentgen therapy or both. There have been thirty-four cases of this type in this series with but one death from operation. All the

From the Cleveland Clinic
Read before the Section on Urology at the Eighty-Fourth Annual Session of the American Medical Association, Milwaukee, June 15, 1933.

patients have been relieved of their distressing urinary symptoms and are entirely comfortable, except one with marked local reaction from radium implantation which cannot properly be attributed to the resection. In view of the fact that we have been doing transurethral resections extensively for only about three years, we cannot yet quote significant statistics as to length of life except to say that twenty-one patients are known to be living and comfortable at this time. In one case we have had to do a second resection for recurrent growth causing obstruction. This patient is still alive and in good condition one and a half years after his original operation. The data for this group are presented in table 1.

The cases of benign hypertrophy must be further subdivided and may be placed first into two large groups: (1) the bad risk patients and (2) the good risks. The first group includes the patients tottering with senility, those having severe myocardial damage or angina pectoris, those with severe diabetes, those

with kidney damage that does not improve on pre-operative drainage, and a few patients whose charts show nothing of significance but who, after careful inspection and experience, are considered poor surgical risks. The very obese patient often falls into this category. Regardless of all other factors, we have chosen to handle these by transurethral resection. In this series there have been twenty-eight cases so classified (table 2). Two operative deaths have occurred in this group, one from a fatal attack of angina on the seventh postoperative day and the other in a patient aged 79, with severe kidney damage who developed an oliguria, could not stand the shock of a moderate postoperative hemorrhage, and died in uremia on the second postoperative day.

Operative deaths	2
Complete relief	12
Partial relief	10
No relief	4

Of the remaining patients, twenty-two were restored to urinary comfort and although in several instances they continue to carry some residual urine, this does not give rise to trouble, and the patients consider themselves well. When it is recalled that in all these cases there had been complete retention of urine, we are content to have made a bad situation better and to have a living patient.

Each of the four patients who did not receive relief from the resection had large extravascular lateral lobes, a type that we include now among those cases unsuitable for resection.

We classify the patient as a good surgical risk when we are able to select treatment unhampered by any consideration except the permanent and complete relief of his urinary obstruction. In this group of cases the chief variable is the type of gland and so we may quite properly concern ourselves with which types are suited

for transurethral resection and which for prostatectomy. A summary of the results in 132 cases of this type is shown in table 3.

Careful routine cystoscopy with the cystourethroscope is essential in the selection of cases. This should include careful inspection of the bladder and trigon, the bladder neck and the posterior urethra. The position and depth of the clefts in the bladder neck are important considerations, the degree to which the trigon

1	Simple bilateral lobe hypertrophy
2	Solitary posterior commissural hypertrophy
3	Solitary subcervical lobe hypertrophy
4	Combined postcommissural and bilateral lobe hypertrophy. Here from the point of view of suitability for transurethral resection we have subdivided this group into:
	(a) Predominantly postcommissural
	(b) Predominantly bilateral lobes
	(c) No striking difference
5	Combined subcervical and bilateral lobe
	(a) Predominantly subcervical
	(b) Predominantly bilateral lobe
6	Bilateral subcervical and commissural hypertrophy
7	Anterior lobe hypertrophy
8	Sclerotic median bar
9	Carcinoma

is obscured is another, and the third and possibly the most important is an estimation of the length of the prostatic urethra, which gives an index as to the size of the lateral lobes. It is, of course, understood that digital examination of the prostate through the rectum with and without the cystoscope in the urethra is indicated in all cases.

We have chosen to group our cases according to Randall's classification, which includes the types given in table 4.

With all these facts in mind, one may consider the cases in the following categories:

1 Those ideally suited for transurethral resection with an assured successful outcome.

2 Those not suited for resection in which prostatectomy should be advised

3 A small group of borderline cases in which resection may first be done and, if unsuccessful, may be followed by prostatectomy. In this type of case we have found no resultant ill effects from doing the resection and the prostatectomy at the same hospital admission.

In classifying cases according to suitability for transurethral resection, the criteria given in table 5 are considered. These criteria result in the classification of types suitable and unsuitable for the operation shown in table 6.

The third group in which transurethral resection is tried before resorting to prostatectomy is less well defined, though it is apparent that it falls between the

TABLE 5—Criteria for Transurethral Prostatic Resection

Suitable	Unsuitable
1 Moderate enlargement by rectum	1 Pronounced enlargement (not necessarily unsuitable)
2 Cystoscopically	2 Cystoscopically
(a) Middle lobe small to moderate size	(a) Middle lobe very large
(b) Absence of pronounced intravesical extension of lateral lobes	(b) Marked intravesical lateral lobes
(c) Absence of inverted V shaped cleft at 12 o'clock position	(c) Deep inverted V shaped cleft at 12 o'clock position
(d) Moderate to slight intraurethral lateral lobe encroachment	(d) Marked intraurethral lateral lobes
(e) Absence of lengthened prostatic urethra	(e) Decidedly lengthened prostatic urethra

two extremes represented by the other two groups. This group is extant only because of the variability in size of the glands, especially the lateral lobes, and includes the cases in which the indications and criteria are less well defined. We are inclined in all such cases to do transurethral resection first and, if the result is not satisfactory, to follow with prostatectomy. In fairness it should be stated that many of our best

TABLE 6—Types for Transurethral Prostatic Resection

Suitable	Unsuitable
1 Solitary commissural hypertrophy	1 Simple bilateral lobe hypertrophy
2 Solitary subcervical hypertrophy (excepting those rare ones which attain immense size)	2 The ponderous subcervical lobe or postcommissural hypertrophies
3 Posterior commissural and bilateral lobe hypertrophy with predominance of former that is without marked intraurethral encroachment of the lateral lobes and marked lengthening of the prostatic urethra	3 Any case precluding marked extravesical lateral lobe enlargement; this includes the combined types in which the lateral lobe hypertrophy predominates
4 Subcervical and bilateral lobe hypertrophy in which the same holds true	
5 Anterior lobe hypertrophy	
6 Sclerotic median lobe	
7 Patients having had previous prostatectomy	

results from resection have been in this type of case. There have been twenty cases in this group, with nineteen completely or partially satisfactory results. The single case with no relief occurred very early in our experience and subsequent cystoscopy shows that insufficient tissue had been removed. A second resection has been recommended in this case.

There is another group we should like to mention but for which unfortunately there are no numerical statistics. We refer to those who might be called the neglected prostatic patients. This group includes those

patients who are having definite obstructive symptoms and facing ultimate trouble but have the unfortunate belief that this is just one of the necessary accompaniments of advancing years. When prostatectomy was the only method of relief, the personal physician and even the urologist postponed operation in these cases until relief became imperative. Now armed with a distinctly less formidable and more conservative procedure, these patients should all have early treatment, as it is probably safe to say that they would all be suitable

TABLE 7—Summary of Results in Transurethral Prostatic Resection

for resection. Convinced as we are of the efficacy of transurethral resection, a campaign of this sort would still further reduce the number of patients who at the present time require prostatectomy for relief.

A summary of the immediate mortality in 194 cases of transurethral prostatic resection is shown in table 7.

ABSTRACT OF DISCUSSION

ON PAPERS OF DR. ALCOCK, DR. HERMAN AND GREENE, AND DR. ENGEL AND LOWER

DR. HERMON C. BUMPUS, Rochester, Minn. These three papers adequately emphasize the salient features of transurethral resection of the prostate gland, one of which, referred to by Dr. Alcock, I wish to enlarge on, namely, the control of infection both before and after operation. Because patients with highly infected urine and impaired renal function usually improve under preliminary drainage by either urethral catheter or suprapubic cystostomy, the idea has been general that such preliminary drainage is imperative prior to any operation on the prostate gland. So firmly has this dictum become established that many surgeons refuse to operate unless preliminary treatment in the form of urinary drainage has been carried out for an arbitrary period ten days often being considered the minimum. In the absence of urinary or prostatic infection, such a period of drainage carried out by means of an indwelling catheter is bound to result in infection and what before was a mild inflammation of the prostate gland causing no reaction is activated to virulence often alarming, and the patient becomes a poorer instead of an improved surgical risk. For this reason, during 1932, my associates and I performed transurethral resection on 45 per cent of the 276 patients operated on without any preliminary preparation and could not detect that their postoperative course was essentially different from that of the patients who had previously had the most painstaking preoperative preparation. Of the remaining patients, 19 per cent were prepared by suprapubic drainage and the others by urethral catheter either indwelling or intermittent. There were no deaths in the series. The low mortality rate can be attributed largely to our extreme care relative to sepsis. The operation is carried out with a knife punch so that coagulation is used only for the control of bleeding and hence is reduced to a minimum and thus a potent source for secondary infection in coagulated and necrotic tissue is largely eliminated. After the operation the indwelling catheter which is kept in place usually not longer than forty-eight hours is connected to a sterile tube running into a sterile bottle. This bottle is not taken to the lavatory and emptied with the inevitable tendency for the distal end of the tube to fall to the floor or be tucked under the mattress or lie on the soiled bedding. Instead the nurse replaces the filled bottle with a sterile one. Disconnection is not permitted from this bottle and the system is kept closed except

when opened for duly lavage of the bladder, which is conducted under the most rigid aseptic conditions

DR A. I. FOLSOM, Dallas, Texas. My experience has been most satisfactory and I am delighted with the results of this procedure. I have operated on 205 patients by the resection method and only three patients by prostatectomy in the past year. One of these was a case in which I made a mistake in diagnosis and went in for carcinoma, intending to put in radium needles, but found an adenoma instead. I do not agree with Drs. Alcock, Engel and Lower that urethral bulgings are not amenable to this type of operation. They are perfectly amenable to it. I have resected 17 Gm of lateral lobe when I had only a small commissure in the middle. I took the tube out on the fourth day and the patient could not urinate at all although he could a little before the operation. I went in the second time and saw two larger lateral lobes than I had the first time. I could explain this by the fact that in the original operation I removed a portion of the capsule and in doing that removed the retaining wall, which allowed more prostatic tissue to be squeezed out into the cavity. As to infection in the analysis of 177 cases the temperature was normal in 46 per cent on the operative day and remained normal throughout that day, it became normal in 29 per cent on the first day, in 50 per cent on the second day and in 83 per cent on the fifth day. 29 per cent of the patients had a temperature of 100 F on the operative day, and only 0.9 per cent had over 100 F on the operative day. In my experience this has been one of the most startling things about the operation. One should have chills and fever after a rather radical transurethral manipulation, yet it has been surprising how few reactions there were. Postoperative hemorrhage has been offered as one reason why this procedure should not be used. One does have hemorrhage in prostatectomies, but in this procedure one has one of the most delightful ways of controlling it that I know of. As Dr. Bumpus said, evacuation of the clots controls the hemorrhages in most instances. If necessary one can open, find the bleeding point, and control it in that way.

DR IRVIN S. KOLL, Chicago. I wish to know the average number of days spontaneous urination occurred following removal of the catheter in Dr. Alcock's cases.

DR HERMAN L. KRETSCHEMER, Chicago. Transurethral resection has supplied a new point of view in the treatment of the patient with prostatic obstruction. The subject at this time is in a state of flux and naturally, there are individual differences of opinion regarding the cases suitable for this form of treatment. There are some who use transurethral resection for all cases, while others use it only in selected cases. Since March, 1932, I have not performed a surgical prostatectomy but have treated all cases of prostatic obstruction with the resectoscope. My experience is based on a series of 250 resections performed on 207 patients. The difference in the number of operations and patients is due to the fact that in 10 per cent it was necessary to do a second resection and most of these were among the early cases. In this series the mortality was 3.9 per cent. I agree with Dr. Alcock that it is not the bleeding that kills the patients but infection. I believe that as time goes on the mortality rate will be reduced because the patients will come in earlier. Part of the relatively high mortality is due to the fact that a certain number of patients are very poor risks—that they are sent in for resection because they cannot possibly stand a surgical operation. As has been brought out in these papers, many of the patients have other serious organic lesions. Thus in my series there were ninety patients who had serious organic disease of the heart. My experience is in accord with that of the men who spoke of the fact that the stay in the hospital is shorter than with prostatectomy. In one group the average postoperative stay in the hospital was 6.7 days. In cases prepared by suprapubic cystostomy the average postoperative stay was fifteen days. Regarding some of the complications. Since doing routine vasectomies I have had no cases of epididymitis. Prior to this I had about 15 per cent. There was only one case of severe primary hemorrhage that demanded a suprapubic cystostomy. There were nine cases of secondary hemorrhage. In seven of them it was only necessary to evacuate the clots and to irrigate with a hot solution of potassium permanganate. In two cases

it was necessary to insert the resectoscope and excise the bleeding point. The postoperative temperature in this series was in agreement with the statements made here.

DR H. W. E. WALTHAM, New Orleans. I want to stress four factors in transurethral prostatic resection to which I have devoted much attention: (1) the minimizing of fever, (2) the prevention of epididymitis, (3) the anticipation of surgical shock and (4) the selection of the anesthetic. For four or five days prior to the resection I give two 0.1 Gm tablets of pyridium by mouth thrice daily and I know that by using this dye I have had less febrile reaction. I cannot understand the tardiness with which many urologists have adopted bilateral vasosection in the preparatory scheme. I have never had epididymitis complicating resections because I have always done preliminary vasosection. Surgical shock must be anticipated even though less of it occurs with resection than with prostatectomy. In men over 65 years of age surgical shock is ever a factor to reckon with. To preclude this possibility I always match and type bloods the morning of resection, and immediately following operation the patient is given 250 cc of whole blood by the direct method. This plan has been followed in all my resections and I have not observed a case of surgical shock since adopting it. I find that spinal, sacral or local anesthesia either relieves the sphincter too much or distorts the working field to such a degree as to impede good work. Therefore nitrous oxide and oxygen inhalation anesthesia is used in the clinic in which I work and I believe it superior to other methods for transurethral prostatic resection.

DR W. J. ENCLER, Cleveland. I suppose there will never be a unanimous opinion as to the applicability of transurethral resection but each urologist will have to work this out in the light of his own experience. Our experience agrees with that of Dr. Bumpus in the matter of the shortened preoperative preparation. Of our cases 38 per cent had only one day of preoperative preparation and 70 per cent had three days or less. In those cases which require suprapubic drainage we often resort to suprapubic puncture instead of doing a cystostomy. We use a trocar with a sharp point which is plunged into the bladder. Then if we wish a No. 18 cysto-urethroscope can be introduced through the sheath and the bladder neck viewed from above. A No. 18 soft rubber catheter is then threaded through the sheath, which is then removed leaving the catheter for drainage. We have not seen any leakage or other complications from handling cases in this manner. Regarding the large bilateral lobe cases which Dr. Folsom considers suitable we feel that prostatectomy is to be preferred to multiple or prolonged resections in the good risk patient. In only three cases have we done more than one resection. In view of the hospital stay, one does not reduce it much in doing multiple resections. Estimated on the basis of resections and prostatectomies done in the past year and a half we believe that about 75 to 80 per cent of cases will be found suitable for resection. Dr. Kretschmer's analysis of complications corresponds rather closely to our own.

DR N. G. ALCOCK, Iowa City. As to the average number of days before spontaneous urination, I may state that I take the catheter out as a routine on the second day. As a rule that is when the patients begin to urinate. If there is any indication for leaving it in longer I replace it. The most striking change that has taken place regarding transurethral resections is the fact that the men who were either radically opposed to it or very doubtful about this procedure a year ago are now doing it.

Localization Theory Must Be Changed—The classic localization theory with its assumption of a sharp, point to point geometric projection of the body on the cortex with its centers for separate psychic functions must be changed. It was born prematurely. The workers in the years immediately following the discoveries of Hitzig and Fritsch were carried away by enthusiasm. This is the almost inevitable fate of all who share with the privileges the dangers of working in a period of great momentum and as such one certainly can consider the years immediately after 1870 in the field of neurophysiology and neurology.—De Barenne, J. G. *Dusser Arch. Neurol. & Psychiat.* 30:884 (Oct.) 1933

CHRONIC BILIARY STASIS

TREATMENT BY CHOLEDOCHODUODENOSTOMY AND
GASTRO-ENTEROSTOMYALFRED A. STRAUSS, MD
SIEGFRIED F. STRAUSS, MD
ROBERT A. CRAWFORD, MD
AND
HERMAN A. STRAUSS, MD
CHICAGO

The internist confronted with chronic jaundice in a young patient usually diagnoses it as catarrhal jaundice. If he encounters it in an older patient, he is likely to consider it as due to carcinoma of the head of the pancreas. The surgeon, on exploring, may find no carcinoma at the head of the pancreas and no stones in the common duct. He then usually performs a cholecystectomy, or a cholecystectomy and drainage of the common duct, or he decides that he is dealing with intrahepatic cirrhosis with jaundice and closes the abdomen without further intervention. We believe that in such cases the condition is due to an infection which begins as duodenitis and ascends the pancreatic and common ducts. This triangular infection produces inflammation and hypertrophy of the ampulla of Vater, which in turn give rise to spasm and obstruction of the common duct, biliary stasis and ultimately a breaking down of the liver cells and cirrhosis.

As proof that our contention is correct we present twenty-two cases in all but two of which cures followed when we did away with the obstruction in the common duct and side-tracked the infection by cholechochoduodenostomy and gastro-enterostomy. In seven other cases we obtained cures by the following surgical procedures: in four by drainage of the common duct alone, in one by gastric resection and cholecystoduodenostomy, and in two by cholechochoduodenostomy alone. In these twenty-nine cases the destruction in the liver had not proceeded so far that regeneration could not take place when the obstruction in the common duct was relieved. The remaining ten cases were found in patients so critically ill that only drainage of the common duct could be attempted. These ten patients died of the disease within two years. It is clear therefore, that as regards surgical intervention the element of time is of great importance.

We arrived at our analysis of the condition and at the method of treating it somewhat fortuitously.

In 1918 we operated on a man, aged 38 who had been deeply jaundiced for two months and who had had mild attacks of pain in the region of the liver. He was emaciated and had the appearance of one suffering from a carcinoma of the head of the pancreas. At operation we found a mass at the head of the pancreas having the appearance of a small carcinoma. The gallbladder was markedly inflamed and distended which threw some doubt on the diagnosis of carcinoma. The

common duct was likewise markedly distended. In preference to anastomosing the thickened and inflamed gallbladder to the stomach, the gallbladder was removed and a cholechochoduodenostomy was performed. When the common duct was opened, we found definite thickening and narrowing (edema and infiltration) at the ampulla, and when the duodenum was opened for the purpose of the anastomosis, we saw a large, swollen, reddish, nipple-like projection where the papilla of Vater empties into the duodenum. The anastomosis was of the side-to-side type by a technic similar to the one which will be described later. The patient's jaundice disappeared in three weeks and much to our surprise he gained 30 pounds (13.6 Kg). The conclusion reached was that he had had obstructive inflammatory hypertrophy of the ampulla of Vater and resulting obstructive inflammatory pancreatitis, and that when this process was side-tracked and the intraductal pres-

Fig. 1—Roentgenogram showing a barium sulphate meal that has passed through an anastomosis of the common duct and duodenum into the hepatic bile ducts.

sure was relieved by the lateral cholechochoduodenostomy, he made a complete recovery. At the time of writing fourteen years after the operation, he is in perfect health.

In a third case of like nature, five weeks after operation the patient was seized with colicky pains, fever and chills and showed mild intermittent jaundice. On fluoroscopy with a barium sulphate meal we noted that the barium sulphate passed through the anastomosis of the common duct and duodenum into the hepatic ducts and filled many of the small ones (fig. 1). Some of the barium sulphate remained in the hepatic ducts for from twenty-four to fifty-six hours. The conclusion reached was that the regurgitation of food into these ducts gave rise to cholangitis and hepatitis. We believed that the regurgitation of the barium sulphate into the liver was due to increased intraduodenal pres-

Because of lack of space the article is abbreviated in THIS JOURNAL by the omission of some of the illustrations. The complete article appears in the author's reprints.

Read before the Section on Surgery, General and Abdominal, at the Eighty-fourth Annual Session of the American Medical Association, Milwaukee, June 14, 1933.

The author was carried on by the aid of a grant from the Louis I. Kahn and Koppelman Fund to the Research Group of the Michael Reese Hospital. The organization of the research group is as follows: Alfred A. Strauss, M.D., Siegfried F. Strauss, M.D., James Patey, M.D., George J. Meyer, M.D., Herbert Burwanger, M.D., Medical Director, William Thibodeau, M.D., O. S. Burdette, M.D., Heinrich Neuberger, M.D., Physicist, Robert A. Allen, M.D., Technologist.

sure from the peristaltic contractions which could be relieved by performing a gastro-enterostomy well over on the left side of the stomach. We performed this operation, and the patient's symptoms disappeared. On fluoroscopy we could not force any barium sulphate through the anastomosis of the common duct and duodenum into the hepatic ducts (fig 2)

Fig 3—Section of the liver of a new born baby who had a complete atresia of the common duct up to the hilus of the liver. The section shows a breaking down of liver cells and an interlobular cirrhosis due to the irritation caused by mechanical retention of bile

On the basis of the observations in the two cases just cited, we subsequently performed choledochoduodenostomy and gastro-enterostomy on twenty other patients with chronic biliary stasis. We have also performed these operations on five patients with multiple recurrent stones in the common duct.

Patients with chronic biliary stasis can be divided into three groups symptomatically: first, those who have severe colicky attacks simulating gallstone attacks, without jaundice; second, those who have mild, continuous jaundice without acute attacks, in some of these, the jaundice is so mild that it may be overlooked; third, those who have deep silent jaundice. They all have, as the pathologic basis of their symptoms, an infiltrative inflammatory process of the lower portion of the common duct, with thickening and narrowing of the ampulla of Vater. This inflammatory process varies from an extremely mild one to one of the most severe intensity.

We had eight patients of the first type. They had typical colicky attacks simulating gallstone attacks, without jaundice. At operation, there was found a questionable mildly inflamed gallbladder without stones, but with some pericholecystic adhesions and a fairly large common duct. In four of the cases, mild pancreatitis was noted. Cholecystectomy was performed. A few weeks later these patients were again having attacks. Drainage of the common duct was performed, the drainage being maintained for from four to six weeks. At this operation it was noted that only a fine probe could be passed through the papilla. On palpating along the probe, one could ascertain marked thickening and infiltration at the ampulla. The duct was dilated with graduated sounds and a specially constructed dilating instrument so as to stretch and paralyze the sphincter. After this procedure, four of the patients remained well. Their cases were probably of

the type that Judd and Walters of the Mayo Clinic described. The remaining four patients had more severe attacks than ever, beginning within a few months after the second operation. These attacks were numerous and so severe that the patients insisted that something be done for their relief. Choledochoduodenostomy and gastro-enterostomy were performed. All were relieved of their attacks and have remained well. In these cases we were dealing with inflammation and hypertrophy of the papilla of Vater, which produced spasms of the common duct and colicky attacks and which was relieved by choledochoduodenostomy and gastro-enterostomy.

If one considers the sphincteric control of the papilla of Vater in the same light as the sphincteric control of the pylorus of the stomach, one can readily see the similarity here to the pylorospasm, edema and infiltration of the pylorus due to a reflex condition or to an ulcer in the midsection or lower portion of the lesser curvature of the stomach.

We had eleven patients of the second type. These patients had mild jaundice with mild pain in the upper part of the abdomen. They had a peculiar pale "live like" appearance, with marked lassitude and weakness and mild symptoms referable to the upper part of the abdomen with some tenderness over the liver. Two of these patients had been treated for several months by skin specialists for severe itching with no jaundice that could be discerned by the naked eye, while nine of them had mild jaundice which had lasted for from six weeks to six months. The two who had itching of the skin were discovered to have mild jaundice only when the icteric index was shown to be 25 and when it was noted on careful examination of the urine that the test for bile was occasionally positive. In all the other cases, bile was found in the urine and in the

Fig 6—Drawing showing the relationships of the subtotal gastrectomy and the anastomosis between the gallbladder and the cut end of the duodenum

stools at all times. At operation these patients showed a mildly inflamed gallbladder—in four cases, with pericholecystitis. The liver was large and showed marked cirrhosis. The common duct was only moderately distended, but in the lower portion it was thickened and inflamed. The periductal areolar tissue was adherent

to the duct and was freed with difficulty and marked bleeding. The pancreas was hard, swollen and lobulated, and in four of the cases the omentum of the lesser curvature of the stomach was tightly adherent to the capsule, which, when loosened, disclosed marked capillary hemorrhagic infiltration of the pancreas. The gallbladder was removed. The common duct was

Fig 9—Striking increase and new formation of connective tissue in the periportal spaces, chronic cholangitis with an extensive infiltration of lymphocytes, marked degeneration of the hepatic cells.

opened. In three cases it contained water-clear bile. The opening into the duodenum was narrow, a fine probe could be passed only with difficulty, with the exception of two cases in which the probe passed easily. In these two cases we noted that there was a marked infiltration of the common duct almost up to the cystic duct, an infiltration which could easily interfere with the peristalsis and the onward movement of the bile and which explained the stasis. At operation in all cases, a section of the liver was taken for histologic examination. Choledochoduodenostomy and gastro-enterostomy were performed on all these patients, and all made uneventful recoveries.

We have operated on ten patients of the third type. They had deep, silent jaundice with mild or no pain, but some tenderness in the upper part of the abdomen and usually a large, swollen liver. Five had had previous attacks. At operation we usually found a large, dilated, inflamed gallbladder, a considerable number of large lymphatic glands along the common duct and a large, swollen greenish-black liver. In one case the liver took up the greater part of the abdomen. The common duct in these cases was markedly distended and in five cases it was almost as large as the duodenum. When the common duct was opened in these five cases a hydrops of water-clear bile was found both in the common duct and in the gallbladder. A fine probe could be passed through the common duct into the duodenum only with difficulty. The pancreas was hard, swollen and lobulated. Choledochoduodenostomy and gastro-enterostomy were performed on all these patients except one on whom no gastro-enterostomy was done. All but two made uneventful recoveries and remained well. One patient aged 58 suffered from hemiplegia on the sixth day and died. Another patient aged 68 died of a postoperative pneumonia.

The water-clear bile in three cases was due to the inflammatory partial obstruction at the outlet of the common duct which produced mild back-pressure and stasis, thereby causing a chemical irritation and breaking down of the liver cells. This prevented the secretion and excretion of the bile and its pigments. The water-clear bile was the product of the epithelium of the hepatic ducts. The vicious circle established between the infection and the chemical irritation from bile stasis produced the interlobular cirrhosis and breaking down of the liver cells to varying degrees. In some cases, this was so extensive as to produce a picture almost identical with that of subacute yellow atrophy.

To illustrate that mechanical retention of the bile within the liver acts as an irritant producing a breakdown of the liver cells and interlobular cirrhosis, we have the sections of a liver (fig 3) in a new-born baby who had complete atresia of the common duct up to the hilus of the liver. We found that the duct within the liver was patent. The duct was drained with a no. 12 catheter. In about six weeks a spontaneous anastomosis occurred between the duodenum and ducts in the hilus of the liver, the catheter acting as a foreign body. The catheter was removed at the end of three months. The jaundice disappeared, and the baby was well at the time of writing. Sections of the liver of this baby taken at the operation show a definite degeneration of the liver cells and an increase in the interlobular connective tissue which, in this new-born baby, was definitely caused by chemical irritation due to the mechanical retention of the bile and not to infection.

Fig 10—A shows interrupted fine waxed silk sutures of the Lembert type attaching the common duct to the duodenum. B, various types of incision used in the common duct.

To illustrate the varying effects of this type of chronic obstruction of the common duct on the liver over a period of years, we shall cite two typical cases.

The first case was that of a man aged 51 who had a history of nine months of jaundice. He had repeated chills and fever with a temperature of 105 F, and was bronzed almost black.

At an emergency operation, we found a tremendous greenish-black liver which filled the greater part of the abdomen. The gallbladder was large and distended. The common duct was almost the size of the duodenum, and there were a number of large glands along the duct. The common duct and the gallbladder contained a clear fluid and flakes of pus. Only the finest probe could be passed through the papilla, and this with difficulty. The pancreas was large, swollen and hard. The duodenum also showed some infiltration and inflammation. The gallbladder was removed, and drainage of the common duct with a no. 14 catheter was established. The tube remained in the common duct four months, after which a biliary fistula was established. It took four months for the jaundice to disappear completely. Eight months after operation the fistulous tract was dissected free. A stricture was found at the point below the fistula of the common duct, and there was a marked obstruction at the papilla. The fistulous tract was anastomosed to the duodenum, but no gastro-

pallor. Three times during this period of twenty-six years she noticed that she was mildly jaundiced. After she had been given several transfusions of blood, we operated. We found a small hob-nailed liver about one fourth of its normal size, a large carbuncle-like ulcer of the duodenum just above the papilla of Vater (fig. 4), a markedly thickened pipe stem infiltration of the common duct, extending almost to the cystic duct, and many large glands along the common duct. The gallbladder was only mildly inflamed. On account of the extensiveness of the ulcer, which formed a mass the size of a small egg and on account of the marked infiltration of the common duct, we decided, in spite of the deep jaundice, to do a subtotal gastrectomy. The ulcer was excised, and the jaundice was relieved by anastomosing the gallbladder with the cut end of the duodenum (figs. 5 and 6). It was impossible to anastomose the inflamed common duct with the duodenum, since the ulcer was at the point where the anastomosis would be made. The patient's jaundice disappeared within six weeks. Five years after operation, she had gained 30 pounds and was in good health in spite of the fact that she had a definitely hob-nailed liver one fourth its normal size.

The hob-nailed liver can be explained on the basis of an infection ascending from the ulcer near the papilla which the recurrent attacks of inflammation and infection produced. This ulcer was known to have existed for twenty-six years. If this cirrhosis and hob-nailed liver were of a constitutional or intrahepatic type and not of the obstructive type the patient would not have recovered and would not be in good health at this time.

In by far the largest number of cases of jaundice associated with stone in the common duct the condition is due to the edema swelling and inflammation of the ampulla rather than to the stones. The stones and debris in the common duct act merely to maintain the inflammatory process. It is only occasionally that a stone is wedged into the papilla to produce actual obstruction. In other words, there is no difference in the pathologic basis between the series that we have just described and the cases associated with stones in the common duct except that in the former cases the jaundice is more chronic and in the latter it is more intermittent.

Five patients with recurrent stones in the common duct, from one of whom the stones had been removed twice previously, were operated on by choledochoduodenostomy and gastro-enterostomy. We felt that the stasis produced in the common duct which probably leads to crystallization of bile and stone formation could be relieved by an anastomosis, doing away with the sphincteric control of the papilla, and that if stones should form, they would easily pass through the anastomosis. All of these patients made uneventful recoveries.

We may speculate as to whether or not patients who have suffered from intermittent subacute pancreatitis of the duct-ascending infectious type, characterized by pain in the upper abdominal region, severe pain in the back, diarrhea and in some instances transient glycosuria would not be better relieved by choledochoduodenostomy and gastro-enterostomy. This would relieve the back pressure and so prevent the spread of infection into the pancreatic duct.

PATHOLOGY

The liver in cases of the type we have described usually is swollen and large. It varies from yellowish to greenish black in the more severe cases. If the lesion is of the milder type and of long standing, the liver shows a marked increase in the interlobular con-

Fig. 14—A and B show the continuous chromic catgut sutures used in making the inner layer of the anastomosis between the common duct and the duodenum. C and D show an outer row of Lembert's interrupted silk sutures making an inversion of the common duct into the duodenum and completing the anastomosis.

enterostomy was performed as we felt that the fistulous tract would not permit regurgitation of bile. The patient recovered, and eight years after operation is well.

This is an excellent example of the tremendous damage that can be done to the liver by chronic obstruction of the common duct due to a local inflammatory process involving the lower end of the duct and the papilla of Vater.

Another patient, a woman aged 56 had deep jaundice with hemorrhage from the bowel and vomiting of coffee ground blood so severe that she became semicomatose. Twenty-six years earlier she had had two severe hemorrhages, and since that time had had repeated attacks of pain in the upper part of the abdomen on the right side with marked lassitude and

nective tissue, which varies from that of a mild cirrhosis to that of a hob-nailed liver. Histologically, besides the increase in the connective tissue, there are marked vacuolation and destruction of the liver cells, which, in some of the cases, gives a microscopic picture similar to that of subacute yellow atrophy (fig 9) (figs 7, 8 and 9).

A section of liver taken at operation in a critically ill patient on whom a choledochoduodenostomy could not be performed but on whom a drainage of the common duct was done showed marked degeneration of the liver cells and interlobular cirrhosis (fig 10). After five weeks of drainage the patient died. At autopsy a section of liver showed marked regeneration of the liver cells and the formation of new bile ducts (fig 11), proving that, in this condition, relieving the intraductal tension by anastomosis of the common duct and duodenum has a curative effect.

The pancreas varies from a medium hard, lobulated type to a hard, swollen type. In several cases, there was marked peripancreatitis in which the omentum of the lesser curvature of the stomach was tightly adherent to the capsule of the pancreas (fig 12).

TECHNIC OF OPERATION

The technic of anastomosis of the common duct and duodenum is as follows:

The gallbladder, which was inflamed in all of our cases, is removed in the usual manner. The site for the choledochoduodenostomy should be at the point where the common duct is attached to the duodenum, the peritoneal covering and loose areolar tissue acting as the base for the anastomosis.

Interrupted, fine, waxed silk sutures of the Lembert type are used to attach the broad surface of the common duct to that of the duodenum (fig 13 A). A curved incision with a small "y" at each end is made transversely across, or obliquely to the duct, and a slightly curved incision into the duodenum (fig 13 B).

The medial portion of the cut end of the muscularis and mucosa of the duodenum is then sutured to the medial cut end of the duct, using 0000 twenty day chromic catgut and continuous sutures, and starting in the middle of the posterior wall with a simple oblique over and over suture as in a gastro-enterostomy (fig 14 A and B). An outer row of Lembert's interrupted silk sutures are then brought through the common duct and duodenum to produce an inversion (fig 14 C and D).

The free edge of the attached omentum is then brought over the entire anastomosis and sutured onto it so as to prevent leakage of bile, the omentum seals it off quickly. The omentum is sutured down with interrupted silk sutures (fig 15 A). The inversion of the second row of Lembert's sutures and the flap of the transverse incision produce a one-way valve type of anastomosis as shown on cross-section (fig 15 B and D). A typical posterior gastro-enterostomy well over to the left side of the stomach is performed, as in figure 15 C.

The gastro-enterostomy, we believe is of great importance, it not only prevents the bryum meal from passing through the anastomosis of the common duct and duodenum up into the hepatic ducts but it throws the processes of digestion to the left and puts the duodenum, liver and pancreas at physiologic rest, or at their lowest physiologic limit. It accomplishes this by allowing the peristalsis of the duodenum and preventing chemical and mechanical irritation by food, which passes for the most part, through the gastro-enterostomy. We lay great stress on this point because as we have stated, the probable underlying etiologic factor that produces the spasm, edema and infiltration of the common duct and papilla of Vater is a triangular infection which starts in the duodenum as a duodenitis and then ascends through the papilla of Vater up the hepatic and pancreatic ducts. The effect of the gastro-enterostomy can be compared to the healed duodenum and ulcer observed when one is doing a subtotal gastrectomy for gastro-jejunal ulcer from a previous gastro-enterostomy.

COMMENT

Some observers may contend that the infection in these cases has its origin in the gallbladder. Yet in most of our cases the inflammation in the gallbladder seemed mild as compared with that in the lower end of the common duct, and it was our impression that the latter furnished the real pathologic process and that the infection must have had its origin there rather than in the gallbladder. Therefore, to relieve it, we anastomosed the common duct to the duodenum and performed gastro-enterostomy in preference to depending on cholecystectomy and drainage.

Some of the patients on whom we performed choledochoduodenostomy and gastro-enterostomy might have recovered with simple drainage of the common duct,

Fig 15—A shows the omentum sutured down with interrupted silk sutures so that it covers the anastomosis. B shows a transverse section of the inversion of the common duct into the duodenum. C shows the relationship of the new opening to the papilla of Vater. D shows the gastro-enterostomy placed well over to the left and the choledochoduodenostomy.

or with no operation. We contend, however, that it is more conservative to do one operation that cures, as shown in this series than to do three, in the third of which one has to do what should have been done at first.

CONCLUSIONS

1 Cases of chronic biliary stasis of the types that we have described are caused by a triangular infection of the duodenum, pancreas and common duct. The infection probably begins as duodenitis and ascends the common duct. It produces infiltration and swelling of the ampulla of Vater and of the lower portion of the common duct and thereby causes spasm and

obstruction of the papillary outlet of varying intensity. A vicious circle is established between the chronic infection and the chemical irritation caused by the stasis and back pressure of bile which produces degeneration and vacuolation of the liver cells and interlobular and periductal cirrhosis.

2 A perfect example of such chemical irritation in the liver occurs as the result of congenital obstruction in the common bile duct of the new-born.

3 There is a probability that cirrhosis of the liver in the greater number of cases is due to this type of infection rather than to a constitutional condition or to intrahepatic causes.

4 Attacks simulating gallstone attacks, are in some cases, due to obstructive spasms of the common duct.

5 All patients with chronic jaundice should have the benefit of exploration. This should not be deferred too long since the breakdown of the liver may go beyond the point of recovery, as shown in ten cases in which recovery did not take place after drainage.

6 Gastro-enterostomy is an important addition to choledochoduodenostomy because it prevents the regurgitation of food through the anastomosis between the common duct and the duodenum and puts the triangle of the duodenum, pancreas and hepatic ducts, which are the seat of this infection at rest.

7 Most of these patients with chronic obstructive jaundice can be cured by choledochoduodenostomy and gastro-enterostomy when performed in time as shown by the mortality of two deaths in our twenty-two cases.

8 Patients with recurrent multiple small stones in the common duct are best operated on by choledochoduodenostomy and gastro-enterostomy.

9 A follow-up of the cases in which we performed choledochoduodenostomy and gastro-enterostomy shows ten of the twenty patients to be still living and well. Two have died of pneumonia and one of coronary sclerosis. The remaining seven we have lost track of.

ABSTRACT OF DISCUSSION

DR J. TATE MASON, Seattle. The late Dr. John B. Murphy called my attention to the fact that patients with cholangitis, duodenitis, pancreatitis or constriction of the common duct causing jaundice were relieved by prolonged drainage of the common duct. This was done by placing a T-tube in the duct and leaving it in place for many months. Undoubtedly the neuromuscular nerve supply of the duct plays a very important role in biliary stasis. The parasympathetics which supply the propulsive action of the duct and the sympathetics, which control the ampulla of Vater, may have great influence through reflex action on both these structures as well as have inflammatory conditions in and around the duct. The reason patients with common duct disturbances causing jaundice have external drainage performed frequently and not an internal drainage such as Dr. Strauss has suggested in his choledochoduodenostomy is that anastomosis between the biliary system and the stomach or the duodenum invariably leads, if the anastomosis works and the patient lives long enough to an ascending infection, followed by hepatitis, cirrhosis and finally multiple abscesses of the liver. It is encouraging to learn from this study of Dr. Strauss that a gastro-enterostomy which diminishes intragastric and intraduodenal tension not only arrests this infection but prevents the splashing up as he says of the duodenal contents into the common duct and prevents this ascending infection. Many of these patients are poor surgical risks and if one has to do a choledochoduodenostomy and then a gastro-enterostomy the operation may be so prolonged that some immediate postoperative complication may occur. For some years I have used a simple method that I devised of anastomosing the common duct to the duodenum. Sometimes because of lack of exposure dense adhesions or a duct that

is not very large this anastomosis is prolonged and may be very difficult. As soon as the common duct is exposed just above the duodenum two traction sutures are placed between the duodenum and the duct on each side. With these, because the duct is always deep down and rather hard to expose, one can make a transverse incision in the duct and also a stab incision in the duodenum, then by pulling up on these sutures it is very easy to put in the posterior line of sutures. I now select a rubber tube 5 cm. long and about the size of the common duct and place a suture at the middle. This tube is then inserted into the opening, one end into the common duct and the other into the duodenum, and the traction sutures are cut off but with the suture in the tube there is still something to tug on. By tugging gently on this I now sew up as closely round this ligature as possible. After the incision is sutured up completely round the tube, the traction suture is cut away and to keep the rubber tube from staying too long in the anastomosis, at the close of the operation it is pushed down into the duodenum approximately two thirds of its length, it being quite easy to feel the tube through the anastomosis. This anastomosis can be done in from five to twelve minutes. With this method of anastomosis of the common duct to the duodenum, in many instances a gastro-enterostomy will be possible, whereas otherwise the two procedures would take too much time. If these patients are to be operated on I should not wait until there is much damage to liver tissue or until the liver takes up two thirds of the abdominal cavity. It should be done as early as the diagnosis can be made.

DR. WALTER WATERS, Rochester, Minn. In talking with Dr. Strauss I found that we both were emphatic in our decision that this procedure is indicated in relatively few cases of obstruction of the common bile duct, because in most cases there is a demonstrable cause for the obstruction. In order of frequency such obstructions are caused by the following: stones in the common bile duct, inflammation in the gallbladder which has extended by continuity into the common bile duct, the pancreas and the hepatic ducts, papillomas, adenomas or carcinomas of the ampulla of Vater and the relatively rare ulcers on the posterior wall of the duodenum which have perforated into the pancreas producing the severe colic that is associated with biliary colic and occasionally producing so much inflammation and edema in the pancreas that the common bile duct is slightly constricted and the patient slightly jaundiced. Therefore if Dr. Strauss's cases are considered in groups, the group in which the procedure is most satisfactory. I am sure all will agree is that of cases of tumor in the head of the pancreas that produces painless jaundice. Such a group constituted half of Dr. Strauss's series. The tumors are chiefly carcinomas. In my experience approximately 15 per cent of tumors obstructing the pancreatic portion of the common bile duct are inflammatory, and it is very difficult to distinguish at the time of operation between the two types of enlargement of the head of the pancreas. Certainly the relief of obstruction by anastomosis between the distended gallbladder or common bile duct and the duodenum or stomach will prolong the patient's life. If carcinoma is the cause of the obstruction the patient is relieved of the jaundice and the intense pruritus although eventually he will die of the lesion. In many of these cases later, a gastro-enteric stoma will have to be made to relieve the obstruction caused by the mechanical encroachment on the duodenum by the enlargement of the tumor in the head of the pancreas. Therefore if the surgeon feels that the condition of the patient is such that both procedures can be carried out at one operation such a decision is wise. In the first group of eight cases approximately a fourth of Dr. Strauss's cases the patients had biliary colic without jaundice. Treatment was conservative, the diseased gallbladders were removed, the ducts were opened and drained and in four of his cases the colic recurred. Following the procedure that he has suggested, namely, anastomosis of the duct to the duodenum the patients were relieved. I differ with Dr. Strauss's decision relative to the second group. In these cases there is inflammation in the gallbladder associated with jaundice, thickening in the head of the pancreas and infection of the bile. I believe that in these cases the jaundice is the result of the inflammation starting in the gallbladder and extending to the common bile duct, the pancreas and the liver and that removal of the gallbladder and drainage of the com-

mon bile duct by a T-tube, a much less potentially serious surgical procedure, will relieve the patient in the majority of cases

DR ALFRED A. STRAUSS, Chicago I agree with everything that Drs Mason and Walters have said except with that difference that it still has to be decided whether this is a triangular infection

SUCCESSFUL REMOVAL OF AN ENTIRE LUNG FOR CARCINOMA OF THE BRONCHUS

EVARTS A. GRAHAM, MD

AND

J. J. SINGER, MD

ST. LOUIS

Carcinoma of the bronchus in recent years has become a problem of major importance. It is now known that primary carcinoma of the lung, which almost always arises in a bronchus, constitutes between 5 and 10 per cent of all carcinomas.¹ In frequency, therefore, it is comparable with carcinoma of the large intestine and it is much more frequent than the malignant tumors of some other organs that have received much more comment. The problem of primary carcinoma of the lung is of special importance, since up to the present time at least the prognosis has been almost uniformly bad because of the complete futility of any methods of treatment other than surgical excision. There is no record in the literature of the successful treatment by radiotherapy of a single case in which the pathologic evidence has been incontrovertible and in which a five year interval without recurrence has elapsed between the treatment and the time of reporting the case, despite the fact that many cases have been treated according to the most modern methods of using both x-rays and radium. It would seem, therefore, that unless some entirely new general principle in the treatment of carcinoma is devised, the only method that at present can offer any hope is the wide surgical removal of the tumor and the surrounding tissue.

In a recent extensive review of the literature, Carlson and Ballou² of the Barnes Hospital have discussed the reported cases in which surgical removal has been accomplished or attempted. In all there are apparently six cases in the literature in which a patient has survived the surgical removal of the carcinoma and has been well at the time of the report a year or more later. Two of these patients were operated on by Sauerbruch,³ one by Churchill,⁴ two by Tudor Edwards⁵ and one by Allen and Smith.⁶ In these reported cases only a limited removal of lung tissue has been performed amounting however in most cases to the removal of one lobe of the lung. In Churchill's case the lower and middle lobes of the right lung were removed. There have also been six cases reported in which malignant tumors of the bronchi have been removed by means of the bronchoscope. In practically all the latter cases however there is no evidence that survival has extended beyond one year. The case about

to be reported is apparently the first one in which an entire lung has been successfully removed for a carcinoma. In fact, it is apparently the first time in which the whole lung has been deliberately removed at one stage. It is possible that Kummell⁷ removed the whole lung for a carcinoma, but the description of the case is so meager that it is difficult to be sure. At any rate, the patient died. There are two instances in which an entire lung has been removed for bronchiectasis, one by Nissen⁸ of Berlin and the other by Haight⁹ of Ann Arbor, Mich. In both the latter cases, however, the lung was allowed to slough out after ligation of the hilus. It seems particularly important to call attention to the fact that an entire lung has been successfully removed for carcinoma of the bronchus because if this should prove to be a feasible operation in properly selected cases it is probable that many patients would be saved who otherwise would die of carcinoma.

REPORT OF CASE

J. L. G., a man, aged 48, a physician, admitted to the Barnes Hospital, Feb. 27, 1933, had had repeated attacks of cough and fever with pain in the left side of the chest for a period of

Fig. 1.—Carcinoma obstructing the bronchus of the left upper lobe. A, atelectasis of the left upper lobe with the surrounding pneumothorax. B, after removal of the entire lung and all but the first two ribs. The air-tight catheter leading to the stump of the bronchus is seen. C, drainage of the empyema cavity that was caused by leaving the first two ribs in place. D, at time of discharge from the hospital and after the removal of the first two ribs, the empyema cavity is completely obliterated and the wounds are solidly healed; the trachea is in the midline.

seven months. Other complaints were loss of weight and general lassitude. In January, 1929, he had a pneumonia of the lower lobe of the right lung (the other lung). The pneumonia in the right lung was said to have spread and to have involved the entire lung. After several weeks, however he stated that he recovered fully from the attack of pneumonia until his symptoms appeared insidiously in the left lung more than three years later.

In July, 1932, he complained of malaise with chilly sensations and a temperature of 104 F. At that time nothing was found on physical examination to explain his symptoms. The leukocytes numbered 17,000. August 11, a roentgen examination revealed a fan-shaped shadow with the base outward in the region of the left axilla. By August 20, his symptoms had subsided and the x-ray shadow had become smaller. October 7 he had a repetition of his former symptoms with a return of the former x-ray shadow. These symptoms subsided in a few days but recurred again about October 20. At this time there was some dulness, and a diagnosis either of interlobar empyema or of lung abscess was made. When an attempt was made to aspirate pus, December 5, a pneumothorax developed, after which a marked improvement in his symptoms was noted although there was a complaint of some pain in the left side of the chest. Artificial pneumothorax was then continued and the patient showed steady improvement until ten days before his admission to the Barnes Hospital (Feb 17, 1933) when he had a recurrence of fever and discomfort. At no time was there any actual pain and never any bloody sputum.

Fig 2—Diagram of lung showing (A) location of the tumor in the bronchus of the upper lobe but extending so far medially as to project slightly into the bronchus of the lower lobe. For this reason it was impossible to attempt to save the bronchus of the lower lobe. The location of numerous small abscesses is also seen on the diagram as well as the incomplete interlobar fissure.

The patient was of medium build with a suggestion of loss of weight and a rather pale complexion. The left side of the chest moved less than the right, and the breath sounds were diminished or absent on that side. A roentgen examination showed the left upper lobe to be atelectatic with pneumothorax present. The lower lobe seemed to be fully expanded and adherent to the chest wall. The blood examination showed 4,800,000 red cells, 11,500 leukocytes and 85 per cent hemoglobin. Because of the presence of the atelectasis of the upper lobe and in view of the patient's history of an insidious onset, a diagnosis was made of an obstruction of the bronchus of the upper lobe probably by a tumor. Bronchography with iodized oil substantiated the diagnosis of obstruction of the bronchus of the left upper lobe. A bronchoscopic examination was accordingly advised and performed by Dr Arbuckle March 1. At this time tissue was removed which seemed microscopically to be only granulation tissue. The patient's symptoms improved following this examination because the obstruction of the bronchus had been somewhat relieved. A bronchoscopic examina-

tion was repeated on March 14 and again on March 21, at which specimens were removed again at both examinations. Both of these specimens revealed a squamous cell carcinoma of the bronchus. The patient was advised to have the left upper lobe removed because of the presence of the carcinoma obstructing the bronchus of that lobe.

Fig 3—Mesial aspect of lung after removal. The main bronchus of the lower lobe (A) has been split open. The tumor (B) is seen projecting from the bronchus of the upper lobe.

Fig 4—Specimen obtained at biopsy through a bronchoscope.

At the operation, however, which was performed, April 5, with intratracheal anesthesia of nitrous oxide and oxygen, it was found that the carcinoma extended so closely to the bronchus of the lower lobe that it was impossible to save the latter bronchus. Moreover there were many nodules in the upper portion of the lower lobe about which uncertainty existed as to whether they were tumor tissue or areas of inflammation.

Finally also the interlobar fissure was not complete. For all these reasons it was decided to remove the entire lung. The adhesions between the lower lobe, chest wall and diaphragm were separated without great difficulty. A small rubber catheter was tied tightly around the hilus as close to the trachea as possible. Crushing clamps were placed on the hilus below the catheter and the lung was cut off with an electric cautery knife. The open end of the left main bronchus was carefully cauterized with the actual cautery as far up as the catheter would permit in order to destroy the mucous membrane thoroughly. A transfixing double ligature of number 2 chromic catgut was tied around the stump just distal to the catheter and the latter was then removed. No bleeding occurred. Another transfixing ligature of number 2 chromic catgut was placed where the catheter had been. The stump of the pulmonary artery was then ligated separately with catgut, and seven radon seeds of 15 millicuries each were inserted into various parts of the stump. Several enlarged tracheobronchial glands were removed from the mediastinum, and seven ribs, from the third to the ninth, inclusive, were removed from the transverse processes of the spine to the anterior axillary line. The ribs were removed for the purpose of allowing the soft tissues of the chest wall to collapse against the bronchial stump and therefore to obliterate as much as possible the pleural cavity. The first and second ribs were not removed at this time merely because it was desired not to do too much

both from the previous accumulation of air in the unobliterated portion of the cavity and also because the patient was coughing up pus, that there was a small communication between the unobliterated portion of the pleural cavity and the bronchial stump. After about two weeks the drainage tube slipped out of the cavity and was found on the dressings. The wound had healed sufficiently so that it was difficult to replace the catheter. It was therefore decided to reestablish drainage anteriorly

Fig 6—Section through the wall of the bronchus about 0.5 cm mesial to the tumor. There is no evidence of carcinoma at this place. Evidently therefore, the tumor was confined to its original location.

Fig 5—Specimen obtained from the tumor after removal of the lung. A careful examination of many slides showed the bronchial cartilage everywhere to be intact.

operating at once. Nevertheless it was felt that there would be some danger of the development of an empyema in the upper part of the pleural cavity because of the failure to obliterate that space. The wound was closed tightly, but provision for drainage was made by the use of an air tight catheter brought out through a stab wound.

The patient left the operating room in excellent condition but was nevertheless given a transfusion of 500 cc of blood. The closed drainage yielded about 800 cc of serosanguineous fluid during each of the first two days. After that period the drainage rapidly diminished and practically ceased on the fifth postoperative day. The catheter was gradually withdrawn. The wound healed by primary intention. There was surprisingly little immediate postoperative reaction of any kind except for a moderate amount of dyspnea on exertion and deep seated pain in the back which was controlled with opiates. On the ninth postoperative day there was a collection of air and pus in the extreme upper portion of the pleural cavity. The rest of the pleural cavity was completely obliterated by what seemed to be solid healing of the soft tissues of the chest wall against the mediastinal pleura. The small empyema cavity in the upper part of the thorax was drained through a stab wound made posteriorly just below the second rib. It was evident

in order to have the back free from infection when the first and second ribs should be removed. A small drain, therefore, was placed through the first interspace, anteriorly, for a few days. The patient's temperature and pulse had been normal during the entire time of the drainage of the empyema cavity. May 22, through a posterior incision, the first and second ribs were removed in almost their entire length. There was almost no reaction after this operation. The small remnant of pleural cavity was completely obliterated at once.

The pain in the back subsided and within three weeks the wounds were all solidly healed. The patient's strength gradually increased, his appetite was excellent and he was discharged from the hospital, June 18, looking and feeling better than he had for many months previously. His only complaint was some dyspnea on exertion, but he had been walking about

Fig 7—The patient at time of discharge from the hospital. The wounds are solidly healed and he has good movement of the left arm.

the hospital for two weeks before his discharge. His vital capacity on admission was 3500 cc. at his discharge it was 1650 cc. Also at the time of discharge an examination of the blood showed 5,100,000 red cells, 8,500 leukocytes and 90 per cent hemoglobin. An electrocardiogram was essentially normal and a roentgen examination showed the left pleural cavity to be completely obliterated. A report received from him July 25 five weeks after his discharge stated that he had gained 8 pounds (3.6 kg.) at home that he was able to walk

about a mile without much dyspnea, that he was driving his automobile and that his strength was rapidly improving. The dyspnea was rapidly becoming less.

COMMENT

The examination of the lung after its removal was encouraging, because it showed no evidence of any extension of the carcinoma beyond the original site. The whole tumor measured only about 1 cm in the long diameter, but it was situated almost at the bifurcation of the main bronchus into the bronchus of the upper lobe and that of the lower lobe. The nodules, which had been felt in the lung at operation, were small abscesses that showed no evidence of carcinoma on microscopic examination. Likewise, the enlarged tracheobronchial glands, which had been removed from the mediastinum, showed no evidence of carcinoma. The tumor itself was definitely a squamous cell carcinoma. A feature of it, which is probably important, was that it had not invaded the bronchial cartilage. By analogy with what is well known concerning carcinoma of the larynx, the failure of the tumor to invade the bronchial cartilage in this case would seem to be of excellent prognostic significance.

Several features about this case warrant special comment. In the light of the experience derived from this first case of complete removal of a lung, together with many of the mediastinal tracheobronchial glands, for carcinoma, the operation would seem to be one that is entirely feasible in properly selected cases. Just as experience with carcinoma in other parts of the body has taught that the number of cures is, in general, directly proportional to the extent of radical removal, so it may be inferred, perhaps, that if the entire lung is removed the patient will have less chance of a recurrence than if only one lobe or a smaller portion is removed. In order, however, to have a creditable number of successes, surgeons who are properly qualified by experience in this special field to perform such an operation must receive the patient before extensive metastases have occurred. There is now little excuse for the common failure to diagnose a carcinoma of the bronchus in its early stages. Certainly the majority of such tumors can be diagnosed before demonstrable metastases have occurred.

Another feature of peculiar interest in this case is that, despite the fact that the hilus of the entire lung was suddenly shut off by a tight ligature, none of the signs or symptoms of pulmonary embolism appeared. The sudden obstruction of the pulmonary artery of the left lung by the ligature was analogous to the sudden obstruction of it by an embolus. Nevertheless, not the slightest change in the character of the patient's respiration could be noted immediately following the application of the ligature. Possibly the fact that he was receiving intratracheal anesthesia was of importance.

SUMMARY

The left lung and many of the tracheobronchial mediastinal glands were removed in a one stage operation because of a carcinoma that originated in the bronchus of the upper lobe but which was so close to the bronchus of the lower lobe that, in order to remove it completely, it was necessary to remove the entire lung. This is apparently the first case in which an entire lung has been removed successfully at one stage.¹⁰
600 South Kingshighway

10 A letter from the patient written on Sept. 19, 1933, four and one half months after the operation, states that his weight has increased by 16 pounds (7.3 kg.) since leaving the hospital and that he is constantly gaining in strength and energy.

TORUS FRACTURES OF THE LOWER EXTREMITY OF THE FOREARM IN CHILDREN

CARL L. GILLIES, M.D.

CEDAR RAPIDS, IOWA

Torus or folding fractures (Stauchungsbruch, par tassement) of the lower extremity of the forearm is the most common bony injury of childhood.¹ It is characterized by a localized expansion or torus of the cortex accompanied by very little or, in some cases, no displacement of the lower end of the bone.

These fractures have long been recognized. Thore, in 1844, was first to collect observations, which he supplemented with studies on cadavers. De Quervain,² Iselin,³ Vulliet,⁴ Burnham,⁵ Troell,¹ and many others have studied and written of this type of fracture. In spite of this fact, these injuries are not generally understood and are not discussed in most textbooks devoted to the study of fractures.

Fig. 1—Torus fractures of both bones with slight posterior tilting of the distal fragments.

These bony injuries are of importance, first because of their extreme frequency and, secondly, because they are true fractures, as evidenced in late cases by the production of callus. They cannot be considered important from the standpoint of prognosis, as they are the least serious of all true forearm fractures.

A fall on the outstretched arm, the hand striking the ground in dorsiflexion, is usually the method of production. A longitudinal compression or thrust force is exerted on the radius first and then on the ulna if the force continues. The long bones of the forearm in children may be likened to and, in fact, are hollow.

Read before the Section on Radiology at the Eighty-Fourth Annual Session of the American Medical Association, Milwaukee, June 16, 1933.

elastic tubes surrounded by a relatively tough membrane, the periosteum, the lower end being strengthened by an increase in circumference and by the presence of cancellous bone

In the production of these fractures, the cylindrical shaft is compressed in a longitudinal direction, and the diameter is enlarged at the expense of the length, as evidenced by a localized bulging or torus followed by a bending or flexion. The fracture occurs in the weakest portion, which is near the junction of the diaphysis with the metaphysis, a point relatively higher than the classic wrist fracture in adults. Most frequently the posterior surface (fig 1) but in a minority of cases the anterior surface (fig 2) shows the greatest bulging, and the upper portion (diaphysis) may encroach on the medullary canal. In either case both the mesial and lateral surfaces, at the same level, will show some degree of bulging. These are not greenstick fractures in the true sense of the word. If the force continues, the cortex opposite the greatest torus gives way, accompanied by an increase in deformity, and the fracture may become complete. Likewise, whether one or both bones is involved depends on the character of the force received.

Clinically, the diagnosis of torus fracture is made by

- 1 Reluctance on the part of the child to use the extremity following a fall on the outstretched forearm
- 2 A localized swelling located from $\frac{3}{4}$ to $1\frac{1}{2}$ inches above the wrist
- 3 "Wincing" tenderness on pressure confined to the bone directly beneath the area of swelling
- 4 Mild deformity not present in all cases
- 5 Absence of crepitus

The diagnosis should always be confirmed by roentgen examination

Doubtless, many of these cases would show good results without any treatment whatever. It is advisable, however, for the protection of the attending physician, to use splints in all cases and this for two reasons. First, the lay mind does not distinguish between the different types of fractures, and, secondly, as children are subject to frequent falls, a subsequent injury might easily complete the solution of continuity in a bone already weakened by a torus fracture. If deformity is present, this, of course, should be corrected. It may be necessary to complete the fracture as the deformity tends to recur because of the elasticity of the bones in childhood. A well padded posterior splint or preferably a posterior plaster mold should be applied for a period of two or three weeks. This, of course, may and should be removed at frequent intervals for physical therapy.

In the past three years I have collected a series of seventy-five selected cases of torus fractures. Complete fractures of one or both bones are not included in this group even though visible cortex torus was present. That is, cases are not included in which in addition to a longitudinal compression, there has been sufficient flexion, torsion or wrenching to complete the fracture.

Of these seventy-five cases forty-four occurred in boys and thirty-one in girls. The age incidence varied from 3 to 15 years, the average being 10.5 years.

The radius alone was fractured in fifty-three cases and both bones were fractured in twenty-two. In no case was the ulna alone fractured.

The fracture site varied from $\frac{1}{2}$ to $1\frac{1}{2}$ inches above the wrist, the average being $1\frac{1}{10}$ inches. This is in all cases relatively and in most cases actually higher than

the site of classic fracture in adults, which usually is three-fourths inch above the wrist.

An interesting observation, and one that I am unable to explain, is the difference in the observations made in the two sexes, in forty-one of the forty-four boys the greatest torus was on the posterior surface and the displacement, if present, was a posterior tilting of the distal fragment (fig 1). In only three cases was the reverse or the greatest torus seen on the anterior surface, and the displacement, if present, was an anterior tilting of the distal fragment (fig 2).

On the other hand, of the thirty-one fractures in girls, in only fourteen was the greatest torus on the posterior surface and the displacement, if present, was a posterior tilting of the distal fragment (fig 1). In seventeen cases the greatest torus was on the anterior surface and the displacement, if present, was an anterior tilting of the distal fragment (fig 2).

Fig. 2.—Torus fractures of both bones with slight anterior tilting of the distal fragments

SUMMARY

- 1 Torus fractures of the forearm are of importance because of their extreme frequency
- 2 The fracture site is always relatively and in most cases actually higher than the site of classic fracture in adults
- 3 In boys, the greatest torus is practically always on the posterior surface and the displacement, if any, is a posterior tilting of the distal fragment
- 4 In girls the incidence of the two types is nearly equal

120 Third Avenue S. E.

ABSTRACT OF DISCUSSION

DR. PAUL C. HODGES, Chicago: Dr. Gillies probably had to pick the most gross lesions in order to be able to demonstrate them on lantern slides. I suppose that he sees many cases in which the changes are so slight that they are overlooked unless one examines his films carefully. Dr. Walter Sullivan of the department of anatomy, University of Wisconsin, makes bromide enlargements of roentgenograms of bone and by this means is able to see a surprising amount of the detail

of the cancellous structure. To some extent, of course the use of a reading glass for the direct examination of the original films accomplishes the same purpose, but I believe that Dr Sullivan's method is even better and that it might be applicable to the study of clinical roentgenograms, in a condition like the one that has just been presented. The pelvic fractures occurring in the osteomalacia of child-bearing women bear some resemblance to torus fractures, because in that condition the bones have certain features in common with the bones of very young children. Such fractures are so different from the ordinary fracture of adult bone that they are sometimes described as crumpling rather than fracture. When Dr Hollis E. Potter makes roentgenograms of a wrist, he makes a number of views on each film, as a routine, including only a small part of the extremity but turning it into a variety of positions. He can do this, of course, only when he has definite information sent to him by the referring physician or obtained by his own physical examination, but when such information is available it is not necessary to make large general purpose views. A technic of this sort ought to be valuable when one suspects a torus fracture that might show up only in a particularly fortunate arrangement of bone in relation to tube and film.

OSTEOTOMY FOR FLEXION DEFORMITY AT THE HIP DUE TO ANTERIOR POLIOMYELITIS

EDWIN W. RYERSON, M.D.
CHICAGO

Contracture of the hip in flexion and abduction is a common deformity in cases of infantile paralysis. The resulting disability is so severe and so difficult to relieve that open operation is always necessary in cases of long duration. It is with regard to the operative technic that this paper has been written.

The contracture is caused primarily by a shortening of the tensor fasciae femoris, but in the course of time

Fig. 1—Method of locomotion for eighteen years

the gluteus medius, the iliopsoas and the rectus femoris become shortened, as do even the iliofemoral ligament and the capsule.

As in most poliomyelitic deformities prevention is less difficult than cure. While the child lies in bed during the early stages of the attack of infantile paralysis, the easy and comfortable position is with the

thighs widely abducted and the knees flexed. This is the worst possible position, because it allows the tensor fasciae latae and the thigh flexors to become contracted, and by reason of the very short leverage afforded by the pelvis, it is practically impossible to correct the deformity by conservative measures when it has once become established. If, however, the legs are held parallel in the beginning, by plaster casts or by pinning towels around the legs, the contracture may ordinarily be prevented.

Fig. 2—Another view of patient in locomotion (enlarged from a 16 mm. moving picture film)

Considering now those patients with a severe and intractable deformity, what can be done for their relief? Traction in any form is useless, even when made in the line of deformity, with the leg elevated and the pelvis flat on the bed. Open division, by Soutter's method, is successful in young children, the tensor fasciae and the gluteus medius being peeled downward from the crest and from the anterior superior spine of the ilium, but this operation requires a long and difficult after-treatment and sometimes causes considerable shock.

In older patients, Campbell's ingenious transference downward of the iliac crest and its externally attached muscles is very effective, but when, in addition, it includes division of the iliopsoas tendon, the capsule and the Y-ligament of Bigelow, it becomes questionable, in my opinion, whether or not such important structures should be sacrificed.

This problem presented itself in the following case.

A woman, aged 29, had a right-angled flexion contracture of both hips, bilateral genu recurvatum and equinovarus of the left foot. There was very little power in any muscles below the hips. For eighteen years she had been obliged to walk on all fours like a quadruped. Braces had been tried but could not be used successfully. She entered St. Luke's Hospital Nov. 23, 1931, and on November 25 the right iliac crest was displaced downward by Campbell's method, but without dividing the iliopsoas or the capsule. Three weeks later a similar operation was done on the left hip. A considerable reduction of the deformity was attained, but the thighs still remained flexed at an angle of 45 degrees in spite of heavy traction.

An oblique subtrochanteric osteotomy was performed six weeks later through a small incision and immediately the femur dropped readily into perfect correction. The postoperative discomfort was very much less than after the former procedure and the after-care was simple. A few weeks later the opposite femur was likewise divided, and, although the

position of the fractured surfaces was not quite so satisfactory, the result was equally good. The equinovarus of the left foot was corrected by a triple arthrodesis, at the time of the second osteotomy, with a tenodesis of the tibialis anticus tendon.

The patient was discharged from the hospital, Aug 18, 1932, walking fairly well with long braces and crutches. I examined her, June 8, 1933. She is able to walk well with the braces and crutches and does her own housework. The extreme lordosis of the lumbar spine has disappeared. She can advance both thighs strongly by the action of the iliopsoas muscles. It will be advisable, at some future time, to perform a bone-block at the knees, to correct the genu recurvatum, after which she may be able to walk without braces.

CONCLUSION

I believe that in the class of cases here discussed it is wise to displace downward the origins of the tensor fasciae latae and the gluteus medius muscles, and perhaps also to cut transversely the iliotibial band. If this does not produce sufficient correction, I believe that it is not wise to divide such important structures as the capsule of the hip joint and the iliopsoas muscle, and that it is distinctly preferable to perform an osteotomy in the upper portion of the femur, either at the same sitting or at a later date.

122 South Michigan Avenue

ABSTRACT OF DISCUSSION

DR J S SPEED, Memphis Tenn. With the average mild flexion contracture of the hip, the Soutter operation was satisfactory, but for these extreme flexion contractures of the hip it was insufficient and it was for just this type of case that the operation for the transference of the crest of the ilium was worked out by Dr Campbell. It has been possible to correct by this operation practically all even the extreme types of flexion contracture of the hip. I am in accord with Dr Ryerson regarding some type of bony

Fig. 1.—Patient using crut lies and braces after operation

operation in cases that cannot be corrected by operations on the soft parts alone. I believe that the more experience one has with the extensive soft tissue operations, the less necessity will be there for bony operations. In some cases, however, an osteotomy as described by Dr Ryerson is necessary. I have performed such osteotomies in several cases with most satisfactory results. The necessity for osteotomy, however, will be rare if a complete division is made of the contracted structures that prevent correction of the deformity. The structures that produce the greatest resistance are in their order the median head of the quadriceps muscle, the muscle attached to the anterior-inferior spine, the capsule of the hip joint, and the psoas muscle. The median head of the quadriceps muscle is attached to the anterior-inferior spine by a broad tendinous band which in cases of paralysis appears as a dense fibrous contraction band very resistant in nature. It is frequently better to do a tenotomy through the tendon just below the inferior spine rather than to attempt to strip it off from its attachments. It is occasionally necessary to divide the anterior capsule of the hip joint where one has not seen any instability or increased loss of function of the hip following this. I rarely ever find it necessary or advisable to divide the psoas muscle and advise against the division of this muscle for two reasons: first the psoas muscle is rarely ever paralyzed and hence a living muscle can gradually be stretched; second

the psoas muscle is frequently one of the few active muscles left controlling the thigh. For this reason I do not wish to sacrifice its function if it can possibly be avoided. There is no question that the original Soutter operation, when it was being used to correct these severe deformities, was followed by a severe shock and in some cases death. I feel that the shock in these cases was due to too great a tension being placed on the undivided structures. The more extensively the contracted structures are divided surgically, the less tension and less shock following the operation. It is the tension and not the operative surgery that caused the bad results in such cases. I am in favor of a wide dissection and complete division of the contracted structures rather than a partial division with the resulting increased tension on the undivided structures when an attempt is made to correct the deformity.

DR JOHN O DIETERLE, Milwaukee. Dr Ryerson's procedure in doing a subtrochanteric or oblique intertrochanteric osteotomy in cases of this type is certainly very useful and will add to the correction of severe flexion deformities of the hip following poliomyelitis. A subtrochanteric or oblique osteotomy between the trochanters will most certainly facilitate the correction of these deformities. I recently had a case of severe abduction flexion deformity at the hip in a patient with arthritis. In this case, of course, an oblique osteotomy or subtrochanteric osteotomy is necessary before doing an operation on the soft parts. I first did the subtrochanteric osteotomy and then stripped down the soft tissues at the anterosuperior spine and in one operation was able to get a complete correction of the leg. I wish also to emphasize that the after-treatment in a case of this kind is much simplified. Every one knows the cumbersome and long drawn out treatment after the Soutter operation and the other stripping operations about the ilium. In this case I take it that Dr Ryerson simply applies a plaster spica and allows the repair to take place. I should like to ask Dr Ryerson a question on a point that I believe Dr Speed has already mentioned. After an oblique or subtrochanteric osteotomy isn't there some danger of pulling the upper end of the femur forward, displacing the fragments, and thereby endangering union at the upper end of the femur?

DR EDWIN W RYERSON, Chicago. The after-treatment following the muscle division has in my hands been extremely painful to the patient and has been so difficult in contrast to the after-treatment following the osteotomy that it has convinced me that if I were the patient I should much rather have a Soutter or partial Campbell operation and then the oblique osteotomy in the subtrochanteric region. This woman suffered greatly after the soft part operation and suffered practically none after the bone operation. The whole point of the paper is that if there are some good muscles and a good, strong capsule for the hip joint, I think it is not advisable to sacrifice a considerable part of the power of the remaining musculature and to a great extent of the capsule and Bigelow's ligament. There is not much deformity to be feared if the osteotomy is done high enough. If it is done a little too low there may be a good deal of deformity, and such was the case with this woman. The roentgenograms of the fracture taken afterward show a considerable malposition and yet she gets about perfectly well and is immensely relieved of her former deformity. The pull of these muscles after osteotomy is not very great and they do extremely well if one avoids interfering with the structure of the hip joint by dividing too much of the capsule. It is simply a suggestion and I think it may turn out to be worth while.

A Wider Point of View—Internists generally should take a broader view of their responsibilities in the study and treatment of disease than has become customary in recent years. Physicians of earlier times unsupported by specialization often exhibited a wider point of view and it is not an unmerited criticism of modern medicine to say that in delegating to specialists the entire management of conditions in which certain localized types of symptoms have arisen the physician not only neglects his proper duty to the patient but as similar experiences repeat themselves narrows his horizon of appreciation of the whole picture of disease.—Stengel Alfred. *The Internist as His Own Psychiatrist*. *Ann Int Med* 7:281 (Sept) 1933.

THE IMMEDIATE TREATMENT OF COMPOUND FRACTURES

THE ALBEE BONE GRAFT AND THE WINNETT ORR METHOD OF POSTOPERATIVE CARE

H WINNETT ORR, M.D.
LINCOLN, NEB

A study of the literature reveals that, on a number of occasions, surgeons have suggested direct fixation of the fragments by wire, pins or screws, in compound fractures at the time of injury. It has been the experience of all, however, that patients so treated have not done well, and, generally speaking, both in the colleges and in the textbooks the teaching has been that such attempts should not be made.

In the more serious compound fractures in which there is loss of substance, especially in the larger bones, the usual plan has been either to amputate at once or to allow healing to occur after a long course of treatment of the soft part wound, without much consideration having been given to the result from the

tory in some cases but sometimes, on account of scarring or infection, good results from late plastic procedures could not be obtained.

Since the adoption of my method for the postoperative treatment of such patients by infrequent dressing much better results have been obtained. More rapid healing and with less scarring has been the rule, and subsequent bone graft procedures have been more successful accordingly. Several times during the past few years it has been possible to obtain much earlier satisfactory results. These have been accomplished by plastic bone procedures of various kinds and by manipulations for the correction of deformity performed during the course of healing of the infected wound. While this has been contrary to my previous custom the patient has gone on to good healing, and I have thus been able to obtain earlier and better results in such cases.

A formal primary Albee bone transplant at the time of an open infected fracture was not undertaken until recently. I felt that since I had been so successful in preventing postoperative infectious complications and healing had been obtained so regularly in the absence of the bone graft, a similar result might be obtained with a bone graft present. It was obvious also that the ultimate result in such a case, if successful, would mean a shortening of the patient's stay in the hospital and a reduction of many months in the disability period. Early healing of the wound and repair of the fracture in this way would also have the effect of avoiding secondary surgical procedures and the danger of other infectious and deformity complications. Accordingly, such a procedure was undertaken in the case to be described.

A young man was injured in an automobile collision on a highway about 400 miles from Lincoln, Oct. 21, 1932. He was carried to the nearest hospital, a few miles away, where it was found that he had a very severe compound fracture of the left leg just below the middle third. A fragment of the tibia about 2½ inches long was entirely missing. The large opening in the soft parts was sutured but could not be entirely closed. Even with the leg short and with some angular deformity there was still quite a large opening over the fracture area. (The plan of attempting to close the wound with sutures and of depending on a rubber tube for drainage is one of the commonest errors in this kind of emergency surgery.) Following the suturing, the leg was put into a plaster cast extending from the toes to just above the knee. There was considerable shortening and deformity. Thirty-six hours later the patient was brought in an ambulance 400 miles to Lincoln, arriving at about 8 o'clock in the morning, October 23. He was given 5 per cent dextrose solution intravenously and antitetanus and anti gas bacillus serum. He was then taken to the operating room about 10 o'clock and the first aid cast removed. The cast and all the dressings were badly saturated with blood and the patient was still in moderate shock.

On the fracture table a pin was put through the calcaneum, and the leg was brought down to a straight line and full length. An additional pin was also placed through the upper fragment of the tibia. Then the entire leg was prepared for open operation. Sutures in the skin were removed and the fracture area was examined. It was found that the fibula was now in correct length and position; there was a gap of about 2½ inches in the tibia. There was not enough skin and soft tissue to cover the fracture area. The entire fracture region was infected but it was felt that a long heavy slide bone graft

Fig 1—An immediate Albee bone graft and the Winnett Orr method of postoperative care for a compound fracture of the leg with 2 inches loss of substance of the tibia. A appearance of the leg thirty-six hours after injury (Oct 22, 1932) on removal of the first cast and removal of the stitches used to close the original wound partially. B the leg has been pulled down straight and to full length by traction on a pin through the heel. The knee is supported in correct position by a sling and a supporting pin put through the upper fragment of the tibia. The slide graft has been carried down across the defect in the tibia and fastened in place. C with all the parts in good position the wound over the healthy bone is brought together with a single stitch at each end and the fracture area packed for open drainage with a nonantiseptic petrolatum pack. D without any movement or change of length or position all the parts including the traction pins are included in the cast. E condition at the time of the third dressing and change of cast. Wound practically healed and graft healing in. (This is from a photograph of soap models by Dr. Teal of Lincoln, Neb.)

standpoint of the fracture. There has usually been a shortened and deformed extremity to be treated secondarily by bone graft or by some other plastic procedure when that appeared to be feasible. In many prolonged cases with delayed healing of the wound and nonunion of the fracture, eventual amputation has been the final resort.

For many years it has been my practice to maintain all such injured extremities without regard to the amount of bone defect with the limb in the straight position and full length so that shortening and deformity could not occur during the period of wound healing. Later treatment by a bone transplant was satisfac-

from the upper fragment of the tibia might be brought across the bone defect and that it might contribute to the repair. Such a graft was obtained from the upper fragment. The lower end of the graft was driven into the medulla of the lower fragment. The upper end was fastened into the groove in the lower portion of the upper fragment by means of two chromic catgut sutures passed through drill holes. This gave considerable stability to the tibia as a whole. The extreme angles of the surgical wound were brought together with one stitch at each end, but the major portion of the wound was packed open with petrolatum gauze, as is customary in my method, and the entire limb placed in a plaster-of-paris closed cast. The pins in the calcaneum and in the upper fragment of the tibia were included in the cast to give fixed traction in correct length and position. The patient had no shock following the operation and was, indeed, in better condition and much more comfortable than at any time since his injury.

In this case there was a deviation from my usual routine which, for particular reasons, I desire to explain. On the fifth day following the operation Dr. Allen B. Kanavel of Chicago was in Lincoln and was seeing a number of my compound fracture and osteomyelitis cases. I was anxious to have him see the exact condition of this wound and graft at this particular stage. The patient was comfortable and free from fever, and it was felt that I might vary from my usual custom and expose the wound to afford Dr. Kanavel an opportunity to see the condition of the wound and the limb. An opening was made in the cast and the dressings lifted sufficiently for an inspection. The petrolatum pad and the other dressings were lifted up and then let down again without being changed, so that the original dressing remained in place until November 21, at which time the first formal dressing was done.

At the time of Dr. Kanavel's inspection the wound was observed to be clean, there was no evidence of inflammation or pus, there was a large healthy looking clot, and the leg was free from swelling or deformity.

At the time of dressing, November 21, there was a moderate amount of discharge, there was no odor, the wound and the graft were clean and appeared to be healing satisfactorily. The leg was somewhat loose in the cast, so that the packing about the middle portion of the leg and the fracture region was renewed and made tighter. The portion of the cast that was holding the pins in the heel and in the upper portions of the tibia was not disturbed, and there was consequently no loss of length or position.

The patient continued to progress satisfactorily after this time, and seven weeks after the original operation the entire cast was taken off, the traction and fixation pins were taken out, and a new cast was applied with a very thin layer of padding over the entire limb. There were no local or general inflammatory complications of any importance at any time. Even at this time there was sufficient bone repair so that the leg would support itself although the callus was still quite soft. A few days later he was permitted to go home for the Christmas holidays and since that time has spent only a few days in the hospital for two changes of cast and dressings. The accompanying roentgenograms were taken April 30. There has been some delay in the union of the lower end of the graft, which was intramedullary instead of cortical as at the upper end. This suggests that fixation into the cortex may be better in these cases. It is apparent that he is making an excellent recovery with a greatly shortened period of hospital care and disability.

CONCLUSION

This case demonstrates that such a program of treatment is feasible. A bone transplant may be put into an infected area and by suitable fixation immobilization and protection of the wound against mixed infection the patient may be carried through to healing of the wound and repair of the bone defect at the same time. This appears to demonstrate that the infectious complications to which one has been accustomed in most of these cases and which delay not only the healing of the soft part wound but also the repair of the fracture are due to mixed secondary infection incurred

by the patient in the course of secondary so-called antiseptic dressings. If the patient can be protected in the manner that I have suggested and approximately primary results can be obtained, a great saving in hospital expense, length of disability, and ultimate deformity may be made.

1307 N Street

ABSTRACT OF DISCUSSION

DR. EARL D. McBRIDE, Oklahoma City. To comprehend the success of Dr. Orr's method of treating infected wounds it is necessary to understand the role of the leukocyte and the granulating cell activity. The action is of two types: (1) the intracellular absorption and (2) the enzyme digestion through the splitting up of proteins, fats and carbohydrates into the albuminoses, peptones, and so on. In compound fractures the liberating of enzymes destroys infection. It may be called bacteriophage, as described by d'Herelle, or it may be considered

Fig. 2—Appearance of the fracture region in April, 1933. This was six months after injury and immediate bone graft operation. The upper end of the graft which was tied into the groove from which the graft was taken is soundly united by bony union. The lower end of the graft which was driven into the medulla of the lower fragment is uniting more slowly.

the cleavage of toxic products described by Jacoby, Wells and others. The popular war method of treating osteomyelitis and compound fracture was that of using the Carrel-Dakin technique of chemically removing the products of suppuration. This method does not fulfil the necessary biologic principles. To produce phagocytosis and enzyme digestion in a granulating wound, three local factors are essential: (1) constant and adequate drainage; (2) firm splinting of granulation; and (3) a constant degree of temperature. This is necessary and is greatly lacking in other forms of treatment. The application of a plaster cast maintains a constant temperature and favors production of cell products. It does not make any difference whether one is treating infected wounds or the osteomyelitis type or doing a bone graft operation in a compound fracture, the same processes take place.

DR. H. WINNETT ORR, Lincoln, Neb. Those who have employed the Orr method in osteomyelitis and in compound fractures realize that all they have been endeavoring to do is

to furnish conditions under which the patient has the best chance to recover. That is the main object of this method. The series of experiments with regard to bone repair that have been reported may contribute considerably to knowledge of the details of repair. The method devised by me in 1921-1922 and first reported in 1923 consists not only of infrequent dressings with aseptic (not antiseptic) petrolatum gauze pads but of an adequate drainage operation when required, immobilization to prevent trauma during and following operation and prolonged protection of the patient against irritative motion, muscle spasm, secondary wound infection and deformity. It is the combination of these factors and not the use of any one or two that constitutes the Orr method.

ARTERIOLES OF THE RETINA IN TOXEMIA OF PREGNANCY

HENRY P. WAGNER, M.D.

ROCHESTER, MINN.

That retinitis occurs with some forms of toxemia of pregnancy is recognized. However the clinical significance of such retinitis is not well understood. There have been two main sources of difficulty in the interpretation of its relation to the underlying disease: (1) the varying terminology used by ophthalmologists to describe and designate the retinitis, and (2) the varying classifications of toxemia by obstetricians and clinicians. Although greater uniformity is being gradually attained in both of these phases, it is still hard to avoid the rather meaningless term albuminuric retinitis and it is still difficult immediately to classify individual cases of toxemia with absolute accuracy. It does not seem feasible at the present time to attempt to prove that retinal lesions occur exclusively in any one type of toxemia of pregnancy. It does seem, however, that the changes seen in the retinas of patients with toxemia are sufficiently constant to furnish if properly interpreted from the clinical standpoint valuable aid in the estimation of the patient's immediate and future course. I believe that clinical interpretation should be based primarily on the arterioles of the retina and only secondarily on the retinitis.

Fig. 1—Residual phase of retinitis of toxemia of pregnancy. Marked spastic and sclerotic narrowing of the arterioles is shown. Diffuse edema of the retina is still present.

as the completely developed picture of the retinitis. Cheney,² in 1924, stated that if a patient with toxemia has retinitis, the chances are four to one that she also has nephritis. He agreed with Schiotz,³ however, that retinitis does occur in cases of acute toxemia of pregnancy without evidence of preexisting nephritis and

that a few of these patients do not show evidence of residual nephritis after the subsidence of the toxemia. Neither Miller nor Cheney emphasized the significance of the vessels of the retina in their cases of retinitis although they both noted evidences of arterial constriction, and Cheney felt that the demonstration of actual arteriosclerosis in association with the retinitis justified the diagnosis of chronic nephritis.

Mylus,⁴ in 1928, demonstrated satisfactorily that in toxemia of pregnancy associated with a rise of blood

Fig. 2—Arterioles in a portion of the pectoralis major muscle removed at biopsy (same case as fig. 1). There are definite thickening of the walls of the arterioles, reduction in the size of the lumens, proliferation of the intima and hypertrophy of the media, reduced from a magnification of 415 diameters.

pressure the primary and most commonly observed lesions of the fundus were spasms and tonic constrictions of the retinal arteries. These occurred both in cases of acute toxemia and in cases in which chronic nephritis had existed previously. Mylius stated his belief that retinitis developed as the result of passive congestion in the venous capillary loops secondary to the tonic arterial constrictions.

If the retinas of pregnant women whose blood pressures are rising are examined systematically and frequently before the onset of disturbances of vision, the existence of the changes described by Mylius can not be doubted. His interpretation of the nature of these changes and of the mode of onset of the retinitis may be open to question, but his comprehensive reports of cases and photographs make further detailed description of the ophthalmoscopic appearance unnecessary. Suffice it to say that usually the first visible sign is a narrowing of the arterioles of the retina which may affect any or all of the branches of the central artery. This narrowing is often accompanied or followed by irregular constrictions of the lumen of the arterioles, usually first or most marked in the smaller nasal branches, which may vary in degree and situation from day to day. Later, as the narrowing and constrictions become more fixed, individual cotton-wool patches and hemorrhagic areas may appear in the retina, and, finally diffuse retinitis of the albuminuric type may develop.

If the patients who manifest arteriolar changes are receiving proper medical care hemorrhages and cotton

wool patches will seldom occur, and, perhaps, diffuse retinitis should never be allowed to develop before delivery. Except in the presence of diffuse retinitis, these patients have little if any disturbance of vision. With the exception of the retinal detachments from subretinal exudation, all the so-called types of retinitis are only phases and extensions of primary lesions of the arterioles.

The variability of the narrowings and constrictions and their usual tendency to rapid disappearance after the termination of the toxemia certainly suggest that they are the visible signs of an angiospastic rather than an angiosclerotic lesion. The apparent permanence of some of the vascular changes indicates, however, that at some stage of the spastic process actual organic changes occur. Ophthalmoscopically, it is often difficult to determine just when the organic stage sets in. It has seemed probable that constrictions and irregularities which are still present two weeks after delivery are sclerotic and no longer simply spastic. Recent histologic studies of the arterioles in sections of peripheral muscle tissue obtained at biopsy suggest that organic changes in the intima occur early in the vasospastic phase of the toxemia and may be present from the onset.

Unless Volhard's⁵ or Mylius' view of the pathogenesis of the retinitis in these cases is accepted, it would seem rational to assume that organic vascular changes are present when retinitis develops. The more accepted idea that organic arteriolar lesions form the basis of the vascular types of retinitis is summarized and supported by Friedenwald.⁶ "The vessels primarily affected are the terminal or precapillary arterioles, and the retinal lesions are in essence minute foci of necrosis oedema, and hemorrhage dependent on vascular occlusion." He stated that this basic vascular occlusion is organic and not spastic, and that it is due to "an acute necrosis of the vessel wall with total disappearance of all cellular outlines and the replacement of the tissues by an amorphous protein coagulum." From the purely clinical standpoint, however, although it is evident that permanent arteriosclerosis remains as a residue in most cases of diffuse retinitis of toxemia of pregnancy, it is also true that, in some cases especially when the retinitis is localized rather than diffuse, any permanent residual arteriosclerosis is so slight as to be clinically negligible. It seems possible therefore that mild retinitis can develop in the vasospastic phase of the toxemia before organic changes occur of sufficient degree to be irreparable. In most cases of severe diffuse retinitis, however, definite organic vascular changes are the inevitable residue.

It is obvious then, that with few exceptions the primary lesion in the retinas of patients with hypertensive toxemia of pregnancy is in the arterioles. Hemorrhagic edematous or exudative areas develop secondary to these arteriolar changes as a result of interference with the nutrition of the retina. Clinically, at least all the ophthalmoscopically visible branches of the central artery of the retina are best considered as arterioles. That is it has been shown in the usual types of cardiovascular renal disease that disease of the arterial branches of the retina is a part of a diffuse disease of the arteriolar rather than of the arterial

system and that, in the main, the type and severity of the involvement of the systemic arterioles closely approximate the type and severity of the lesions visible in the retinal arterioles. This fact is now rather generally accepted in the interpretation of primary or essential hypertension. In glomerulonephritis, it seems probable, conservatively, that although the factors of generalized edema and anemia may play a part in the causation of the associated retinitis, lesions of the retinal arterioles and a vascular type of retinitis do not develop until diffuse arteriolar spasm or sclerosis occurs as a secondary or complicating factor to the primary nephritis. Because of this, it is not always possible for the ophthalmoscopist to distinguish between the retinitis of primary hypertension and that of primary glomerulonephritis unless he is assisted by the recognition of the additional factors of edema and anemia in the retinal picture. He can always, however, unless the vessels are too greatly masked by edema, give a valuable estimate of the degree of associated arteriolar spasm and sclerosis. It seems justifiable to assume that in the toxemia of pregnancy, likewise, the presence of lesions in the retinal arterioles is an indication of involvement of the systemic and renal arterioles of similar type and severity, and that the development of retinitis indicates the approaching onset of organic injury to the retinal, systemic and renal arterioles which will be, in part at least, irreparable. This is of particular significance with reference to the future well being of the mother, since it is probable that hypertension will persist in the presence of diffuse generalized arteriosclerosis. Although the occurrence of retinitis does not justify the diagnosis of glomerulonephritis, it obviously indicates the probability of serious involvement of the renal arterioles along with the systemic arterioles and the probable persistence after pregnancy of a low reserve, or an arteriosclerotic kidney. Interpreted in this way, it seems clear that in toxemia of pregnancy every effort should be made to terminate the toxemia, even by the interruption of pregnancy, before the development of diffuse retinitis. Thus, ophthalmoscopic examinations should be made at frequent intervals without reference to the absence of disturbances of vision, especially if the patient has a rapidly rising blood pressure and angiospastic changes are present. As long as the lesions in the arterioles are definitely spastic, if the condition of the patient is otherwise satisfactory, it is safe to temporize. The appearance of individual cotton-wool patches and hemorrhagic areas gives warning of the near approach of permanent organic changes in the arterioles. If these lesions increase in number from day to day, pregnancy must as a rule be terminated if the future integrity of the systemic and renal arterioles, as well as of the retinal arterioles, is to be preserved. It is true that permanent organic lesions, although usually of less severe degree, develop at times in the arterioles as a sequel to the spastic changes in cases in which retinitis has not developed. At present, it does not seem possible to determine accurately the transition point, but the ophthalmologist can sometimes indicate his belief that organic changes are at least impending even in the absence of retinitis.

As yet no exact means have been devised for determining the presence and degree of generalized arteriosclerosis. Histologic study of the arterioles in a portion of peripheral muscle obtained by biopsy furnishes valuable information but such information is

⁵ Volhard. Die Pathogenese der Retinitis albuminurica. *Zentralbl. f. d. ges. Med.* 21: 1-9 (March) 1920.
⁶ Friedenwald, I. S. The Pathogenesis of Albuminuric Retinitis. 15-27. Anniversary Volume. New York, International Press, 1952. vol. 1, p. 433.

not available in all cases. It is rather generally assumed that elevation of the blood pressure, especially of the diastolic pressure, is a sign of generalized narrowing or sclerosis of the arterioles throughout the body, and that a persistently high diastolic pressure indicates actual arteriolosclerosis. Even in cases of glomerulonephritis, the associated hypertension is probably best explained on the basis of generalized narrowing or sclerosis of the systemic arterioles. A definite relationship can be demonstrated between the changes in the retinal arterioles observed during hypertensive toxemia of pregnancy and the tendency to persistence of the hypertension after the termination of pregnancy.

From the standpoint of hypertension only, two main types of pregnancy must be considered: those in which hypertension has been known to exist prior to the onset of pregnancy, and those in which the blood pressure rises acutely from levels which were normal before pregnancy and during the early months. In a certain percentage of the first type, although the blood pressure may rise slightly during the latter months of pregnancy, toxic symptoms do not develop, and any changes in the fundus are of the organic arteriolar type. After the termination of pregnancy, the blood pressure returns rapidly to its previous level. In other cases of this type, however, the blood pressure rises coincidently with the appearance of symptoms of toxemia, and spastic arteriolar changes and retinitis can appear primarily or be superimposed on previous organic arteriolar lesions. The course of these lesions is essentially the same as those appearing in cases of the second type in which blood pressure has been normal previously. The lesions can disappear without residue or they can be followed by organic arteriolar changes, or by an increase of the organic changes already present. In some cases there is a definite tendency to recurrence of toxemia in succeeding pregnancies. The blood pressure may or may not be elevated between pregnancies.

The data in tables 1 and 2 indicate that the probability of the persistence of hypertension after the termination of pregnancy is definitely related to the development of organic changes in the retinal arterioles. After delivery the blood pressure returned rapidly to normal in all cases in which the arterioles of the retina had been normal throughout the toxemia. Of twenty-eight cases in which the arterioles returned to normal

after the subsidence of the spastic phase, persistent hypertension followed pregnancy in only two. In sixteen cases in which residual sclerosis of the retinal arterioles was present after the subsidence of the spastic phase, persistent hypertension was present in fifteen. Sclerosis of the arterioles is an almost constant residue of diffuse retinitis; it failed to appear in only one of

eight cases. It is not so constant a residue of localized retinitis; it failed to appear in four of eight cases. Spastic arteriolar lesions occurred in 60 per cent of cases of toxemia in which hypertension had been present previous to pregnancy, in 73 per cent of acute toxemia without convulsions, in 70 per cent of acute toxemia with convulsions, and in 90 per cent of recurrent toxemia. By contrast, it may be noted that retinitis occurred in 20 per cent of cases of toxemia with previous hypertension, in 30 per cent of acute toxemia without convulsions, in 40 per cent of acute toxemia with convulsions and in only 10 per cent of recurrent toxemia. This relative infrequency of retinitis in cases of recurrent toxemia is recognized, but has not been definitely explained. Hypertension remained permanent in five of eight cases of localized retinitis and in eight cases in which diffuse retinitis was present during pregnancy. The serious nature of the residual injury to the vascular system of a patient with toxemia of pregnancy and diffuse retinitis is well illustrated by the following case.

REPORT OF CASE

A woman aged 41, was admitted to the hospital in the seventh month of her eighth pregnancy. The preceding seven pregnancies had been normal so far as she knew. For about ten days before admission she had severe abdominal pains and marked blurring of vision. The blood pressure had not been taken but on admission it was 250 systolic and 160 diastolic in millimeters of mercury. The urine contained albumin graded 3 and many casts. The concentration of urea was 40 mg for each 100 cc of blood. Extensive diffuse retinitis of the angiospastic (albuminuric) type was present in each eye. The patient was delivered five days later. The blood pressure did not fall rapidly after delivery, and was 242 systolic and 142 diastolic at the end of two months. After four months the systolic blood pressure was 172 and the diastolic 120. Ophthalmoscopic examination at this time revealed sclerosis graded 3 of the retinal arterioles with residue of the acute retinitis. Sixteen months after the termination of pregnancy the systolic blood pressure was 180 and the diastolic 130 and ophthalmoscopic examination revealed sclerosis graded 3 of the retinal arterioles with only the scars of previous retinitis and no signs of activity. The appearance of the retina did not change much after this although a few small hemor-

rhagic areas appeared in the retina from time to time. Three years later, the patient returned to the clinic with left hemiplegia and left homonymous hemianopia, apparently the result of cerebral hemorrhage or thrombosis. The systolic blood pressure at this time was 170 and the diastolic 110. Urinalysis gave negative results except for the presence of albumin graded 1. The concentration of urea was 10 mg for each 100 cc of blood. At the end of three years the systolic blood pressure was 186 and the diastolic 130, and one year later the patient died as the result of a second cerebral vascular accident. Necropsy revealed hypertrophy of the heart (548 Gm compared with the normal of 300 Gm for a person of corresponding height and weight), multiple old and fresh cerebral hemorrhages, and generalized arteriosclerosis graded 2 with arteriosclerotic changes graded 1 in the kidney. The glomeruli were well preserved.

In this case, then, following acute toxemia of pregnancy which did not progress to the stage of eclamptic convulsions but which was complicated by the presence of diffuse angiospastic retinitis, severe hypertensive dis-

of origin of the edema, which is largely subretinal. It is questionable whether the edema is to be regarded as part of the general edema present in such cases, or whether it is the result of spastic changes in the choroidal arterioles. As Friedenwald pointed out, changes in the choroidal arterial circulation are not so closely linked to those in the systemic arteries and arterioles as are lesions in the retinal arterioles. This probably explains the absence of persistent hypertension in these cases of retinal detachment.

In two cases in the clinic, extensive bilateral detachments of the retina occurred a few days before delivery, associated in each case with a moderate rise of blood pressure and moderate generalized edema. One of the patients had eclamptic convulsions. Both patients had normal blood pressures within a month after delivery, the pressure of one patient was 114 systolic and 72 diastolic six months afterward. The other patient has had two subsequent normal pregnancies. Her blood

8	Acute previous hypertension	Arteriolar spasms diffuse retinitis	200	180	Retinitis still active	200	130	Sclerosis graded 3 residue of retinitis	178	110	Systolic 142 diastolic 100 1 year before pregnancy 6 years later systolic 230 diastolic 140 right hemiplegia sclerosis graded 3 with recurrent retinitis

case persisted and progressed in eight years to death as a result of the last of a series of cerebral hemorrhages. Even if the primary disease during pregnancy was glomerulonephritis, the end-result was diffuse arteriolar disease and it seems more probable that the primary lesion was also in the arterioles. Not all cases of this type run such a severe and steadily progressive course. However, it seems probable that the residual lesion in any case of toxemia of pregnancy complicated by retinitis will be at least partially arteriosclerotic. This statement does not hold true for the primary detachments of the retina occurring in association with the toxemia of pregnancy, since in these cases the underlying lesion probably is not in the retina or the retinal arterioles. In cases of eclampsia or preeclamptic toxemia in which detachment of the retina occurs without primary or preceding retinitis, the probability of residual permanent vascular disease seems to be distinctly less than in cases of diffuse retinitis of the angiospastic type. As suggested by Crowther and Hamilton¹ the choriocapillaris seems to be the source

pressure seven years after the toxemia and detachment was 120 systolic and 80 diastolic. A third patient had a similar type of subretinal edema without lesions in the retina or retinal arterioles. Her blood pressure returned to normal within three weeks. She had two normal pregnancies subsequently but in the fourth pregnancy hypertension with spastic changes in the retinal arterioles and mild retinitis developed. Two months after the termination of this pregnancy, the retinal arterioles were sclerotic, graded 1, and the blood pressure was 130 systolic and 95 diastolic.

The histories of cases summarized in table 3 illustrate the future course in cases in which varying types of retinal lesions were present in association with hypertension during pregnancy.

CONCLUSIONS

1 Spastic lesions of the arterioles are the most frequent and usually the primary signs of retinal involvement in toxemia of pregnancy.

2 The spastic lesions occur both in acute toxemia and in toxemia superimposed on previous vascular or renal disease.

¹ Crowther W. L. and Hamilton I. R. Eclampsia with Amaurosis Due to Detachment of the Retina. *M. J. Australia* 1:1-18 (Aug. 6) 1932.

3 Spastic lesions occur in about 70 per cent of cases of toxemia

4 In about 60 per cent of cases, the spastic lesions disappear with the termination of pregnancy and the blood pressure returns to normal or to its previous level

5 In about 40 per cent of cases organic lesions develop in the arterioles, often in association with retinitis. In such cases, elevation of blood pressure usually persists

6 Diffuse retinitis of the albuminuric type is to be regarded as evidence of severe generalized arteriosclerosis rather than of primary nephritis

7 Primary detachment of the retina occurring in the course of acute toxemia does not have the same serious clinical significance as diffuse retinitis

ABSTRACT OF DISCUSSION

DR ROBERT J. MASTERS, Indianapolis. Not infrequently the eyeground picture is the deciding factor as to the immediate and subsequent management of a patient suffering with pregnancy toxemia. I agree with the author that the ophthalmoscopic observations of the greatest clinical importance are based on changes in the retinal arterioles. The occurrence of various degrees of pregnancy retinitis depends on the degree and duration of the primary retinal arteriolar changes. The appearance of the picture called pregnancy retinitis seems to follow no rule as the most severely toxic patients may have no retinal exudates or hemorrhages. Constriction of the retinal arterioles is constantly seen, however, in all patients whose blood pressure is elevated to 150 or more systolic and 100 or more diastolic. For the purpose of proving this arterial constriction by measurement, I have employed an ophthalmoscope that projects a linear graticule on the eyeground. The use of this instrument was suggested to me by Dr Wagener. Changes in the retinal arteries probably indicate, to a reasonable extent, changes in the arterioles of the rest of the body. Constriction of the retinal arteries therefore suggests a generalized arteriolar constriction sufficient to elevate the blood pressure. This arteriolar constriction is probably the result of irritation produced by a toxin circulating in the blood stream. If the toxic irritant is allowed to continue its action too long before pregnancy is terminated, its effect will advance from the stage of irritation with arteriolar constriction to a stage of destruction with sclerotic changes in the vessels, permanent vascular hypertension and chronic nephritis of various degrees of severity. This permanent damage I have seen, as noted by the author, in patients who have shown only a retinal arterial constriction, without retinitis during their acute toxemia. The possibility of arteriosclerosis, persistent vascular hypertension and chronic nephritis in young women requires more thought than does risk to their future vision. All the toxic patients whom I have studied at the maternity hospital of Indiana University have come through with useful vision, whereas almost three fourths have exhibited evidences of chronic nephritis following or complicated by toxemia and almost one third had sclerotic changes in the retinal arteries.

DR ARTHUR J. BEDELL, Albany, N. Y. When the retinal changes in pregnancy become fixed they are easily demonstrable, and when hypertension persists after delivery the systemic damage is irreparable. This is illustrated by the case of Mrs. S., aged 42, who was examined eight years after a cesarean section in the eighth month. She was blind four or five days before the operation. Her blood pressure has never returned to normal and the fundus picture clearly illustrates the marked changes in the retinal arteries and veins. In cases of well established hypertension one finds not only the wide spread arterial changes but also white, powder-like exudates as shown in S. P., a 38 year old woman who had toxemia and severe retinitis during the terminal stages of a pregnancy. Her tension remains elevated and her vision reduced. That any unrecognized or improperly treated toxemia of pregnancy is a serious condition is illustrated by the history of H., aged 30 who entered a hospital five weeks before the date of expected

delivery. Three weeks before that time she had had transitory attacks of almost complete blindness. She was allowed to continue to term, although her systolic pressure was 220 and her diastolic pressure high. For four and one half weeks she could not even recognize her attendants. The photographs taken ten months after delivery of her dead child show the intense degeneration of the retina, the markedly irregular artery lumen, and the atrophy of the disk. The vision was 10/200. Her pressure continues high, and not only has she lost much sight but her general vascular system has undergone a serious and permanent change. I trust that these signs will receive early recognition. For many years it has been known that blood vessel spasms were visible in the retina. They have been so elusive, however, that few photographs have portrayed them. As I understand Dr. Wagener, his plea is that ophthalmologists, when called on to render an opinion on the conditions found in the fundus of a pregnant woman suffering from toxemia, should urge and insist on the removal of the cause of the toxemia during the stage of arteriolar spasm, instead of waiting until the lesion becomes fixed. These photographs uphold his contention and should be an object lesson to all who are in doubt as to the imperative necessity for immediate delivery.

DR HENRY P. WAGENER, Rochester, Minn. I wish to thank Dr. Masters, and particularly to thank Dr. Bedell for the photographs which he has shown supplementing and far surpassing those I have shown and illustrating a point that I wished to demonstrate, namely, that definite organic changes follow spastic lesions in the arterioles. I might also reemphasize what Dr. Bedell said in closing, that when the ophthalmologist is called to see a case of toxemia of pregnancy he should focus his attention not only on the presence or absence of retinitis but particularly on the condition of the retinal vessels and that he should if possible advise delivery before the changes in the arterioles become organic. The obstetrician should realize that, if he will ask for ophthalmologic consultation in the early stages of the toxemia when the blood pressure begins to rise, there is a chance to discover these changes before the patient complains of blurring of vision.

LIMITS OF THE ANTI-INFECTIONAL VALUE OF PROVITAMIN A (CAROTENE)

S. W. CLAUSEN, M.D.

WITH TECHNICAL ASSISTANCE OF AUGUSTA B.
McCOORD, B.A.
ROCHESTER, N. Y.

Investigations have indicated with a high degree of certainty that carotene may be converted in the liver to vitamin A. This fact makes possible a chemical approach to the problem of the anti-infective action of vitamin A. In the studies about to be reported, the carotinoid pigments of the blood were determined by the method of Connor.¹ The pigments determined by this method include carotene and xanthophyll. In order better to understand the results obtained the vitamin A content of the blood and of the liver in children coming to autopsy and in experimental animals was determined by a modification of the antimony trichloride test of Carr and Price.² The uncertainty of this method is recognized, but the results appear so consistent and the variations in different conditions are so large, that the method seems sufficient for our purpose. An arbitrary unit is employed. It is equal to about 0.01 Sherman unit.

The so-called anti-infective value of carotene may be studied in two ways (1) By observing the effects of administering this substance over a prolonged period in a group of children, and comparing the results with those in a control group. One objection to this method is the fact that many older children habitually choose a diet rich in carotene. If this habit were not known in individual cases, it would introduce a complicating factor. (2) By observing the level of plasma carotinoids in a large group of persons, and correlating these levels with the known susceptibility of the children to repeated respiratory infection. The latter method was selected. Before presenting the results of this study, it is necessary to discuss various factors which affect the level of plasma carotinoids.

When carrot puree, $\frac{1}{2}$ ounce, twice a day, is administered to healthy infants, a rise of the level of carotinoid pigments of the blood usually follows. The carotene

Chart 1—Rise of the level of plasma carotinoids caused by adding carrot puree to an infant's diet at the points indicated by T. C. discontinuance of the puree at points indicated by I. C. The figure shows good absorption in the case of J. R. and poor absorption in the case of R. W.

content of the plasma has been expressed in units of thousandths of a milligram per hundred cubic centimeters, i. e., 1 unit is equivalent to 1 gamma per cent. In J. R., aged 2 months (chart 1), the level of plasma carotinoids steadily rose from 10 to 76 units in nine

Chart 2—Poor absorption of carotinoids during fever (F) and diarrhea (D). Absence of protection against respiratory infection (myringotomy indicated by M). This child later on required mastoid operation.

days. The rise continued for two days after carrot puree had been discontinued. R. W., 4 months old, received the same quantity of carrots but showed a rise in the level of plasma carotinoids of only 11 units. Children with diarrhea, fever, or both, show little rise. F. H., 10 months old (chart 2), received carrot puree

for two months, during a period of fever and diarrhea, the level of plasma carotinoids remained low; during and after recovery, a rapid rise ensued, then fever recurred, with a fall in the level. Otitis media and mastoiditis finally developed.

Chart 3—Curves showing the level of carotinoids due to the absorption of carotene from a solution of carotene in oil given by mouth during the course of scarlet fever. The absorption is better in the absence of complications.

Carotene in oil (1:2,000) was administered to a number of patients with scarlet fever throughout the illness. The average level of plasma carotinoids is shown in chart 3. Here again, the slow rise during fever is obvious. It is therefore apparent that prepara-

Chart 4—A comparison of the rates of absorption of carotene and of vitamin A after the ingestion of 10 cc of carotene in oil 1:2,000 and 2 cc of halibut liver oil showing more rapid absorption of vitamin A.

tions of carotene may be poorly absorbed under certain conditions.

Vitamin A is much more readily absorbed from the intestinal tract of children than is carotene, after a dose of 2 cc of halibut liver oil, the level may rise from 15 to 270 arbitrary units at the end of four hours (chart 4). It is therefore obvious that, under certain conditions, halibut liver (or cod liver) oil may be superior to carotene. However, we have observed that in chronic diarrheas and in celiac disease even during

2a. The vitamin A potency is about 7,000 units per gram. Halibut liver oil plain now being placed on the market contains 37,500 vitamin A units per gram.

periods free of diarrhea the absorption of vitamin A is slight

It was found that infants who have not received vegetables, egg yolk or top milk mixtures never have a high level of plasma carotinoids. After the age of 2 years, however, the average level of plasma carotinoids of healthy children is nearly constant at about 80 units. There is a slight rise in summer. Children with infections, however, show a marked lowering, which in general corresponds with the severity of the infection. In chart 5, the rectangles indicate the range of plasma

Chart 5—Plasma carotinoids in various infections. The rectangles represent the range covered by the median half of the cases studied. The numbers to the left represent the total number of cases. Normal children, acute respiratory infections, chronic otitis media, pyuria, acute otitis media, sinusitis, scarlet fever, acute tonsillitis, acute appendicitis, abscess (various locations), active pulmonary tuberculosis, pneumonia, septicemia.

carotinoids within which fell the median half of cases of various conditions, the figures to the left of the rectangles show the total number of cases of each condition. From what has already been said, it will be evident that a low level of carotinoids cannot be considered as preceding, or predisposing, to the infections, but rather, as a consequence of the infection. This lowering may be due to any of three causes: (1) more rapid utilization in fever, (2) slower absorption and (3) poor appetite. The rate at which the level of plasma carotinoids falls when healthy children receive a carotene-free diet is only slightly slower than the rate of fall during the first week of scarlet fever, in patients on the same diet (chart 6). This would indicate that poor appetite and poor absorption during fever account for the observed lowering of the level of carotinoids. If, therefore, we wish to study the relationship between plasma carotinoids and resistance to infection, we must consider children healthy when examined. It is possible to show that the level of carotinoids in a child is fairly constant, lowering occurs during an infection, a return to the individual level takes place within about ten days after fever disappears. We have studied 1,322 children over the age of 2 years. We have grouped together those children whose carotinoid level fall within ranges of 20 units, in each group, the percentage of children subject to repeated respiratory infection has been recorded. This information has been taken from the clinical record. As may be seen from table 1, the apparent susceptibility to repeated respiratory infection falls with a rise in the level of carotinoids, until a value of about 120 units is reached. Thereafter, the susceptibility rises. We have also recorded in this table the results in children with mild and with severe infections. As already stated, a marked fall is noted during infec-

tion. Nevertheless, it is apparent that there exists an intermediate range of values for plasma carotinoids, within which the susceptibility to repeated respiratory infection is lower than in the higher or lower ranges.

If it be assumed for argument that a low level of plasma carotinoids predispose to repeated respiratory infection, the importance of this factor is not great. Not more than from 5 to 10 per cent of this susceptibility in the children studied can be attributed to a low

Chart 6—Rate of fall of the level of plasma carotinoids in scarlet fever and in children consuming diet low in carotene.

level of carotinoids.³ The increased susceptibility among children with a high level of carotinoids suggests a possible injurious action of carotene, at least, it would indicate caution in the use of concentrated preparations in certain persons. We have gained the

³ Clausen, S. W. The Exploitation of the Vitamins. New York State M. J. to be published.

impression that children with xanthosis cutis⁴ are rather susceptible to respiratory infection

Our own data on the administration of carotene are limited to a study of seventy-five cases of scarlet fever. We have found that the administration of carotene in oil (from 5 to 10 cc of 1:2,000 in Mazola oil [corn oil], once a day) to half of these children throughout their illness and convalescence had no demonstrable beneficial effect on fever or complications.⁵

We believe that the absence of benefit from the use of carotene and the absence of any striking correlation

Chart 7—Lack of correlation between the level of vitamin A in blood and in liver

between the level of plasma carotinoids and the susceptibility to repeated infections may be explained in one of two ways. The supply of vitamin A in the liver in our cases may have been entirely adequate for protection, or, vitamin A may be of little importance as an anti-infective agent in the age-group considered. Some evidence on these points may be gained by analyses of blood and of liver for vitamin A. The normal level of vitamin A in the blood of rats—from 15 to 25 units—is independent of the quantity stored in the liver (chart 7).⁵ Moreover, the level in the

blood is subject to wide variations, as may be shown by feeding experiments. Consequently, the vitamin A level in the blood is no criterion of the quantity stored. For any proper understanding of our problem, we must ascertain the amount in the liver. Miss A. B. McCoord and Dr. E. L. Clausen have found that in the rat the liver may store quantities greatly in excess of those necessary to prevent symptoms of deficiency; in animals suffering from symptoms of deficiency, the content was found to vary from 0 to 40 arbitrary units per hundred grams; animals on the Sherman B diet from the age of 4 to the age of 8 weeks had no signs of deficiency of vitamin A, although the A of the liver was only 300 units; at 17 weeks on the same diet, the content was 2,800 units. One drop of halibut liver oil per week for thirteen weeks caused a rise to 31,400 units. The incidence of spontaneous otitis media was precisely the same in these animals as in the control group. Analyses of livers of rats which had received, twenty-four hours beforehand, 1 or 2 drops of halibut liver oil make it possible to calculate that 13 drops should have raised the content in the liver to 36,400 units. Comparatively little, therefore, has been lost in the period of thirteen weeks. The animals with spontaneous infections did not have less vitamin in their livers.

The vitamin A content of livers of seventy children coming to autopsy was also determined. A summary of the results in table 2 indicates that older children who died of severe infections have less vitamin A in their livers than those who died of other causes. In several who died of severe infection, relatively high values were found. Very low values were observed in congenital atresia of the bile ducts (35 units), syphilis with lardaceous liver (31 units), and pneumonia fatal in the first two days of life (25, 160 and 95 units); low values were also observed in two older children, badly fed, who died of dysentery (580 and 835 units). It is possible that the low values found after fatal infections may have been the result of the infection. We have tried to get some idea about the rate of fall of vitamin A in the liver by comparing the average values found in livers of children who succumbed to severe infections at different times, in spite of the variability among children, the average does not fall much until the fifteenth to twentieth day. It is therefore possible that low values of vitamin A in the liver of older children may sometimes exist before the onset of severe infections, and lower resistance. Much more must be known about the normal vitamin A content of the liver in childhood. It should be pointed out that few if any of our patients had as little vitamin A as rats which seem adequately protected—300 units.

We have had the opportunity of analyzing livers of rats in an experiment conducted by Dr. Oliver R.

TABLE 2—Vitamin A Content of Liver Seventy Cases

Diagnosis	Number	Vitamin A Units per 100 Gm		
		Maximum	Minimum	Average (or Single Determination)
Children over 6 months of age				
No infection—sudden death				
Pyloric stenosis	1			73 000

McCoy on the effect of deficiency of vitamin A on susceptibility to infection with trichinosis. He finds that the rat, weaned at 4 weeks, then placed on a diet deficient in vitamin A for eight weeks, is very susceptible to this infection (vitamin A of liver, from 0 to 40 units); if the rat has received a diet of commercial dog-chow for eight weeks after weaning, resistance is good (A of liver from 220 to 315 units). If the rat is placed on the deficient diet at 8 or even 10 weeks, and infected at 12 weeks or 5½ months (respectively), the resistance is good although at death the liver is free of vitamin A. This work shows that the vitamin A stores

⁴ Caremia is a disease. Carotene is usually present in the blood of rats over 2 years of age.

⁵ McCoord, A. B., and Clausen, E. L. Personal communication.

in the liver of older rats may readily be depleted, without causing marked loss of resistance. However, the resistance of the rat may be improved by the use of cod liver oil, which in the experiments cited raised the vitamin A of the liver from about 300 units to a level of from 8,000 to 15,000 units. Much more extensive work must be done with other types of infection. It seems likely, however, that, if the rat is deprived of vitamin A during the period of rapid growth, its tissues are so altered that resistance is lowered. It is suggested that vitamin A may be especially important during the period of human infancy.

CONCLUSIONS

The foregoing discussion seems to justify these conclusions:

1 Children over the age of 2 years are likely to receive a diet containing a sufficient amount of vitamin A. Results of analysis of the plasma for carotene suggest that not more than 5 or 10 per cent of recurring respiratory infections can be attributed to a low intake of carotene.

2 The livers of children at autopsy usually contain considerable amounts of vitamin A, whether or not these quantities are sufficient to protect against infection can be decided only by much more extensive study.

3 During the period of rapid growth in experimental animals, adequate amounts of vitamin A are needed. If vitamin A is withheld during rapid growth, the tissues are so altered that resistance to infection is low. If vitamin A is present during this period, the organism may subsequently be depleted of its stores of vitamin A without developing a marked loss of resistance to certain infections.

4 When rapid storage of vitamin A is desired, halibut liver oil, or cod liver oil, would seem more suitable than preparations of carotene, because of the more rapid absorption of vitamin A than of carotene. Carotene is poorly absorbed in the presence of fever or diarrhea.

5 It is possible that a large intake of carotene is undesirable.

6 Under ordinary circumstances, sufficient quantities of vitamin A are provided by a diet in infancy which contains milk, cod liver oil from the second week of life, and vegetables from the fifth or sixth month.

ABSTRACT OF DISCUSSION

DR HENRI J GERSTENBERGER, Cleveland. Two years ago, Dr Clausen presented this subject at the American Pediatric Society meeting, and he felt then that there was correlation between a low carotene content of the serum and a high incidence of infection, and the disappearance of infection with a rise in the carotene content of the blood. I took occasion at that time to doubt the interpretation that carotene acted in this fashion, namely, as a precursor of vitamin A, for two reasons. First, I had had ample opportunity to watch infants over many years who had regularly had an adequate intake of cod liver oil notwithstanding, these infants got infections and some died. In the second place, keratomalacia, the pathognomonic sign of complete deficiency of vitamin A in the diet, is not seen in human beings in this country. At least I have never seen a case and I doubt whether there is any one here who has. At that time I stated that possibly carotene is of value to the human body in some other capacity than as a precursor of vitamin A. In today's contribution Dr Clausen follows a more conservative course and I am in accord with what he has said. I do not think there is any good evidence to show that a liberal intake of carotene is essential in the prevention of

infections in human beings. It may be that the intake of carotene is of value in other directions than in the prevention of keratomalacia. But the notion that it is always a good thing to fill up on carotene, I think, is erroneous. I have expressed myself similarly in connection with uncontrolled and excessive, and often unnecessary, ingestion of viosterol. Particularly do I think it a mistake to take a large amount. The plan should rather be to administer the smallest amount considered to be necessary. However, carotene, as a precursor of vitamin A, is a normal food constituent often present in liberal amounts and, therefore, something different from viosterol for carotene gets into the system physiologically through the gastrointestinal tract. And yet, Dr Clausen may be right when he suggests that too much carotene may be taken. If, for instance, one is going to eat vegetables in amounts to equal the large intake of carotene in a concentrated form, I think that the gastrointestinal tract will object, and that may be an indication that too much carotene is being consumed.

DR I NEWTON KUGELMASS, New York. Infections are too widespread to be prevented universally by a single substance. Bacteria are too heterogeneous to be buffeted by mere vitamin A. Dr Clausen has translated these obvious clinical facts from his blood studies of children with infection. But even such an approach presents the limitation of the value of vitamin A in resisting bacterial infection. The colorimetric determination of serum carotinoids gives no indication of the actual body storage of vitamin A. The serum content of isomers of carotene is as yet not clearly correlated with their leukoform, vitamin A, stored in the liver and in other tissues. The mechanism of transformation of carotene into vitamin A is as yet unknown. In fact, it may be that children susceptible to infection are unable to effect such a transformation of carotene into active vitamin A. Carotene has been found to be adequate in the blood of the new-born and yet without any reserve of vitamin A in the liver. Determinations of vitamin A stored in the liver afford another approach in evaluating this problem. Thousands of livers examined post mortem revealed that 16 per cent of the population in Holland and 24 per cent of the population in England were deficient in vitamin A. The limitations of vitamin A as an anti-infective generally do not preclude its value specifically. The problem has been approached with the new-born. Their vitamin A storage is nil and yet they are immune to many infections. Their intra-uterine life requires no anti-infective agent. Colostrum has been found to be a rich source of vitamin A, but the hygienic care after birth does not even necessitate such provision. It has been found that large doses of carotene do not protect against infections of the upper respiratory tract but I have been impressed with the value of vitamin A in diminishing infections of the upper respiratory and intestinal tracts in 250 controlled children with malnutrition, chronic intestinal indigestion, bronchial asthma and hay fever, respectively, wherein the vitamin A intake has necessarily been deficient. I have concluded that vitamin A possesses no systemic anti-infective action but rather local tissue defense of such organs as the eyes, lungs and intestine. Vitamin A inadequacy in these secondary nutritional problems produces keratinization which leads to infection. Vitamin A thus increases differential permeability of membranes rather than affecting immunologically diverse bacteria.

Heredity and Cancer—The principal weakness in studies of individual families upon which many writers base their opinions is that the families so studied are usually ones which have shown a marked tendency toward cancer, and thus come to the attention of the student. There are unquestionably families which show a strong predisposition to the disease, but these are rare in proportion to the total population and too much weight is frequently given to the testimony from their study. The main question to be considered is: Are persons who have a family record of deaths from cancer any more likely to die from that disease than those without such a history? So far there has been no conclusive proof that a person with one cancer death in the family, either a parent or a brother or sister, need fear a predisposition to the disease.—Hunter Arthur. *The Inheritance of Cancer in Mankind*, *Am J Cancer* 19 79 (Sept.) 1933.

FAVISM

REPORT OF A CASE

THOMAS McCRAE, MD, FRCP (LOND)

AND

J C ULLERY, MD

PHILADELPHIA

Favism (fabism) is a syndrome caused by inhalation from bean plants when in blossom or by ingestion of the beans (*Vicia fave*) and characterized by an acute febrile anemia with jaundice, hematuria and hemoglobinuria. It occurs most frequently in Sicily and southern Italy, and most of the reports are found in Italian literature. We have not been able to find a report in American or English literature. It is possible that cases have been reported under another designation.

REPORT OF CASE

History—Dec 12, 1932, J C, a white man aged 53, was admitted to the Pennsylvania Hospital in a serious condition. He had a ghastly appearance due to a combination of jaundice and a curious ashen gray color, particularly of the face. He showed extreme weakness and complained of frequency of urination and the passage of black urine. Lesser complaints were of anorexia and constipation. He was intelligent and able to give a clear history. Dec 7, 1932, he had eaten a very hearty meal, one of the principal constituents of which was cooked beans, of which he had taken a large amount. An hour after the meal he began to feel marked weakness and was compelled to lie down. Two hours later he voided urine and noticed that it was very black. From this time until his admission to the hospital he was compelled to be in bed, the passage of black urine had continued and there had been marked frequency of urination, usually about ten times in the twenty-four hours. December 7 he had taken a large dose of epsom salt and stated that blood was present in one of the stools after this. Shortly after the onset he began to have pain in the back, which had been constant. His weakness had increased markedly and since the second day of his illness he had not been able to get out of bed. On December 10, jaundice was noted for the first time and this apparently increased rapidly.

The patient volunteered the statement that he had similar attacks during his childhood in Sicily and associated his present illness with these. At the age of 7, while walking in the country, he passed a field of plants in full bloom. Soon after this he began to feel dizzy and weak, and he was able to walk a short distance only when he lost consciousness. He was found lying on the ground and was carried home regaining consciousness later in the day. Following this he passed bloody urine for three or four days and felt marked weakness for about ten days, after which he recovered his usual health. He stated that he had identical attacks each year from the age of 7 until he was 14, having one attack each year under the same circumstances. On each occasion he lost consciousness but did not know the exact duration of unconsciousness until the last attack when he was told that it persisted for fifteen hours. He came to the United States at the age of 14 and had had no similar trouble until his present illness. With the onset of this illness he at once recalled the experiences of his childhood and associated the beans which he had eaten with the plants which had affected him when in flower. He thought that the beans which he had eaten were the same as those which grew on the plants in Sicily.

In his past history there was nothing of significance otherwise. He apparently had scarlet fever in childhood. There was no history of malarial fever.

Examination—The patient presented a remarkable appearance. He looked very ill, there was a curious ashen gray color of the face and pallor of the mucous membranes with jaundice which was much more marked in the skin than in the sclerotics. The heart was found to be somewhat enlarged with a soft systolic murmur at the apex. The abdomen was flat and did not show any tenderness except on palpation of the liver. In

the right nipple line the edge of the liver was felt 3 cm below the costal margin and in the midline 4.5 cm above the navel. The spleen was not felt.

The temperature on admission was 99 F and rose rapidly to 101.6, in the next two days there was slight fever, which never reached 100, after which the temperature was normal. The pulse was 100 on admission, the blood pressure 112 systolic, 60 diastolic, and the respirations 24.

The amount of urine during the first twenty-four hours was 2,500 cc, it was absolutely black and the reaction was alkaline. It contained a moderate amount of albumin and large amounts of hemoglobin. There were some red blood cells but not a large number. There were a great many granular casts.

The blood examination showed hemoglobin 38 per cent, red blood cells 1,420,000, and leukocytes 19,300, of which 73 per cent were polymorphonuclears and 27 per cent small mononuclears. The red blood cells appeared to be normal on the first examination.

Course—The rapid improvement was remarkable. Two days after admission he felt much better and seemed to be stronger. The jaundice was distinctly less and the liver enlargement slightly less. By December 20 the jaundice had almost entirely disappeared and the edge of the liver could no longer be felt below the costal margin. The amount of urine varied somewhat, the average amount being from 1,500 to 2,000 cc. The specific gravity varied from 1.014 to 1.028. The hemoglobinuria continued until December 14, when the gross appearance showed it for the last time, and after this date no more red cells were found in the urine. Granular casts were present for a few days longer but albumin was not found in the urine after December 14.

The blood count rose rapidly. December 16, the hemoglobin was 42 per cent, red blood cells 1,900,000 and leukocytes 13,000. December 29, the hemoglobin was 74 per cent, red blood cells 3,540,000 and leukocytes 6,500. Reticulocytes were present in considerable numbers, 14 per cent. December 13, rising to 22.2 per cent, December 15, after this they fell to 10 per cent, January 5, and to 1.8 per cent, January 15. Within two days after admission the red blood cells showed considerable variation in size, and 11 nucleated red cells (normoblasts) were found for each 100 leukocytes. December 20, the variation in the size of the red cells continued and 4 nucleated red cells were found per hundred leukocytes. By January 6, the hemoglobin had risen to 83 per cent, the red blood cells were 4,200,000, and the leukocytes were 6,600. The red cells and platelets appeared perfectly normal.

The blood urea nitrogen, December 13 was 37.1 and creatinine 14, December 20, the figures were 18.6 and 1.2. The blood sugar shortly after admission was 72. The phenolphthalein test, December 20 gave 47 per cent in two hours. January 9, a second phenolphthalein test gave 60 per cent in two hours.

December 14, the blood showed beginning hemolysis at 0.36 per cent of sodium chloride and complete hemolysis at 0.32 per cent. December 16, hemolysis began at 0.40 per cent and was complete at 0.32 per cent.

No evidence of blood was found in the stools.

The patient's blood gave a very strong reaction to both the Wassermann and Kahn tests. As paroxysmal hemoglobinuria has been described as due to syphilis the Arneft-Landsteiner serologic test was done, January 12. Serum was obtained and mixed with normal red blood cells. The mixture was chilled for ten minutes and then brought up to body temperature in half an hour. After centrifuging the serum showed no hemolysis. This is found to be present in paroxysmal hemoglobinuria of syphilitic origin. The study of the spinal fluid gave normal results in every way.

The patient was discharged from the hospital, January 19, in very good condition. His color was good, the jaundice had entirely disappeared, and the urine was clear and absolutely normal. The heart was of normal size and the soft systolic murmur had disappeared. Neither the liver nor the spleen could be felt. The urine has remained clear since his discharge from the hospital and the blood count February 20 was normal.

Specimens of the beans which he had eaten were obtained and an extract of them was used for intradermal skin tests. These were first tried in a dilution of 1:100,000 but no reaction was obtained. Two days later the same tests were tried in a dilution

of 1 1,000 There was a definite local reaction with erythema and some elevation about the area. With this the patient complained of general malaise and dull aching pains in the lumbar region, which began about two hours after the test was done. The urine remained perfectly clear. It was four days after this test before the patient felt that he had returned to his previous condition and by January 14 he was able to be out of bed again. January 15, he was given another test, 1 cc of 1 1,000 being given intradermally. There was the same moderate local reaction and again he complained of lumbar pains and general malaise. In two days this disappeared.

COMMENT

This disease or syndrome has been known from ancient times and is mentioned in the works of Herodotus, Pythagoras and Empedocles. The modern study dates from about the middle of the 19th century. It was early recognized that the disease might occur in those who had the idiosyncrasy if they came near a field with the plants in bloom or ingested a very small quantity of the beans. As the disease occurs principally in Sicily, Sardinia and some of the southern provinces of Italy, it is natural that nearly all the articles dealing with it are written by Italian observers. An excellent description is given by Gasbarrini.¹ References in English literature appear to be very few. In the German literature it is termed fabismus.

ETIOLOGY

Heredity plays a part in some cases and has been reported in 20 per cent of some reported series. There are reports of families in which every member for several generations has been affected and in such families the disease is said to be severe. The susceptibility varies greatly in the individual. Some who have eaten the beans with impunity for years suddenly show the idiosyncrasy and later become free from it. The first attack may occur in adult life or old age. The disease has occurred in nursing infants when the mother has eaten the beans. In some such cases the mother is not subject to favism.

It occurs at any age, but young children and adults are affected more often than youths or the aged. Sex apparently has no influence.

Malaria and syphilis have been suggested as having an influence, but there is no evidence to support this.

In a series of 1,211 cases of favism, 459 (38 per cent) were due to inhalation by being near the plants in bloom and 725 (62 per cent) were due to ingestion of the beans, raw or cooked. Ingestion of fresh beans seems to be the cause more frequently than eating cooked beans. It is stated that the gastro-intestinal features are usually more severe from eating cooked beans.

In a locality where the disease occurs, the prevalence may vary from year to year. At one time there are isolated cases and in another year it may almost be described as epidemic.

PATHOGENESIS

There has been a great deal of discussion and various opinions. There is no agreement as to whether the effect is more marked with the fresh bean or the dried beans. An anaphylactic action has been obtained in animal experimentation, the animals having previously been sensitized. There are difficulties in any explanation. Of the people who eat the beans in the raw state or inhale the pollen, only a small proportion develop symptoms, and the point is emphasized that there is no

relation between the amount of beans ingested or the pollen inhaled and the severity of the symptoms. Death has resulted in individuals who have been exposed to a very small amount. When eaten, the bean protein may enter the circulation because of an abnormal permeability of the intestinal wall or from lack of digestive power, possibly some disturbance in the liver causes hypersensitiveness and then anaphylactic shock.

THEORIS

It has been suggested that the disease may be due to foreign substances, such as a fungus, but there is no proof of this. In animals a condition of hypersensitiveness and anaphylactic shock can be produced by feeding the beans or by injecting the protein of the bean first and later feeding the beans. There is evidence that the disease rarely occurs in persons who eat the beans regularly but often occurs after the first time the beans are eaten in a given year. The general opinion is that the syndrome represents a hypersensitiveness to the protein of the bean and that the manifestations are due to an anaphylactic reaction.

The symptoms caused by inhalation of the pollen are apparently identical with those due to eating the beans. Apparently the amount of protein inhaled has very little influence. It is pointed out that in this particular plant the pollen is rather sticky, which interferes with any wide dissemination.

The reports of pathologic examinations are very few. The death rate is given as about 8 per cent in Sardinia. In a certain number of cases, death occurs in from two to three days, apparently from the severe anemia.

CLINICAL FEATURES

The incubation period is given as from two to six hours when due to inhalation from the plants in flower and from one to two days following the ingestion of the beans. In our patient this period was much shorter, as the attacks of unconsciousness from inhalation occurred when he was quite close to the fields, and within an hour from ingestion of the beans in this attack.

The symptoms at onset are fever, sometimes with chills, often vomiting, marked weakness and a sense of oppression, twitching, vertigo, ringing in the ears and unconsciousness in many cases. All writers comment on the marked pallor and the rapid onset of jaundice which usually increases to the third day. Usually within an hour after the onset large amounts of bile are found in the urine. The statement is made that the jaundice is never deep, but in our patient it was marked. The most dramatic occurrence is the passing of bloody urine, which occurs very promptly and which may clear very rapidly. The fever varies greatly. It is usually irregular but may be continuous and rarely goes above 103. The termination is usually by lysis. The digestive symptoms do not always occur and seem to be more common in children. There may be nausea, vomiting and diarrhea. When death occurs, it apparently has resulted from the severe anemia. In the majority of the cases the liver is somewhat enlarged and tender. Emphasis is laid on the fact that enlargement of the spleen is usually a very constant feature, but occasionally it is lacking.

In the regions where the disease is prevalent, malaria is common and many patients have a chronically enlarged spleen. In our patient there was no enlargement of the spleen to be made out. Hemoglobinuria appears in from a few hours to a day after the inhalation.

¹ Gasbarrini. Il favismo. Policlinico 22 1505 and 1537 1915.
Preti L. Klin. Wchnschr. 6 2429 1927.

tion or ingestion and may last for three or four days. It usually disappears very rapidly. Apparently there is usually a decreased amount of urine and in very severe cases there may be anuria for a time. In our patient the output of urine was not diminished. The urine apparently never shows any hemolytic effect on the patient's red blood cells or on those of a normal individual.

BLOOD

The decrease in the number of red cells may be so rapid and so marked that the patient rapidly dies, with a blood count of about 1,000,000 and the hemoglobin about 20 per cent. At the onset there may be leukopenia, the neutrophil cells being reduced, and this is followed by leukocytosis, which is practically always present. It is stated that the blood platelets are very few at the onset and later on are present in much larger numbers than normal. Some consider that the increase in the platelets suggests a favorable prognosis. The resistance of the red blood cells does not seem to be particularly altered, and auto-agglutination of the red blood cells has never been found. The occurrence of hemoglobinemia is not constant. Apparently the blood serum of patients with favism has no hemolytic action either on the patient's blood or on that of normal persons. The injection of blood serum from a patient has produced hemoglobinemia with leukocytosis in a rabbit, but this is not a constant result.

Various forms are described varying from abortive attacks to what may be described as a malignant form. The abortive type may follow exposure to a field of plants in bloom, or it may be caused by the ingestion of a few beans, with dizziness as the most prominent symptom.

Usually in from two to four days the symptoms decrease, the hemoglobin and bile pigments disappear from the urine, urobilin may be present for some time. The blood condition improves rapidly. In some cases, tachycardia persists for a time.

The condition is apparently a true hemoglobinuria. The marked breaking down of the red cells accounts for the extreme anemia. It is suggested that the enlargement of the liver and perhaps of the spleen also results from the rapid hemolysis.

DIAGNOSIS

The diagnosis should be made without difficulty in regions where the disease usually occurs. Elsewhere cases must be unusual, and without some clue the diagnosis is difficult unless some lead is given by the patient, as in the present case. The picture of fever, severe anemia, jaundice and hemoglobinuria is unusual and the possible causes are not many. Malarial fever with hemoglobinuria should be readily excluded and the history of consumption of beans, if asked for, should be readily obtained. Paroxysmal hemoglobinuria shows a specific autolysis in the blood by the Donath-Landsteiner test, which is absent in favism and the general features are not as severe. Slight or abortive forms of favism may be very difficult of diagnosis.

TREATMENT

In the early stages the shock may be very marked, for which epinephrine gives good results. For severe anemia blood transfusion is necessary, otherwise the treatment is symptomatic. Large doses of iron are indicated.

Clinical Notes, Suggestions and New Instruments

CONGENITAL CIRSOID ANEURYSM OF THE LEG

MONT R. REID, M.D., CINCINNATI
AND

HERBERT G. CONWAY, M.D., NEW YORK

Among the conditions that can have the effect of causing an overgrowth of an extremity during the growing period of life may be mentioned chronic osteomyelitis and abnormal arteriovenous communications. This effect is apparently due to an abnormal increase of the arterial blood supply.

An increased length of the limb resulting from abnormal arteriovenous communications has been reported by Giraldez,¹ Cordonnier,² Davis,³ Hewett,⁴ Franz⁵ and Reid.⁶ In four of the cases reported by these authors the etiology of the condition was trauma, while in two cases it was congenital. In a congenital case,⁶ in a woman, aged 36, the affected leg was 6 cm. longer than the normal leg.

These cases have been reported under the various titles of abnormal arteriovenous communications, arteriovenous aneurysm, cirsoid aneurysm, racemose aneurysm and pulsating angioma. In all instances the cause has been abnormal communications between the arteries and veins. The most com-

Fig. 1.—Lateral view of legs showing increased length and increased diameter of right leg caused by cirsoid aneurysm.

monly used term is that of cirsoid aneurysm and, for that reason, we have chosen it as the title for this report.

A white girl, aged 1 year, was admitted to the Children's Hospital because of an abnormal enlargement of the right leg, associated with pulsation of the extremity and an indolent postoperative ulcer of the leg.

Three weeks after delivery the mother noticed a small area of bluish discoloration over the posterior aspect of the lower third of the infant's right leg. This was attributed to a bruise. A few days later the observation was made that the affected extremity was longer and of greater diameter than the opposite one. This observation was confirmed by a physician's measurements. Five weeks after birth the baby developed the classic signs and symptoms of pyloric stenosis for which a Fredet-Rammstedt operation was performed. Convalescence from this operation was uneventful except for the steady increase in the size of the right leg. At this time the superficial veins of the extremity were enlarged and could be seen.

From the Department of Surgery of the University of Cincinnati College of Medicine and the Surgical Department of the Children's Hospital, Cincinnati.

to pulsate. The skin over the thigh and calf was described as quite tense and shiny.

When the patient was 3 months old Dr Roy D McClure operated on the extremity, ligating a number of arteriovenous communications through an incision over the posterior aspect of the calf. Following this operation the size of the right leg did not change. A second operation in this location was carried out by Dr McClure when the baby was 6 months old.

When seen by us, the patient was 1 year old. Physical examination was essentially negative except for the right leg. The heart borders were apparently within normal limits, the lungs were normal, rectal temperature was 100.4 F. Examination of the right leg showed that it was distinctly larger than the left.

Results of measurements are given in table 1.

TABLE 1—Measurement at 1 Year

Circumference	Right	Left
At trochanter	34 cm	23 cm
Of upper third of thigh	31.5 cm	21 cm
Of lower third of thigh	25 cm	18 cm
At knee	25 cm	16 cm
Of upper third of leg	24.5 cm	14.5 cm
Of middle third of leg	23 cm	13 cm
Of lower third of leg	23 cm	13 cm
Of foot (near heads of metatarsals)	15 cm	12 cm

The entire right leg was palpably warmer than the left. Large inguinal nodes were felt on the right side these varied from 1 to 2 cm in diameter and were very discrete and firm. Over the dorsal aspect of the lower third of the leg there was a shallow ulcer, 5 by 8 cm. The skin about its edges exhibited a bluish discoloration. A marked systolic bruit was heard in the popliteal space, over the entire leg and also over the large veins on the inner aspect of the thigh. On digital compression of the femoral artery in the groin the entire extremity decreased in size and became pale.

Röntgenograms showed an increased length and diameter of all the bones of the right leg, and a tele-röntgenogram of the chest showed some increase of the outline of the heart to the left.

In the first six weeks of our observation the leg increased slowly but steadily in size and the ulceration over the lower part of the leg increased in extent. Intercurrent parotitis had caused operative procedures to be delayed. Measurement at this time demonstrated the rapid increase in the size of the leg (table 2).

At this examination the continuous bruit could be heard all over the large vessels on the femoral vessels caused no change in the size of the leg and no pallor. The skin over the leg had now become tense and shiny, and there was intense local heat in the thigh and region of the calf.

May 12 1931, under ether anesthesia, Dr Reid made a low inguinal incision and ligated the femoral vein above Poupart's ligament. An occlusive Halsted aluminum band was applied

to the femoral artery in the same location. It was estimated that the artery and vein were approximately three times the size of the normal vessels of a 14 months old infant. Two large lymph nodes were removed for microscopic study and presented only endothelial hyperplasia.

Following the operation the leg became softer, cooler and smaller, though the bruit was still audible over the calf and thigh. The skin over the leg below the knee took on a more mottled appearance. Postoperatively the child developed lobar

Fig 3—Section from tibialis anterior muscle showing dense vascular network.

pneumonia at the base of the right lung from which she promptly recovered. During the next four weeks there was a slight fever, the rectal temperature varying from 100 to 102 F. The bruit diminished in intensity over the thigh and completely disappeared from the region of the calf. This was interpreted as evidence of thrombosis of vessels subsequent to infection about the ulcerated wound on the posterior aspect of the calf. Because of the extent of the circulatory embarrassment in the extremity and the rather rapid progress of the infected ulceration, amputation was considered necessary.

TABLE 2—Measurement at 1 Year and 6 Weeks

Circumference	Right	Left
At trochanter	34 cm	23 cm
Of upper third of thigh	31.5 cm	21 cm
Of lower third of thigh	25 cm	18 cm
At knee	25 cm	16 cm
Of upper third of leg	24.5 cm	14.5 cm
Of middle third of leg	23 cm	13 cm
Of lower third of leg	23 cm	13 cm
Of foot (near heads of metatarsals)	15 cm	12 cm

June 11, under ether anesthesia, Dr Reid performed a mid thigh amputation using two tourniquets, one above and one below the level of incision, so that when the extremity was elevated the infected material from the large venous sinuses of the extremity did not drain down into the operative field. This technic of the application of two tourniquets for leg amputation is described elsewhere.

The child had an uneventful convalescence and was sent home from the hospital shortly after operation, with a well healed amputation stump. No bruit could be detected after the amputation. The child has remained well and shows no evidence of the original vascular lesion developing in the stump.

The removed leg measured 23 cm from the patella to the os calcis and 7 cm from the amputation line to the patella. Motion of the knee joint was not limited. Over the middle and lower thirds of the posterior aspect of the leg was a deep ulceration measuring 5 cm transversely and 9 cm in length. Its base was formed of unhealthy, pale granulation tissue.

superimposed on pale, edematous and hyalimized gastrocnemius and soleus musculare Minute vascular thromboses were seen in this region The anterior aspect of the leg presented musculature that exhibited a spongy appearance and numerous vessels that resembled an angioma Fixation of the specimen allowed for its section transversely into disklike sections, from which tissue was taken for microscopic examination The photomicrographs showed venous dilatation thrombosis and great abundance of blood vessels

AUNT JEMIMA BUCKWHEAT, CORN AND WHEAT FLOUR

Manufacturer—The Quaker Oats Company, Chicago

Description—Self-rising pancake flour containing buckwheat, corn, and wheat flours, powdered skim milk, corn sugar, soda, calcium acid phosphate and salt

Manufacture—The flours are heat processed and bolted The ingredients are mixed in definite proportions in a batch mixer, bolted and automatically packed in cartons Each batch is subjected to a baking test

<i>Analysis</i> (submitted by manufacturer) —		per cent
Moisture		9.6
Ash		6.3
Fat (ether extraction method)		1.9
Protein (N \times 6.25)		11.2
Crude fiber		1.2
Carbohydrates other than crude fiber (by difference)		69.8
<i>Calories</i> —3.4 per gram 97 per ounce		

MCCORMICK'S BEE BRAND MACE

Manufacturer—McCormick and Company, Inc., Baltimore

Description—Ground mace (dried arillus of *Myristica fragrans* Houtt)

Manufacture—The arillode, or covering of the nutmeg is removed either by stripping with a knife or by hand, dried on mats in the sun, exported in wooden cases, and ground and packed in tins at the packing plant

<i>Analysis</i> (submitted by manufacturer) —		per cent
Moisture		9.7

Claims of Manufacturer—Conforms to the United States Department of Agriculture standard

AMBROSIA CREAM CORN MEAL

Manufacturer—Texas Star Flour Mills Galveston Texas

Description—Finely granular white corn meal practically free from corn germ and bran

Manufacture—White corn is cleaned by the usual grain cleaning methods to remove foreign material and is tempered with live steam to loosen the bran and germ from the endosperm and enable separation of the latter by scouring and aspiration methods The endosperm or corn grits are ground and graded and remaining bran or germ is removed endosperm

of a uniform fine granular size is properly dried and packed in sacks

VITAMIN A, CAROTENE AND COUGH DROPS

At the recent session of the American Medical Association, in a discussion before the Section on Gastro-Enterology and Proctology, Gorham¹ said "The subject of vitamins and their relation to the so-called deficiency diseases has become so complicated that most of us are unable to follow the course of events related to this field with any degree of orientation." Vitamin D and irradiated ergosterol were at first the subject of widely varying claims and counter-claims. Today the advantages and limitations of the vitamin D carrying substances are rather well established. Now confusion and exaggeration distort our views of vitamin A and its precursor carotene. Some manufacturers promote vitamin A and carotene products without regard to lack of substantiation for the claims that are made.

From the accumulating investigative evidence it seems almost certain that carotene may be converted in the liver to vitamin A. Thus all the claims of physiologic activity for vitamin A are transferred to carotene—the provitamin A. Manipulators of scientific diction promptly termed carotene "primary vitamin A" and vitamin A as known, "secondary vitamin A." The result is merely more confusion and chaos in scientific literature.

Opinions vary as to the value of vitamin A, in the diet both of the well and of the sick. Some investigators have applied the term "anti-infective" to fat-soluble vitamin A, because an experimental animal, deprived of vitamin A, is susceptible to infection. However, the usefulness of administering vitamin A preparations as a means of preventing respiratory infections in human beings is far from established. The Council² authorized the following statement on this subject at its last annual meeting:

The Council has required that no advertising submitted to it for vitamin A preparations should be permitted to go beyond

the claim that vitamin A is an aid in building up resistance that mention of specific diseases or implied reference to respiratory diseases by mention of lowered resistance due to wet weather, drafts, etc., is objectionable. The Council's referee pointed out that controlled experiments in a large clinic had afforded no evidence to show that the use of cod liver oil or other vitamin A preparations caused a lower incidence of respiratory diseases.

But a few years ago ultraviolet irradiation—or the vitamin D effect—was claimed to be a valuable protective agent against respiratory diseases. Clinical evidence (particularly on infants and children) under controlled conditions failed to demonstrate that this agent was of decided benefit in this respect. Hess and his co-workers³ recently reported the results of a careful study of the use of vitamin A in respiratory diseases. The vitamin A was given in the form of cod liver oil and halibut liver oil, also employed was an oil solution of carotene. These studies indicate that in respiratory infections there is no difference, under controlled conditions, between groups of children receiving vitamin A in fish liver oils or provitamin A (carotene) and control groups not thus supplied. It was concluded that there is no clinical basis for designating or considering vitamin A as the anti-infective vitamin. Furthermore, there seems to be little evidence of any widespread deficiency of vitamin A in the national dietary, according to a questionnaire widely circulated by these New York investigators. Still more recent work confirms the conclusions of Hess and his associates. Elsewhere in this issue, Clausen and McCoord⁴ of Rochester, N. Y., report further on the limitations of the anti-infective value of provitamin A (carotene). A chemical method of determining the relative carotinoid content of the blood in human beings was employed. These investigators found that in severe infections the amount of carotinoids was below normal, but they contend that a lower level of carotinoids cannot be considered as preceding, or predisposing to, the infections, but, rather, as a consequence to the infection. This lowering may be due to any of three causes: (1) more rapid utilization in fever, (2) slower absorption, and (3) poor appetite. They found that when the carotinoid content of the blood was increased appreciably above normal, susceptibility to infection rises. This suggests a possible injurious action of excessive carotene intake and bears out the warning made last spring by the Council on Pharmacy and Chemistry² in reference to this question. The Rochester investigators emphasize the fact that children over the age of 2 years are likely to receive a diet containing a sufficient amount of vitamin A and that a relatively small percentage of recurring respiratory infections can be attributed to a low intake of carotene. They further conclude that during the period of rapid growth in experimental ani-

² Annual Meeting of the Council on Pharmacy and Chemistry. J. A. M. A. **100** 1402 (May 6) 1933.

mals, adequate amounts of vitamin A are needed. If vitamin A is withheld during rapid growth, the tissues are so altered that resistance to infection is low. If vitamin A is present during this period, the organism may subsequently be depleted of its stores of vitamin A without developing a marked loss of resistance to certain infections. When rapid storage of vitamin A is desired, halibut liver oil, or cod liver oil, would seem more suitable than preparations of carotene, because of the more rapid absorption of vitamin A than of carotene. Carotene is poorly absorbed in the presence of fever or diarrhea. In these views they are in agreement with Hess and his co-workers. Clausen also makes the statement that "under ordinary circumstances, sufficient quantities of vitamin A are provided by a diet in infancy which contains milk, cod liver oil from the second week of life, and vegetables from the fifth or sixth month."

The foregoing discussion is of special interest at this time in view of the recent announcements that the S M A Corporation has agreed to supply carotene—regrettably called "primary vitamin A"—to the manufacturers of Smith Brothers Cough Syrup and Cough Drops (*Ding Trade News*, Oct 3, 1933). The products are now being heralded in extravagant advertisements in street cars. One hardly anticipates scientific accuracy from the promoters of so-called cough drops. One does anticipate that nostrum promoters will continue to avail themselves of pseudoscience to promote sales. The observations of Hess, Clausen, and others show that there is no scientific basis on which any claim can be made for the rationality of including vitamin A in a cough syrup. *THE JOURNAL* knows of no evidence that the S M A Corporation or the manufacturers of Smith Brothers Cough Syrup and Cough Drops have developed to show whether or not the carotene in cough drops maintains its potency, whether there is danger of carotene poisoning from the use of unlimited amounts of such products, or whether the amount of carotene claimed to be present is as effective in Smith Brothers Cough Drops as in milk. There is nothing to show the alleged advantage of adding vitamin A to cough syrup. Certainly there is no evidence, so far, that it relieves cough. There is danger in dependence on such nostrums in the loss of precious time by those suffering with respiratory disorders who have been misled by this propaganda.

No manufacturer of integrity, no firm with the prestige and background of the S M A Corporation can afford to be associated with such meretricious quackery, whatever the financial return. The chief value of any cough drop is to keep one's mouth shut—and to yield a demulcent effect. For this purpose there are hosts of preparations on the market, sold without the hocus focus and propaganda now connected with the so-called non-infective vitamin. In the past *THE JOURNAL* has criticized other ethical manufacturers for making their

manufacturing facilities available to promoters of patent medicines and nostrums. For some centuries the world has looked askance at those who let not the right hand know what the left hand doeth. The vicissitudes of the depression have driven many into strange and alarming relationships.

MR KINGSBURY SPEAKS FOR THE MILBANK FUND

In the annual report of the Milbank Memorial Fund for 1932, just made available, the secretary of that fund pays his respects to the attitude of the medical profession in relation to the final report of the Committee on the Costs of Medical Care. Mr John A. Kingsbury recognizes that the committee failed to propose a comprehensive plan which would solve the basic problem with which it was concerned. He says

This failure, cannot be ascribed wholly to a lack of vision or of courage on the part of all of its members, in all fairness, it should be said that much of the fault lay with obstructionists' tactics on the part of certain groups of physicians who generally control medical organizations and often are able to use the great prestige of these organizations to prevent, rather than to promote, the delivery of adequate medical services to all of the people. Such an attitude is difficult to understand at the moment since it is obvious that no solution will meet the underlying problems of providing medical care to all of the people which does not, at the same time, provide better facilities for scientific medicine as well as higher compensation for the rank and file of physicians which does not safeguard the confidential relationship between patient and doctor, and which does not guarantee the freedom of choice of physician to the patient and full scope, for the physician, for private practice among that portion of the population which can afford to pay for it. But looking at the history of medicine and public health in perspective such an attitude is not so strange as it appears, it has characterized the practice of medicine for centuries. As in other instances, when the public good becomes predominant this phase of medicine will pass and a comprehensive plan will emerge and will be adopted.

Proceeding in his discussion Mr Kingsbury says that some plan for conservation of the people's health on a national scale ought to be given immediate consideration. The report calls attention to lowered appropriations for the public health service in some states and finally says that in Indiana the state department of health has been virtually abandoned. The medical profession will, of course, appreciate the implied compliment in Mr Kingsbury's realization of the fact that medical leaders successfully opposed the plan of this foundation in cooperating with some others to put over, through the Committee on the Costs of Medical Care, a proposal for a form of standardized medical practice in the United States, leading eventually to state medicine. The medical profession realizes that in voicing his views Mr Kingsbury is simply obeying his master's voice. Mr Alfred G. Milbank himself, in an address recently came out definitely for state medicine as the objective sought. One wonders however, what the governor of Indiana and the health officials of that state will understand when they read Mr Kingsbury's statement that their department of health has been aban-

done. What actually has occurred is a consolidation in the interests of economy and an attempt to bring the medical profession more closely into proper relationship with the public health service. Moreover, there has been the usual resentment by those who have been displaced at those who supplanted them. The evidence thus far available as to the functioning of the department of health of the state of Indiana indicates already a considerable improvement in efficiency in some departments.

These announcements by Mr. Kingsbury emphasize significantly the menace to medical practice inherent in some of the philanthropic interests that have invaded the medical field. Sooner or later these executive secretaries must realize that the right to say how medicine shall be practiced must remain with the medical profession. The type of interference and propaganda promoted by Mr. Kingsbury through the Milbank Memorial Fund is good warrant for the phrases "the curse of philanthropy" and "misguided philanthropy," which have been applied to some of his activities. Perhaps the physicians of this country and public health officials would today be working together more harmoniously and to better effect for the public good had not the situation been confused, muddled and mishandled through demonstrations, publicity and unwarranted propaganda arising from these extraneous forces.

"MEN IN WHITE"

The American stage witnesses, with the opening of this season, what appears to be a remarkable success for a play devoted wholly to a medical subject. "Men in White," written by Sidney Kingsley and produced by the Group Theater in New York, is devoted to life in a hospital. The program itself contains a copy of the Oath of Hippocrates. Briefly, the play concerns a resident physician, a chief of staff, a young woman to whom the resident physician is engaged, a nurse, and numbers of patients, other physicians and nurses whose lives revolve about those of the leading characters. Unlike many other plays devoted to medical topics the drama of this one is so outstanding that it affords not only an insight into the medical point of view but also an intense and interesting evening.

At the very opening of the play the chief of staff in the hospital postpones an operation because he feels that the patient has a good chance for recovery if treated medically. In the library of the hospital there is much discussion among the interns and visiting physicians as to the great advances that medicine has made in recent years and the necessity for continuous reading if one wishes to keep abreast of progress. Incidentally, *THE JOURNAL* occupies a significant place in this library. Gradually the theme of the play develops. The chief of staff, Hochberg, points out to the resident physician, Ferguson, the tremendous demands that medicine makes on the young man who chooses it as a

career. He indicates the need for study abroad and for a long apprenticeship if one wishes to reach the medical heights. There is a significant scene in which a child, given an overdose of insulin, develops the shock associated with hyperinsulinism. The resident recognizes the true condition and prevents the administration of additional insulin, giving an injection of dextrose instead, thus restoring the child to consciousness. There is a glimpse of a physician who made an unfortunate marriage immediately after leaving the hospital and who finds himself, six years later, struggling for a livelihood.

An extraordinary manifestation is the sustained applause by the audience, which, it is reported, occurs at practically every performance, as a recognition of the point of view of the medical profession relative to state medicine. Ferguson has been discussing with Dr. Levine the arduous career of the young man who enters medicine in this modern era.

Ferguson It wasn't much fun but, still I guess it's the only thing I really want to do
(Pause)

My dad used to say—"Above all is humanity!" He was a fine man—my dad. A small town physician—upstate. When I was about thirteen he came to my room one night and apologized because he was going to die. His heart had gone bad on him. He knew if he gave up medicine and took it easy he could live for twenty years yet. But, he wanted to go right on, wanted to die in harness—and he did.

(Pause)

Above all else is humanity. That's a big thought. So big that alongside of it you and I don't really matter very much. That's why we do it, I guess.

Dr. Levine You're right of course! Ah! It's not good—too much suffering! Kills things in you. A doctor shouldn't have to worry about money! That's one disease he's not trained to fight. It either corrupts him or it destroys him.

(He sighs.)

Well, maybe some day the State will take over Medicine!

Ferguson Then you'd get politics.

Levine That's the dilemma.

Ferguson Before we let the State control medicine, we'd have to put every politician on the operating table, and cut out his acquisitive instincts.

(Dr. Levine laughs.)

Levine That I'm afraid, would be a major operation!

Another remarkably significant scene is a meeting of the board of the hospital in which the medical staff fights off successfully an attempt by the lay board to secure money for the hospital through the manipulation of staff appointments.

Enough has been said to give the medical reader an inkling of the significance of this drama for the presentation of medicine in a proper light to the people. It must not be taken for granted that all the scenes show all physicians as demigods; instead, they are shown as human beings, some of them with failings which physicians, along with other people, sometimes reveal. But the play ends on a high note in which Ferguson accepts the call of his career as above family, friends and even his personal desires.

Current Comment

THE DOCTOR PRESCRIBES SHOES

According to some independent investigations made by a leading physician in the orthopedic field, there are listed in a shoe trade registry for 1932 a total of 189 trade names for shoes with the designation "Dr" as a part of the name. Here, obviously, is an attempt to capitalize a medical background in promoting these wares. The title "Dr" attached to the shoes would seem to indicate that they have been especially designed by a physician for certain types of foot weakness or malformation, whereas in the vast majority of cases the shoes were probably designed by a shoe manufacturer who then secured the consent of some unwary physician to the use of his name. Following the publicity accorded to the Canadian Mahlon Locke, the shoe sections in department stores in many parts of the country featured Mahlon Locke shoes, and advertisements in the newspapers suggested to readers the possibility of relief from arthritis by the wearing of this brand. Since every foot differs from every other one it should be at once apparent that no shoe constructed according to a standardized type could be quite adequate for any deformed or weakened foot. The specialist in orthopedic surgery is likely to prescribe supporting pads, braces or splints according to the conditions he finds after careful study, any other apparatus can be but a makeshift. It is to be hoped that the leaders in the boot and shoe manufacturing industry will, in developing their code for this industry, pay special attention to this type of misleading promotion. Moreover, physicians, particularly those specializing in orthopedics, should be aware of the manner in which their names may be misused in such a connection and avoid the possibility of having their names carried to posterity on the arches of some shoe rather than by their scientific contributions to the literature of their specialty.

THE BLOOD PRESSURE IN THE CORONARY ARTERIES

There is no part of the circulation more important than that in the coronary vessels. The fact that these vessels supply the heart with its nutrition and have irreplaceable functions owing to the circumstance of representing terminal arteries places these coronary structures in the forefront of interest to the clinician. More than two centuries ago it was assumed that the coronary orifices are occluded by the semilunar cusps during systole. If this were true, the circulation in the coronary system might be quite different from that elsewhere dependent directly on the cardiac systole. Thanks in particular to the investigations of the Harvard physiologist W. T. Porter the view became firmly established at the beginning of the present century that the systolic diastolic or mean pressure existing in the surface branches of the heart are practically the same as those in the aorta. About three years ago doubts were again expressed by European investigators. These conjectures have now been dispelled by Wiggers

and Cotton,² cardiologists at the Western Reserve University Medical School in Cleveland. Pressure pulses were simultaneously recorded from the aorta and either from the central end or from a lateral branch of the anterior descending ramus of the left coronary artery of the dog. The records, secured by the elegant modern technic using optical manometers, gave no indication that the pressure relations or form of the coronary pressure pulse are modified by any factor except the pressure changes in the aorta. The minor changes noted are such as occur in other branches of the aorta. An important phenomenon of cardiac function is thus again firmly established.

Association News

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks

The American Medical Association broadcasts on Tuesday and Thursday from 8:55 to 9 a. m., central standard time, over Station WBBM (770 kilocycles or 389.4 meters).

The subjects for the week are as follows:

October 31 Your Child's Teeth
November 2 Rickets

There is also a fifteen minute talk sponsored by the Association on Saturday morning from 9:45 to 10 o'clock over Station WBBM.

The subject for the week is as follows:

November 4 St. Vitus Dance

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CALIFORNIA

Southern California Medical Association—The fall meeting of the Southern California Medical Association will be in Los Angeles, November 3-4. The following program will be presented:

Dr. William W. Roblee, Riverside: The Bleeding Pregnant Uterus.
Dr. Andrew B. Wessels, San Diego: Frontal Lobe Abscess.
Dr. Alfred J. Scott, Jr., Los Angeles: Prophylaxis and Treatment of Certain Acute Infections in Children.
Dr. William D. Sansum, Santa Barbara: One Thousand Cases of Diabetes: Treatment with Higher Carbohydrate Diets.
Dr. John M. Askey, Los Angeles: Intuitory Cachexia (Simmonds Disease).
Dr. Clifford A. Wright, Los Angeles: Hemophilia.
Dr. David G. Christ, Los Angeles: Early Diagnosis and Treatment of Gout.
Dr. A. Bennett Cooke, Los Angeles: Practical Observation Based on 800 Thyroidectomies.
Dr. William Clifford McKee, Los Angeles: Hypertension and Pregnancy.
Thomas Hunt Morgan, L. D.: Prudent Heredity and Its Influence on the Practice of Medicine.
Dr. Hugh F. Freidell, Santa Barbara: Medical Management of Gall Bladder Disease.
Dr. Rafe C. Chaffin, Los Angeles: Illustrating a New Operation for Prolapsed Uterus.
Dr. Merrill W. Hollingsworth, Santa Ana: New Concepts in the Treatment of Syphilis.
Dr. Thomas Addis, San Francisco: Diagnosis and Treatment of Bright's Disease.
Dr. Paul B. Roen, Los Angeles: Practical Dietetics.

COLORADO

Society News—Dr. John Ruhrh, Baltimore, spoke before the Medical Society of the City and County of Denver, October 3, on poliomyelitis.—Speakers before the Boulder County Medical Society at Longmont, October 12, included Drs. Arnold

¹ Hochrein, M. and C. W. Arch. f. exper. Path. u. Pharmacol. 100: 11, 1933.

² Wiggers, C. J. and Cotton, F. S. Studies on the Coronary Circulation. I. The Coronary Pressure Pulses and Their Interpretation. Am. J. Physiol. 106: 9 (Oct.) 1933.

Minnig, Denver, on "Practical Application of Endocrines in Medicine", Richard W. Whitehead, Denver, "Laboratory Experiments in Endocrinology," and John Andrew, Longmont, "Malignant Tumor of Mediastinum"

DISTRICT OF COLUMBIA

University News—The monthly faculty seminar in George Washington University School of Medicine was presented by Dr. Earl B. McKinley on 'Etiology of Encephalitis with Particular Reference to Experimental Work on the Recent St. Louis Epidemic'—Prof. George Barger of the School of Medicine of Edinburgh gave the first lecture of the Smith-Reed-Russell series at George Washington University School of Medicine October 3, he spoke on 'Ergot and Ergotism' He also held a seminar on "Newer Developments Concerning Hormones"

FLORIDA

Sentenced for Selling Marijuana Cigaretts—Augustine Regalado, Tampa, the first person to be convicted in Hillsborough County of selling marijuana cigarettes in violation of the new state narcotic laws, was sentenced in criminal court to a year in the county jail, newspapers reported, October 6 His conviction was on a sale, August 2 and two other cases against him on alleged sales, July 27 and 31 were held in abeyance All the charges were made at the instigation of officials of the state health department, who appeared as witnesses

GEORGIA

Personal—Dr. Thomas H. Hancock, Atlanta, was presented with a forty year service pin by the Georgia Power Company, September 1 He is chief surgeon for the company —Dr. Donald T. Rankin, Milledgeville, has been appointed a member of the state board of medical examiners, succeeding Dr. Henry W. Birdsong, Athens, resigned

Society News—Dr. Daniel L. Seckinger, Atlanta, among others, discussed the treatment of malaria with atebirin (an amino-acridine derivative) before the Tri County Medical Society (Calhoun, Early and Miller counties) in Blakely, September 20 —Speakers before the Fifth District Medical Society in Atlanta, October 5, included Drs. Olin S. Cofer, on 'Treatment of Procidencia Uteri by the Vaginal Route', Daniel C. Elkin and James C. Sandison 'Experimental Hemothorax', James S. McLester, Birmingham, Ala. 'The Neurotic Patient,' and John Shelton Horsley, Richmond Va., 'The Pressing Problem of Cancer of the Stomach' —Dr. Mark S. Dougherty, Jr., presented a paper on anebiasis before the Fulton County Medical Society, September 21, and Dr. William C. Waters, Jr., a clinical talk on 'Respiratory Disturbances Due to Food Allergy' Dr. Carl C. Aven, Atlanta, gave a paper before the society, October 19, on 'Unique Thoracic Morbid States Simulating Ordinary Clinical Syndromes'

ILLINOIS

Society News—Dr. Richard B. Cattell, Boston, discussed cancer of the rectum before the Peoria City Medical Society, October 17 —Dr. Thomas B. Knox, Quincy discussed medical economics before the Greene County Medical Society, September 8, and Dr. Lee O. Frech, Decatur, the cost of medical care and the patient's ability to pay —At a meeting of the Crawford County Medical Society, Robinson, October 12, Dr. Herbert N. Rafferty, Robinson, spoke on acute osteomyelitis —Dr. Horace Kent Tenney, Jr., Madison Wis. discussed vomiting in the new-born before the McLean County Medical Society in Bloomington, October 10, and Dr. Lewis C. Scheffey, Philadelphia 'Gynecologic Problems of Interest to the General Practitioner' —Dr. William R. Cubbins, Chicago, addressed the Will-Grundy County Medical Society, Joliet, October 25 on intestinal obstruction —A clinic for the handicapped children of the county was conducted by Dr. Philip H. Kreuscher, Chicago, October 26 under the auspices of the Whiteside County Medical Society

Chicago

Personal—Dr. Edward F. Dombrowski has been placed in charge of Dunning State Hospital —Dr. Arno B. Luckhardt was elected an honorary fellow of the American College of Dentists in August He was also granted an honorary LL.D. degree by his alma mater, Conception College, Conception, Mo. —Dr. Abel R. Larrain has been appointed Peruvian consul in Chicago succeeding George Chavarri, resigned

INDIANA

Society News—Dr. John H. Warvel, Indianapolis, discussed diabetes before the Elkhart County Medical Society at Napance October 5 —At a meeting of the Fountain-Warren County Medical Society in Perrysville, October 5, Dr. Dudley T. Dawson, Danville, Ill., spoke on treatment of nervous and mental diseases —Dr. George W. Crile, Cleveland, addressed the Muncie Academy of Medicine in Muncie, October 3 on 'Treatment of Neurocirculatory Asthenia, Peptic Ulcer, Diabetes and Epilepsy by Denervation of the Adrenal Glands' —A symposium on advances in medicine was presented before the Clinton County Medical Society, in Frankfort, September 7, by Drs. Theodore A. Dykhuizen, Carroll A. Burroughs, Indianapolis, Robert A. Hedgecock and Bruce A. Work —Drs. Willis D. Gatch, George S. Bond and Thurman B. Rice, all of the University of Indiana School of Medicine, spoke before the Lake County Medical Society in Hammond, September 14, on etiology, diagnosis and treatment of peptic ulcer, angina pectoris, and the "Indiana plan," respectively —Dr. Albert M. Snell, Rochester, Minn., addressed the Tippecanoe County Medical Society at Lafayette, October 12, on 'Common Diagnostic and Therapeutic Problems of Hepatic and Biliary Disease' —Dr. William Muhlberg, Cincinnati, among others, addressed the semiannual meeting of the Union District Medical Association at Brookville, October 26, on "Medical Impairments from the Insurance Viewpoint"

IOWA

Physicians and Dentists Meet—The Pottawattamie County Medical Society and the Council Bluffs Dental Society held a joint meeting in Council Bluffs, September 21, with more than 100 in attendance The principal speaker was H. D. Coy, D.D.S., Hamburg, past president of the Iowa State Dental Society, whose subject was "The Relationship Between the Medical and Dental Professions" A symposium on focal infections was presented by the following

Dr. Harry N. Boyne, Omaha, Focal Infection in the Mouth
Dr. Sydney D. Maiden, Council Bluffs, Focal Infection in the Sinuses and Tonsils
Dr. Gerald V. Caughlan, Council Bluffs, Focal Infection in the Genito-Urinary Tract
Drs. Vincencius Stech and Eugene B. Fleresch, Council Bluffs, End Results of Focal Infection

Society News—Dr. Chevalier Jackson, Philadelphia, will address the Linn County Medical Society, October 31, on common diseases of the larynx from the points of view of the pediatrician and the general practitioner —The Austin-Flint Cedar Valley Medical Society was addressed, October 4, among others, by Drs. Howard L. Beye, Iowa City, on fractures, Robert D. Mussey, Rochester, Minn., obstetrics, and John C. Shrader, Fort Dodge, heart ailments The principal speaker at the evening session was Richard E. Scammon, Ph.D., Minneapolis, on the origin and early history of St. Bartholomew's Hospital of London —At a meeting of the Lee County Medical Society in Fort Madison, September 28, the speakers included Dr. George D. Jenkins, Burlington, on "Transurethral Resection of the Prostate" —Dr. Samuel J. Lewis, Columbus Junction, presented a paper on "Embolism of the Popliteal Artery" before the Louisa County Medical Society, September 14 —The Madison County Medical Society was addressed in Winterset, September 11, by Dr. Dwight C. Wirtz, Des Moines on 'Delayed Union or Nonunion of Fractures' Dr. Arnold L. Nelson, Winterset, demonstrated his method in the care of compound fractures of the digits —Dr. Clarence W. Baldrige, Iowa City, spoke before the Scott County Medical Society in Davenport, September 5, on "Functional Diseases of the Gastro-Enteric Tract" —The Tama County Medical Society heard Dr. Royal F. French, Marshalltown, discuss hospital work in India at its meeting in Toledo, September 8

LOUISIANA

Health at New Orleans—Telegraphic reports to the U. S. Department of Commerce from eighty-five cities with a total population of 37 million, for the week ended October 14, indicate that the highest mortality rate (182) appeared for New Orleans, and that the rate for the group of cities as a whole was 99 The mortality rate for New Orleans for the corresponding week last year was 149, and for the group of cities, 102 The annual rate for eighty-five cities was 108 for the forty-one weeks of 1933, as against a rate of 111 for the corresponding period of the previous year Caution should be used in the interpretation of these weekly figures, as they fluctuate widely The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate

MARYLAND

Survey of School Children—A survey of children in public and private schools in Baltimore is being conducted by Dr Humphrey Warren Buckler, at the request of the health commissioner of Baltimore. An average of 400 students are being examined daily by twenty physicians and 100 nurses.

Society News—The Baltimore City Medical Society heard a program presented by staff members of the Johns Hopkins University School of Hygiene and Public Health, October 20, as follows: Raymond Pearl, Ph.D., "The Inheritance of Longevity"; Dr Wade H. Frost, "Epidemiology of Diphtheria," and Elmer V. McCollum, Sc.D., "The Mineral Elements in Nutrition."

Laboratory Demonstration—Mr C. A. Perry, chief, bureau of bacteriology, state department of health, gave a demonstration of laboratory procedures used in the diagnosis and control of communicable diseases at a special meeting of the Carroll County Medical Society, recently. The use of the darkfield outfit in the diagnosis of syphilis, the proper method of swabbing a throat for cultures for diphtheria and of submitting the specimens for examination and the most effective method of collecting blood for agglutination tests were among the procedures demonstrated. The request from the society for this demonstration followed an inquiry made by the bureau of bacteriology into the use being made of laboratories by private practitioners. According to the bulletin of the state health department for October, similar demonstrations are planned for other county societies.

MASSACHUSETTS

Ether Day—The eighty-seventh anniversary of Ether Day was observed at the Massachusetts General Hospital, Monday, October 16. In the principal address of the day, Dr Leroy M. S. Miner, dean, Harvard Dental School, paid tribute to W. T. G. Morton, a Boston dentist, as the discoverer of the anesthesia. At the time of Morton's demonstration, it was not generally known that Dr Crawford W. Long, Atlanta, had previously used ether in an operation. The "Ether Dome" where Morton held his exhibition, is still preserved in the old main building of the hospital.

Graduate Courses—October 13 marked the opening of the first of a series of graduate courses to be given in Haverhill. Drs Chester M. Jones and Richard H. Miller, assistant professors of medicine and surgery, respectively, Harvard Medical School, Boston, directed the first course on practical medical principles. The courses will be given on successive Fridays and will cover the following subjects: vascular disease, arthritis, medical and surgical emergencies, syphilis and dermatology, gastro intestinal disease, pathologic pregnancy, vaccine therapy, diabetes and vitamins, and cancer.

MICHIGAN

Society News—Dr George A. Kamperman, Detroit spoke before the Oakland County Medical Society in Pontiac October 19, on "Toxemias of Late Pregnancy."—The Lenawee County Medical Society heard Dr Clarence H. Westgate, Morenci speak on the anemias October 10.—At a meeting of the Kalamazoo Academy of Medicine, October 17, Dr James H. Hutton, Chicago, spoke on "Clinical Applications of Recent Progress in Pituitary Physiology and Preparations."—Dr Wingate Todd Cleveland, spoke on "Royal Mummies" before the Wayne County Medical Society, Detroit, October 16. The surgical section of the society conducted a symposium on burns, October 23 as a memorial meeting to the late Dr Edward C. Davidson, who developed the tannic acid treatment for burns.—At a meeting of the Maimonides Medical Society in Detroit, October 17, Drs Solomon G. Meyers and David J. Sandweiss gave a resume of the recent advances in gastro enterology.—Dr William J. Stapleton Jr. Detroit addressed the Livingston County Medical Society at Howell, October 6, on malpractice.

MINNESOTA

Southern Minnesota Meeting—Dr Monte C. Piper, Rochester, was chosen president of the Southern Minnesota Medical Association at its annual meeting September 26 succeeding Dr Rasmus A. Williams Rushford. Vice presidents elected are Drs Sidney A. Slater, Worthington and Warner G. Workman, Tracy and secretary-treasurer Dr Harold C. Hahn, Rochester. Lloyd A. Whitesell of the University of Minnesota was awarded the \$100 prize for the greatest proficiency during his senior year and Harold F. Buckstein now

an intern at Receiving Hospital, Detroit, was given a medal for proficiency during his senior year. Speakers included Drs William J. Mayo, Rochester, Walter A. Fansler, Minneapolis, surgical treatment of hemorrhoids, Samuel A. Weisman, Minneapolis the shape of the chest in health and tuberculosis, Tobias L. Birnberg, St. Paul, eczema in infancy and childhood, and Charles J. Plonske, Faribault, psychology and treatment of fear. The Redwood-Brown Counties Medical Society acted as host and Dr Albert Fritsche, New Ulm was toastmaster at the banquet. Dr Walter H. Valentine, Tracy, was voted a medal for the best paper, an address on gunshot wounds in the abdomen.

MISSISSIPPI

Children to Be Tuberculin-Tested—School children of Clarksdale will be tested for tuberculosis, according to the state board of health. When needed, follow-up physical examinations and roentgenograms will be made. Each year, the board reports, several children in the Clarksdale schools develop active tuberculosis. Dr Mildred S. Fatherree, Sanatorium local physicians and the Coahoma County Health Department will cooperate in the work.

MISSOURI

Health Department Takes Over Milk Station—The Kansas City Health Department has taken over the Mother's Milk Station, Kansas City, effective September 16. Since its establishment in the Kansas City General Hospital in 1929 by the hospital committee of the Woman's City Club, the station has been operated by the club, with the cooperation of the Jackson County Medical Society. During the four and one half years of its existence, it has distributed 24,894½ ounces of milk, and 132 infants have been referred by fifty-five physicians.

Society News—At a meeting of the Jackson County Medical Society, Kansas City, October 24, speakers were Drs. Herbert J. Rinkel, on "Migraine and the Relation of Allergy," and Edward J. Curran, "Migraine from the Standpoint of the Ophthalmologist."—Dr Albert M. Snell, Rochester, Minn., addressed the Kansas City Academy of Medicine, October 20, on "Differential Diagnosis of Conditions Associated with Jaundice."—Dr Louis L. Williams, Jr., of the U. S. Public Health Service discussed the "Possible Relation of Insects to Encephalitis" at a meeting of the Academy of Science of St. Louis, October 11.—The Kansas City Tuberculosis Society observed its twenty-fifth anniversary, October 4. Dr Stuart Pritchard, Battle Creek, president of the National Tuberculosis Association, was the guest speaker on "Newer Trends in the Tuberculosis Field."

MONTANA

Society News—The Montana Academy of Ophthalmology and Otolaryngology was addressed recently at Anaconda by Drs Howard C. Naffziger, San Francisco, and George W. Swift, Seattle on neuro otology and neuro ophthalmology, respectively.

NEBRASKA

Omaha Clinical Assembly—The Omaha Mid-West Clinical Society will hold its first annual assembly, October 30-November 3 at the Paxton Hotel, Omaha. Mornings will be given over to general assemblies and afternoons to clinics, with three evening meetings and daily luncheons at all of which guest speakers will be present. Following are the guests, with their subjects:

Dr Joseph C. Birdsall Philadelphia Diagnosis and Treatment of Renal Infections. Diagnosis and Treatment of Urinary Calculi.
Dr James T. Case Chicago Normal and Pathologic Motor Physiology of the Colon. Diagnosis of Chronic Obstruction of the Small Intestine.
Dr Wells P. Eagleton Newark N. J. Infection of the Petrous Apex and the Sphenoidal Base and Its Relation to Streptococci and Pneumococci Meningitis. Immediate Past and Immediate Future of the Practice of Medicine in a Large Eastern City.
Dr Hugo Ehrenfest St. Louis Birth Injuries of the Child. Pregnancy Complicated by Extraneous Disease.
Dr James B. Herrick Chicago Clinical Recognition of Coronary Thrombosis. Individualization in the Practice of Medicine.
Dr Julius H. Hess Chicago Present Status of Serum Therapy in Pediatrics.
Dr Richard H. Jaffe Chicago Leukemia. Sudden Death from Natural Causes.
Dr Dean Lewis Baltimore President American Medical Association. Soft Part Injuries Occurring in Fractures. Surgical Problems.
Dr Lewis John Pollock Chicago Neurology and General Medicine. Some Neck and Labyrinthine Reflexes.
Dr Edward H. Skinner Kansas City And the Doctor Is Still with Us.
Dr Allogg Speed Chicago Knee Joint Injury. Exclusive of Fractures of the Neck of the Femur.
Dr Frederick D. Weidman Philadelphia Commonly Misunderstood Features About Cutaneous Cancer. Dermatomyoma Is Down to Date.

In addition there will be intensive lecture courses by Omaha physicians each day from 11 to 1 o'clock until Friday, when the entire session will be devoted to clinics in St Joseph's, University of Nebraska and Omaha-Douglas County hospitals. Scientific exhibits will also be part of the program, including a fresh pathology exhibit furnished by the departments of pathology of the University of Nebraska and Creighton University schools of medicine.

NEVADA

State Medical Election—Dr Edward E Hamer, Carson City, was chosen president-elect and Dr David A Smith, Mina, was installed as president of the Nevada State Medical Association at the annual meeting at Las Vegas in September. Drs Julius N Van Meter, Las Vegas, and Walter H Frolich, East Ely were elected vice presidents and Dr Horace J Brown, Reno, secretary. The next annual meeting will be held in Reno.

NEW YORK

Society News—Dr Burton T Simpson Buffalo, addressed the Broome County Medical Society, Binghamton, October 3, on "Responsibility of the Practicing Physician in the Control of Cancer"—Dr Howard M Clute Boston addressed the Medical Society of the County of Montgomery Amsterdam October 4 on carcinoma of the colon and rectum—Drs George M Gelser and George W O Grady, Rochester, addressed the Ontario County Medical Society recently on "Trichomonas Vaginalis Vaginitis".

Lectures on Physical Therapy—Dr Richard Kovacs New York, is presenting a series of lectures on physical therapy before the Medical Society of the County of Niagara at Niagara Falls, under the auspices of the committee on public health and medical education of the Medical Society of the State of New York. The first two were on "Heat Measures Following Diathermy" and "Low Frequency Currents Electrodiagnosis, Massage and Exercise," given October 17 and 24, respectively. The third will be on "Ultraviolet Radiation Therapy in Medical Conditions," October 31, and the last, "Physical Therapy in Surgical, Gynecological and Other Conditions," November 7.

A Village for Delinquent Boys—A state training school for delinquent boys with a medical unit for the study of their behavior was dedicated at Warwick, October 15. The \$2,000,000 building project now includes thirty-two finished buildings, with two more still to be constructed. The school is a self contained village where the boys will receive regular school work and vocational training. The Columbia University Medical Center is cooperating in a medical psychiatric study to determine methods of rehabilitating these boys for society. Dr Frederick Tilney, professor of neurology and neurologic anatomy, is chairman of the medical board which has been conducting clinics for the children for the past year. About 300 boys are already settled at the school. Its capacity is 500. Teachers College of Columbia University is collaborating in the educational program and the state is now seeking advice of business men concerning the occupational future of the boys, according to Dr Tilney in his address at the dedication. There will be a resident staff and a visiting staff which will include specialists in various branches of medicine, dentists, surgeons, psychologists and social workers. Acute medical and surgical emergencies will be cared for at the school hospital or at the medical center in New York.

New York City

Hospital News—The Society of Eye-House Surgeons of the Manhattan Eye, Ear and Throat Hospital held a two day reunion September 22-23. The program included clinics and demonstrations at the hospital and a dinner at the New York Physicians Club. Dr Walter Guernsey Frey, Jr, is secretary of the organization.

United Hospital Fund Report—The fifty-six hospitals comprising the United Hospital Fund of New York spent \$25,132,175 in 1932 and received from patients \$17,508,920 according to the annual report made public, October 17. The report stresses the economies made by the hospitals during the financial emergency. Continuous studies are being carried on of methods of reducing maintenance expenses. Henry J Fisher is president of the fund and Homer Wickenden, general director.

Society News—Drs Frederick S Wetherell Syracuse, and Gabriel Tucker, Philadelphia, addressed the Medical Society

of the County of Kings, October 17, on "Relief of Pelvic Pain by Sympathetic Neurectomy" and "Bronchoscopic Observations of Postoperative Pulmonary Complications," respectively—Dr Edward H Dennen gave an afternoon lecture before the Medical Society of the County of Queens, October 20, on "The Application of Forceps"—Dr Laurence David Redway addressed the October meeting of the American Stomatological Association, October 25, on "Color-Recording of Clinical Pathology with Special Reference to the Eye".

Visit of Brazilian Physicians—Seventeen Brazilian physicians recently visited New York under the auspices of their government to study medical institutions of the United States. A program was presented in their honor at the New York Polyclinic Medical School and Hospital, September 27, comprising surgical demonstrations, inspection of the hospital and a luncheon. The New York chapter of the Pan-American Medical Association also gave a reception at Rockefeller Center, September 26, at which speakers included Sebastian Sampaio, consul general of Brazil in New York, Enrique Ruiz, consul general of Mexico, and Dr Willard C Rappleye dean, Columbia University College of Physicians and Surgeons.

NORTH CAROLINA

District Meeting—The Ninth District Medical Society held its annual meeting in Mooresville, September 27, with the following scientific program: Drs Clarence C Craft, Hickory, "Blood Chemistry"; George W Taylor, Mooresville, "Endo crines in Gynecological Problems"; Angus M McBryde Durham, "Epilepsy and Convulsions"; Oscar L Miller, Charlotte, "Fractures of the Forearm," and David T Smith, Durham, "Vincent's Infection of the Mouth and Lungs." After dinner speakers were Drs Isaac H Manning, Chapel Hill, president, Medical Society of North Carolina, Wingate M Johnson, Winston-Salem, John Q Myers, Charlotte, and Frank Howard Richardson, Black Mountain and Brooklyn, N Y.

OKLAHOMA

New Secretary of State Society—Dr Leonard S Wilbur, McAlester, has been named secretary-treasurer of the Oklahoma State Medical Association and editor of its official journal to succeed the late Dr Claude A Thompson, Muskogee.

Fall Clinical Conference—The fourth annual fall clinical conference sponsored by the Oklahoma City Clinical Society will be held, October 30-November 2. Sixteen guest lecturers will attend to give instruction at general assemblies, luncheon and dinner meetings. In addition, more than 100 hours of graduate lectures will be given by Oklahoma physicians. The guests will include:

Dr Dean Lewis Baltimore President American Medical Association
Bone Lesions and Differential Diagnosis Tumors of the Breast
Dr Harlow Brooks New York Angina Pectoris Rheumatic Fever Rheumatism
Dr Morris Fishbein Chicago editor THE JOURNAL Changes in the Nature of Medical Practice
Dr Alfred I Folsom Dallas Texas Prostatic Resection Chronic Bladder Irritation in Women
Dr Irving F Stein Chicago Practical Consideration of Sterility Oxyperitoneum in the Diagnosis and Treatment of Tuberculous Salpingitis
Dr Alan G Brown Toronto Bronchiectasis Common Errors in Diagnosis and Treatment of Disorders of Childhood
Dr Elliott P Joslin Boston Diabetes Mellitus and Its Complications
Dr Everts A Graham St Louis Diagnosis and Treatment of Carcinoma of the Lung Surgical Treatment of Bronchiectasis Hypoglycemia as a Surgical Problem

Two symposiums will be presented Monday and Wednesday evenings, one on the abdomen by Drs Byrl R Kirklin, Rochester, Minn, Isidore Cohn, New Orleans, and Dean Lewis, the other on medical subjects by Drs George E Fahr, Minneapolis, Alan G Brown and Elliott P Joslin. The annual clinic dinner will be given Tuesday evening in honor of all the guests, with Dr Fishbein as the principal speaker.

PENNSYLVANIA

Society News—Drs Esten L Hazlett Canonsburg, and David N Ingram, Houston addressed the Washington County Medical Society Washington October 11, on industrial medicine—Dr William L Estes, Jr Bethlehem, was elected president of the Lehigh Valley Medical Society at the annual summer session in August—Dr Richard P Custer, Philadelphia, addressed the Cambria County Medical Society, October 12, Johnstown, on "The Reticulo-Endothelial System and Some of Its Diseases"—Dr Gabriel Tucker, Philadelphia discussed bronchoscopic examinations as guest speaker of the Harrisburg Academy of Medicine October 17. Dr Benjamin

M Baker, Jr., Baltimore, spoke on angina pectoris, September 19—Dr Jesse L Lenker addressed the Dauphin County Medical Society, Harrisburg, October 10, on pernicious anemia

Philadelphia

Cancer Meeting—The Philadelphia Commission on Cancer will hold an all-day meeting on cancer at the American Oncologic Hospital, November 15. A general meeting will be held in the morning, followed by a clinical conference and separate meetings of the radiologic and surgical and the pathologic divisions. Among other speakers will be Drs William S Newcomet, on 'Five and Ten-Year Results of Treatment of Neri and Hemangiomas', Frederick A Bothe, "Tumors of the Kidney" and Stephen E Tracy, "Technic of Filtration and Intravaginal and Uterine Irradiation"

VIRGINIA

Society News—Among speakers at a recent meeting of the Southwestern Virginia Medical Society at Wytheville were Drs William W S Butler and C H Peterson, Roanoke, on 'Recent Developments in Prostatic Resection', Leland E Starr, DVM Blacksburg, "Undulant Fever in Man," and Dr Elbyrne G Gill, Roanoke, "Bronchoscopy Its Value to the General Practitioner"—Dr Maxwell E Lapham, Philadelphia, began the seventh circuit of the graduate course in prenatal and postnatal care sponsored by a joint committee of the Medical Society of Virginia, Medical College of Virginia and the University of Virginia. Centers in which this ten weeks' course will be given are Martinsville, Chatham, Danville, South Boston and Boydton

WASHINGTON

Society News—Dr John Ruhrh, Baltimore, addressed the King County Medical Society, Seattle, September 20, on poliomyelitis. Dr Alson R Kilgore, San Francisco, was the speaker, October 16, on "Cancer and Precancerous Conditions of the Breast"—Dr James Marr Bisailon, Portland, Ore, addressed the Walla Walla Valley Medical Society, October 12 on 'Differential Diagnosis of Postoperative Lung Complications'—Drs Albert P Duryee and Herbert W E Johnson addressed the Snohomish County Medical Society, Everett, September 6 on 'General Aspects of Cancer' and 'Malignancies of the Genito Urinary Tract,' respectively

WEST VIRGINIA

Society News—Drs Arthur A Shawkey, Charleston, and Randolph L Anderson, Richmond Va, addressed the Logan County Medical Society, Logan, September 20, on 'The Hyper-tonic Infant' and 'Injuries About the Wrist Joint,' respectively—Drs Thomas R Boggs, Baltimore, and J Ross Hunter, Charleston, addressed a joint meeting of the medical societies of Harrison Marion and Monongalia counties at Clarkburg, on 'Disturbances of the Heart Rhythm from the Standpoint of the General Practitioner' and 'Radium Therapy in Cancer of the Uterus and Breast' respectively—A symposium on pediatric subjects was presented before the Cabell County Medical Society, Huntington, September 14, by Drs William Byrd Hunter, who spoke on immunization. Raymond M Sloan care of the mentally handicapped, Will D Hereford nursing service and George M Lyon, infant mortality

GENERAL

Dr Rosenau Awarded Sedgwick Medal—Dr Milton J Rosenau, Charles Wilder professor of preventive medicine and hygiene, Harvard University Medical School, Boston, was presented with the William T Sedgwick Memorial Medal by the American Public Health Association for distinguished service in public health. The first award of the medal was made in 1929 when it was given to Dr Charles V Chapin, Providence, R I. The medal was established in honor of William T Sedgwick, PhD, a former president of the association (THE JOURNAL, July 13, 1929, p 127)

Automobile Fatalities in Four Weeks—The bureau of the census, U S Department of Commerce, announced that eighty six large cities in the United States reported 706 deaths from automobile accidents for the four weeks ended September 30 as compared with 651 deaths for the four weeks ended Oct 1, 1932. Most of these deaths were the result of accidents which occurred within the corporate limits of cities although some accidents occurred outside of the city limits. For the fifty two week periods ended Sept 30, 1933 and Oct 1, 1932 the totals for all the cities were 8,093 and 8,273 respectively which indicate a recent rate of 21.4 per hundred thousand population

Thomas Hunt Morgan Wins Nobel Prize—Thomas Hunt Morgan, PhD, director, William C Kerckhoff Laboratories of Biological Sciences, California Institute of Technology, since 1928, has been awarded the Nobel Prize in medicine for 1933, in recognition of his "discoveries concerning the eugenic functions of chromosomes." Born in Lexington, Ky, in 1866, Dr Morgan graduated from the State College of Kentucky in 1888 and received his doctor's degree at Johns Hopkins University, Baltimore, in 1890. He was professor of biology at Bryn Mawr College, Bryn Mawr, Pa, from 1891 to 1904 and from then until 1928, professor of experimental zoology at Columbia University, New York. Dr Morgan was president of the National Academy of Sciences from 1927 to 1931 and his literary contributions include 'The Development of the Frog's Egg', 'Regeneration', 'Evolution and Adaptation', 'Experimental Zoology', 'Heredity and Sex', 'Mechanism of Mendelian Heredity', 'Critique of the Theory of Evolution', 'The Physical Bases of Heredity', and 'The Theory of the Gene'. He has written numerous monographs and papers on biologic and embryologic subjects

Society News—Dr Frederick S Baldi, Philadelphia, was elected president of the Medical Section of the American Prison Association at the annual meeting in Atlantic City, October 8-13. Dr Edith A MacLeod, Natick, Conn, was elected vice president and Dr James L McCartney, Elmira, N Y, reelected secretary—Dr Robert B Greenough, Boston, was named president-elect of the American College of Surgeons at the annual congress in Chicago, October 12. Dr William D Haggard, Nashville, Tenn, was installed as president and Drs Charles A Dukes, Berkeley, Calif and Roscoe R Graham, Toronto, Ont, were elected vice presidents—The National Conference on Rehabilitation of Disabled Persons was held in Chicago, October 8-13. Physicians who addressed the meeting include Drs Earl R Carlson, New York, on "Physical Restoration of the Spastic", Fred H Albee, "Bone Car-pentry", Henry H Kessler, Newark, N J, 'The Kinetic Stump and Appropriate Prosthesis', and Frederick Tice, Chicago, 'The Physician's Viewpoint on Rehabilitation'. Dr Morris Fishbein, Chicago, editor of THE JOURNAL, gave an address at the annual banquet on 'The Doctor in the Program of Rehabilitation'.—Maj-Gen Harry L Gilchrist was elected president of the Association of Military Surgeons of the United States at the annual meeting in Chicago in September, succeeding Dr Ralph C Williams of the U S Public Health Service

Government Services

Dr Marlatt Retires

Charles L Marlatt, Sc D, chief of the Bureau of Entomology, U S Department of Agriculture since 1927, retired October 1, having reached the age of 70, September 26. Dr Marlatt became associated with the department in 1889 and was assistant chief of the bureau of entomology from 1894 till his appointment as chief. He organized the Bureau of Plant Quarantine in 1927 and served as its director until December, 1929. Mr Lee A Strong, who was appointed chief of the new bureau at that time, now succeeds Dr Marlatt as chief of the Bureau of Entomology

Hospital Positions Available

The United States Civil Service Commission announces an examination for the position of junior medical officer (intern) to fill vacancies at St Elizabeth's Hospital and other positions requiring similar qualifications. The salary will be \$2,000 a year less a deduction of not more than 15 per cent as an economy measure and a retirement deduction of 35 per cent. A further deduction of \$60 a year will be made for quarters. Competitors will not be required to report for an examination but will be rated on their education and experience. Full information may be obtained from the secretary of the U S Civil Service Board of Examiners at the postoffice or customhouse in any city or from the commission at Washington, D C. Applications must be filed before November 15.

CORRECTION

Magnification in Photomicrographs—In the article by Dr A P Vastola, THE JOURNAL, July 8, 1933, page 113, appear two photomicrographs. Figure 5 is labeled as having been magnified 125 times whereas the magnification is actually 25 times.

Aid for Refugee Scientists

Professor Einstein was the principal speaker at a meeting in London in the Albert Hall to raise funds for the Refugee Assistance Committee. More than 8,000 persons paid for admission and nearly \$500,000 was obtained. The physicist Lord Rutherford presided. He said that four bodies were concerned in relief work for academic and professional workers: the Academic Assistance Council, of which he is president, the International Students Service, the Refugee Professionals Committee, and the German Emergency Committee of the Society of Friends (Quakers). Their object was to collect a fund for the relief of students, university teachers and members of the professional classes. They were working on behalf of all men of science and learning of all countries who had been debarred through no fault of their own from carrying on their specialized work. There was a flood of refugees into other European countries, which were generously giving what help they could. Comparatively few had reached England but the Academic Assistance Council had the names of more than 1,000 teachers of all grades who had lost their posts. Our contribution could not be to provide a refuge for a large number on British territory. It must mainly be financial, combined with temporary refuge at universities and learned institutions for scholars and scientists faced with destitution. Among these are men renowned in every branch of science. The point must be emphasized that there are quite as many Gentiles as Jews. This brings out the point, that, while the Jews as a race are persecuted, the motive of the persecution is political. It is directed against all persons of pacifist or liberal views. Thus the physicist Schroedinger, whom Oxford has been fortunate to secure, is not a Jew. Physicists and chemists predominate among those seeking employment, and it is hoped that the two Nobel prize winners Prof. James Franck of Goettingen and Professor Haber of Berlin, who invented the synthetic process of producing ammonia from the atmosphere will soon find laboratories in this country for further research. So far, 200 of the 1,000 expelled university teachers have been accommodated. Among the countries that have been able to obtain their services are the United States, France, Russia and Spain. Ireland, China and Venezuela, poor as are their resources have offered to provide a home for a few. Negotiations on the subject are pending with the Turkish government. Dr. Hermann Zondek, formerly professor of internal medicine, Dr. Bernhard Zondek, formerly professor of gynecology and obstetrics, and Dr. Samuel G. Zondek, formerly professor of pharmacology at Berlin, have been appointed, respectively, consulting physician, consulting gynecologist and consulting bacteriologist to the Manchester Victoria Memorial Jewish Hospital. The second is known the world over for his hormone test for pregnancy.

Professor Einstein, who spoke in English, expressed his deep sense of gratitude as a man, as a good European and as a Jew. Through its well organized work of relief, the Assistance Committee had done a great service not only to innocent scholars who had been persecuted but also to humanity and to science. It had shown that the British had remained faithful to the traditions of tolerance and justice which for centuries they had upheld with pride. Let them hope that when a historian delivering judgment at some future period when Europe was politically and economically united, would be able to say that in their days the liberty and honor of this continent were saved by its Western nations.

Other distinguished persons, including the bishop of Exeter, Sir James Jeans, Lord Buckmaster, judge of the supreme court, Dr. Maude Royden, the preacher, and Sir Austen Chamberlain, also spoke. Sir Austen said that he was there to make an act of faith and profession of sympathy with people who were suffering for causes which they had hoped had ceased to operate among civilized nations. He could imagine no greater tragedy that could smite learning and art and science than the proscription in the twentieth century of a whole people who had distinguished themselves in the arts and science in every country and through all ages.

The Anti-Noise League

Though formed only a little over a week ago, the success of the Anti-Noise League exceeds expectations. The league has been inundated with hundreds of applications for membership, many of them from prominent persons, such as the chairman of the London county council, members of parliament, magistrates, lawyers, university dons, and professional, literary and business men. Though automobile noises are a great subject of complaint there appears to be no conflict of opinion between the league and motorists generally as to the need to find a remedy. It is only the exceptions among drivers who are offenders. Railway whistles, phonographs, loud speakers, barking dogs, milk cans, rock drills and itinerant musicians also are a nuisance. Lord Buckmaster, who is a member of the committee, intends to move a resolution dealing with the whole subject on the reassembling of the house of lords.

Retirement of Sharpey-Schafer

The veteran physiologist Sir Edward Albert Sharpey-Schafer has retired from the chair of physiology at Edinburgh at the age of 83. His past and present assistants, numbering twenty-nine, have published in his honor a special volume of the *Journal of Experimental Physiology*, consisting of original researches carried out by themselves. There are thirty-two papers, which cover a wide field of interest, and their final editing was placed in Sir Edward's hands. His classic contributions to physiology are daily used by research workers all over the world. To the profession at large and to the public he is best known for his method of artificial respiration, which constituted a great advance on previous methods.

Martyrs to the X-Rays

The list of radiologists in this country who have suffered serious injury, which often proved fatal, because the dangers were not at first appreciated and safeguards were not adopted, is long. One of the most eminent was Dr. Robert Knott, director of the electrical and radiotherapeutic department of the Cancer Hospital, London, editor of the *British Journal of Radiology* and well known as an author of books on radiology. He succumbed to his injuries in 1928. Other victims were Dr. A. Parsons of the Seamen's Hospital, Greenwich, R. G. Blackhall of the London Hospital who lost both his hands, Dr. A. C. Taylor of Peterborough, Dr. J. Hall Edwards of Birmingham whose hands and arms were amputated as the disease spread, Dr. J. Redfern of Manchester, Sir A. D. Reid of St. Thomas's Hospital, T. Dodd one of the pioneers of the use of the X-rays in Newcastle, Alfred Smith, radiographer of the Coventry Hospital who underwent seventeen operations in four and one-half years and died last January, and Dr. Stanley Melville radiologist to St. George's Hospital, who has lost a finger and is in danger of losing more. The latest victim is Dr. W. Hope Fowler consulting radiologist to the Edinburgh Royal Infirmary. From 1901 to 1911 he was assistant medical electrician and from 1911 to 1926 radiologist. Throughout the war he was honorary consulting radiologist to the admiralty and member of the war office X-ray commission. He was a well known writer on his speciality and attended the

last meeting of the British Medical Association after undergoing an operation. He had two fingers of his right hand amputated at different times and last June his right hand. The king conferred on him the commandership of the Royal Victorian Order and warmly praised him for his self-sacrificing labors. He has just succumbed at the age of 57.

The Early Diagnosis of Cancer The Danger of Consulting Quacks

At the opening of a new cancer hospital in Liverpool, Lord Moynehan delivered an address in which he summed up the present position. Much was still being learned regarding the role and the range of radium as a curative agent. But the chief improvement in the control of cancer would come from earlier diagnosis. This would not be possible until physicians and patients learned to recognize the earliest departure from health which gave warning of the advent of cancer. Lord Moynehan spoke earnestly against the credulity of the public and its belief in quacks, who had never yet cured a case. He urged all persons to consult their physicians about doubtful lumps, ulcers or unusual symptoms. He emphasized that cancer attacked a diseased rather than a healthy organ and that there were precancerous conditions that should not be neglected. He did not believe in hereditary predisposition to cancer.

PARIS

Sept 13 1933

Results from Use of Electroprexia in France

Apparatus for the application of electroprexia was brought to Paris from America, two years ago, by Mr Philippe de Rothschild, son of Baron Henri de Rothschild, the philanthropist, who presented one to each of three hospitals: his private hospital, the Hopital de la Salpetriere and the Hopital des Aveugles. Dr Auclair, hospital physician, has published a report of his results with this method, in which he employed sometimes diathermic heat and sometimes short wave heat up to 40 and 41 C. The report is long, including a large number of different diseases. The most important was dementia paralytica. The results were essentially the same as those secured by Carpenter and Neyman in America. The improvements concerned chiefly the mental state, without much change in the serum reactions, except when antisyphilitic treatment was given at the same time. Of nineteen patients three were able to resume their previous occupations without any supervision, four showed sufficient improvement to be allowed to live at home under moderate supervision. In combination with antisyphilitic treatment the results show an advantage over malaria therapy, but one does not observe the rapid changes in the serum reactions secured with malaria therapy. Mr Auclair prefers electroprexia to malaria therapy in the treatment of dementia paralytica. He employed the method also in six cases of tabes, securing a slight improvement in two cases and in all cases an arrest of the evolution of the disease after from twenty to twenty-three sittings. The results were much more encouraging in beginning tabes. In one patient who had gastric crises and optic atrophy with progressive diminution of vision the unstable gait and the gastric crises disappeared and the blindness retrograded appreciably. In one patient the Wassermann test which had been negative for years became rapidly positive. In eight cases of Parkinson's disease, six of which were postencephalitic electroprexia produced improvement, influencing particularly contracture and somnolence but affecting the tremors only to a slight extent. It permitted the patients to resume their occupations and allowed them to omit the medical treatment to which they were accustomed. Of three cases of non-syphilitic myelitis there was an appreciable improvement in two with diminution of the painful contractures

and of the subjective disturbances of sensitivity. In one case there was almost complete disappearance of sphincteral disorders. Two cases of syphilitic myelitis were successfully treated, but antisyphilitic treatment was administered simultaneously. Two cases of multiple sclerosis completely failed to improve in spite of twenty-three separate treatments. Twelve cases of poliomyelitis gave remarkable results, often rapidly. A girl, aged 10 years, affected for eighteen months with paraplegia with total degeneration reaction, in whom the damage appeared permanent in spite of many treatments with radiotherapy, diathermy and galvanotherapy was able at the end of two months, after twenty-four treatments with electroprexia to the exclusion of all other treatment, to walk with but slight use of crutches.

Dr Auclair undertook experiments on diseases other than those of the cerebrospinal axis. He secured remarkable results in obesity. The losses of weight varied from a few hundred grams to 2 Kg in two hours, with rapid later recovery, provided due attention was given to the diet. It is easy to bring about a loss of 600 Gm at each sitting in a person of average obesity for a period of ten sittings. The greatest success was obtained in treating patients with rheumatism: eighty such patients received treatment. The treatment was applied preferably during intervals between acute attacks in algias of the most diverse types, alkylating arthritis, various forms of monoarthritis, and even arthritis of the hip, polyarthritis and infectious monoarthritis. In nearly all cases he brought about a reduction of pain, an improvement of function and sometimes improvement in the anatomic lesions. There were only seven complete failures, three of which were in patients with low blood pressure, in whom the treatment could not be applied above 38.05 C in the presence of signs of oppression, while two were in persons with a subacute evolution of the disease. He secured good results in the treatment of gout, sciatica and neuritis, even when associated with vertebral arthritis, and particularly in neuralgia, torticollis and lumbago. In persons with high blood pressure a lowering of the arterial tension was brought about, a reduction that could be maintained for months, with great improvement in the general condition. In five cases of arthritis of the lower limbs an improvement was effected, and in one case at the end of a year an almost complete recovery. Auclair mentions also good results secured in the treatment of rebellious migraine, generalized eczema, essential asthma, cirrhosis salpingitis and abdominal adhesions. On the contrary complete failure was observed in all manifestations of gonorrhea. When applied in two acute cases of urethritis, orchitis developed immediately in each case. The field of application of electroprexia appears to be rather limited.

The Wine Producers of France

The wine producers of France are making efforts to combat the economic crisis and are resorting to many forms of propaganda. They have established many grape supply stations in order to increase the consumption of fresh grapes and, following the example of Italy, have set apart a special week for the promotion of fruits of the vineyard. In the large waiting room at the St Lazare railway station in Paris they have set up a bar where travelers may secure not only fine grapes but also fresh grape juice pressed out in their presence. Furthermore they have called the medical profession to their aid, and in order to bring before the public the merits that they accord to wine they organized a convention of physicians who are advocates of French wines. This convention was held September 8 and naturally at Bordeaux, the center of the wine industry. A considerable number of physicians, chiefly natives of the region among others professors at the faculties of medicine attended the convention and sang the praises of wine.

In reality the economic crisis affecting the wine producers is due chiefly to the fact that France produces, along with

Algeria and Tunisia, much more wine than is needed in a country where considerable quantities of beer and cider are used. Then there is the fact that the export trade has diminished since other countries are struggling with an overproduction. The overproduction concerns chiefly mediocre wines. As for the well known brands emanating from Bordeaux, Bourgoyne and Champagne, they have to meet sharp competition in foreign countries. No convention will succeed in getting the French people to drink more wine than they drink already. The government has, in its weakness, permitted all unsold wine to be transformed into alcohol and has agreed to purchase all alcohol so produced. The government has today such large stocks of alcohol on hand that it is compelling the owners of filling stations to mix alcohol with motor fuel in the proportion of 10, 15 and even 20 per cent. The owners of automobiles are complaining bitterly that this defective fuel cuts down their mileage and damages their carburetors. But southern France, whence come the floods of wine, has always had great political influence in parliament. Thus the question of wine has become one of the embarrassing problems of the French government.

Temporary Regulations for Animal Experimentation

A recent letter (*THE JOURNAL*, September 30, p. 1087) announced the new strict regulations pertaining to vivisection. The possibilities of scientific animal experimentation were left for future elucidation. Goring, chairman of the Prussian cabinet on the basis of the conferences between representatives of science and those of the societies for the prevention of cruelty to animals, has now issued interpretations that will remain in effect until a federal law for the protection of animals is promulgated.

"Vivisection" is defined as dissection of an unanesthetized living animal or an operation in which, in the same interventions on man, anesthesia is usually employed. Bloodless animal experiments on unanesthetized animals, which constitute maltreatment, are to be considered as identical with vivisection.

Since serious scientific research, in the interest of the health and life of men and animals, cannot dispense with animal experimentation, it will not be regarded as vivisection if the following conditions have been observed:

Scientific animal experiments may be carried out only in institutes under scientific management, and only on the responsibility of the director of the institute.

Animal experiments may be undertaken only when scientific considerations promise a definite result. They must not be resorted to if, in the field of science concerned, the question at issue has already been clarified.

Scientific experiments are to be carried out in a painless manner, through the use of general or local anesthesia, provided in the opinion of the director, the purpose of the experiment does not exclude anesthetization or the pain involved is less than the discomfort that anesthetization would cause.

In principle, experiments on the higher animals should be avoided. If, however, the purpose of the experiment cannot be satisfied by the use of lower animals, experiments may be carried out also with higher animals. No more animals may be used for the experiment than are necessary for the elucidation of the question involved. Scientific institutes that do not hold a concession under the state, the commune or the municipality must secure ministerial approbation of contemplated animal experiments. Animal experiments for purposes of instruction are permissible only when other methods such as pictures, films, preparations and models do not suffice. These experiments also require the consent of the central authorities having jurisdiction.

Head Professors and Private Practice

In a recent letter it was announced that the Prussian minister of public instruction is planning a reorganization of the system of higher learning, and that it is not impossible that certain rights heretofore guaranteed by contract may be invaded (*THE JOURNAL*, July 3, page 535). The federal minister of the interior and the federal minister of finance have now issued regulations which provide that every form of auxiliary employment for which an emolument is accepted shall be subject to the securing of definite permission. Medical, veterinary and dental officers, including the instructors in public institutions of higher learning are subject to the same regulations as other officers. So far as the situation can be determined at present the head professor in a clinic would not, as formerly, be allowed to attend to a private practice, nor would other physicians holding official posts be able to pursue their previous outside employments. A definitive settlement of the whole question has not been reached and until definite federal regulations have been formulated the supreme federal or state authorities may permit private practice. It is, however, expressly stated that such officers may not participate in *Krankenkassen* practice. Such officers will be asked to serve as arbitrators or medico-legal experts only when public interest demands it or other suitable persons are not available. It is further recognized that any industrial or occupational work on the part of the wife of such an officer must be made known to the proper authorities.

Reorganization of Institutions of Higher Learning

The Baden minister of public instruction who has jurisdiction over the universities of Freiburg and Heidelberg and the polytechnicum in Karlsruhe, has issued an order that provides for complete reorganization of institutions of higher learning in Baden and that will doubtless blaze the way for extensive reforms throughout the reich. According to the order, the rector will be vested with all the prerogatives of the previous senate (the full assembly and the senate council). The rector will no longer be chosen by the members of the faculty but will be appointed by the minister of public instruction (from among the number of head professors) and will be bound by an oath. The rector has the right to appoint, from the faculty body, a chancellor to represent him. The post of rector as established by this decree will date from Oct. 1, 1933. His tenure of office (previously one year) will be determined by the ministry. The tenure of office of the deans and the senators will be determined by the rector. He has the authority to dismiss them at any time, although the right of appeal to the ministry is reserved to the persons so affected.

Centers for the Care and Prevention of Tuberculosis

In 1931, approximately seven tenths of the persons who died from tuberculosis were previously known to the special centers for the care and prevention of the disease. Of the total number of deaths, about four tenths occurred in hospitals and six tenths in the homes of the patients. In nearly one fifth of the deaths in the homes, the hygienic conditions of the dwellings were not free from objections. The social movement for the care and the prevention of tuberculosis had 896 principal centers and 696 auxiliary centers. The work was carried to about 85 per cent of the communes. Performing service in these centers were 253 full-time, 1,051 part-time and forty-three voluntary physicians, 373 female special social workers, 2,493 female general social workers and 628 other persons. The centers had 320 pieces of roentgen apparatus at their disposal. After admitting 285,403 and dismissing 267,261 persons the total number being cared for at the end of the year 1931 was 611,317. Of the new admissions 26.6 per cent were referred by physicians, 18.0 per cent by boards and by insurance agencies, 34.1 per cent were summoned by the centers as being endangered.

by their environment, while 23.1 per cent reported of their own free will. For the domiciliary care of patients, the centers had available 1,475 communal nurses and 9,890 nurses connected with private social work.

Various Types of Pneumonia

Professor Morawitz, clinician, of Leipzig described recently the clinical aspects of the various types of pneumonia, on the basis of a study of ninety cases of croupous pneumonia occurring last winter. The peak of lobar pneumonia coincided with the influenza epidemic in January. The total mortality was 30 per cent. Arranged according to types, the records showed: type I, 40 per cent of the cases, mortality 15 per cent; type II, 32 per cent of the cases, mortality 30 per cent; type III, 15.8 per cent of the cases, mortality 55 per cent; so called type IV, remainder of the cases, no deaths. The prognosis varies for the several types. Serum therapy also offers better prospects in types I and II. It is effective only during the first seventy-two hours. Type specific serums give the best results. Determination of the type of pneumococcus is possible within six to eight hours. The mortality of the cases in which serum was employed was from 20 to 40 per cent less than that of the cases in which no serum was used. In all cases, quinine therapy was used in addition. A favorable effect was produced also by the intramuscular injection of calcium salts. Morawitz stated that it was only a matter of time and the preparation of highly active serums before serum therapy would be universally accepted. Observations show that polyvalent serums are less effective. Intravenous injections of serum were not used.

Environment and Crime

The Prussian Association of Medical Officers held recently in Bad Pyrmont its fiftieth annual session. Special attention was centered on two papers on the combating of crime from the points of view of demographic science, hereditary biology and race hygiene, as presented by Dr. Schuett of Wuppertal and Dr. Viernstein of Munich, who believe that there has been a tendency, since the war, to exaggerate environment in influencing the conduct of criminals. They hold that the state must apply new deterrents, for example, public defamation, pillory, banishment, confiscation of property and the whipping post. By prophylactic measures and sterilization lawbreakers with inherited criminal tendencies must be prevented from handing on to posterity their hereditary inferiorities to the detriment of the common weal.

Examination and Adjustment of Medical Fees

Dr. Wagner, commissar of the medical leagues, recently announced that physicians are constantly being reproached for charging high fees for private services. Dr. Wagner emphasized that it is the duty of the physician to keep his fees within the established limits of the recognized fee schedule, in accordance with the nature and the difficulty of the performance, the financial position of the client and the local conditions. Owing to the low level of the economic status of many patients the minimal fees of the fee schedule should be applied often in private practice. In order to forestall these complaints whether justified or not the commissar has ordered that the directors whom he appoints shall examine and adjust the bills of private physicians which are sent to them at his direction by the medical society of the area in question. He reserves the right, on the basis of the expert opinions so rendered to take in every case whatever action seems best under the conditions. The closing sentence of the announcement reads: "In the interest of the medical profession as a whole the medical profession will assume the responsibility of eliminating the conditions within their ranks to which objection has been made, when it is found that there is justification for complaint and will thus avoid intervention by outside parties."

ITALY

(From Our Regular Correspondent)

Aug. 31, 1933

Studies on Biometry

A special study of biometry has been made by the Società fra i cultori delle scienze mediche e naturali of Cagliari, of which Prof. Luigi Castaldi, director of the Anatomic Institute of the University of Cagliari, is chairman. Brai presented a report on the indexes of variability and of correlation of human viscera in relation to external body measurements. From the abundant material collected at Florence by Castaldi and Vannucci, the speaker established that the index of variability is greatest for the spleen and the least for the liver. With regard to correlation, the variability was found to be greater for the liver, spleen and heart with relation to the anteroposterior and transverse diameters of the respective segments than with relation to the height measurements. The weight of the lungs alone showed greater correlation with the height than with the thoracic diameters.

Aromando, Coio-Pinna and Pintus presented an article on the relation between fertility and bodily constitution. They adopted the anthropometric method and used the statistics employed by Boldrini in his study on the fertility of fathers in the province of Padua. The investigators found, in studying the histories of 435 fathers of the province of Cagliari, that those who were short of stature had much fewer children, on the average, than the fathers who were tall.

Cao presented an article concerning the relations between occupation and fertility. He examined the histories of 435 fathers of the commune of Cagliari and divided them into two classes: bourgeoisie and manual laborers. The latter were divided into those doing heavy work and those doing light work. Among the bourgeoisie he found a larger number of tall persons, also among the manual laborers, although there were more short persons than among the bourgeoisie, the tall persons and the persons of middle stature predominated. There were more short persons among those doing heavy manual work than there were among those doing light manual work. With regard to the number of children, the average for the bourgeoisie was slightly under that for the manual laborers. Among the latter there were more tall children than children of short stature.

Lectures in Military Hospitals

In the series of lectures that the army medical corps has been organizing in the military hospitals, Professor Perussia, director of the radiologic institute of the University of Milan, spoke to the army physicians on the difficulties in the interpretation of roentgenograms in trauma of the bone. The radiographic diagnosis of a traumatic lesion may be difficult and may simulate a fracture that in reality does not exist. The speaker exhibited apparatus and described the devices that make possible to the trained radiologist a correct diagnosis in the majority of cases. Professor Perussia discussed the appearance of fractures as evidenced by callous formation, presence of supernumerary bones or of calcifications of the par-articular soft parts, congenital malformations and dystrophies.

In the military hospital of Turin Prof. Luigi Guglianetti, clinical ophthalmologist of the University of Turin, delivered a lecture on eye traumas emphasizing the vulnerability of the eye in modern war, owing to trench warfare. Guglianetti described certain cases of corneal wounds with coloboma iridis or with traumatic cataract and intrabulbar infection. He explained the uses of the giant electromagnet for the diagnosis of intrabulbar metallic foreign bodies and discussed the technical refinements and the indications for enucleation.

The diagnosis and treatment of syphilis constituted the subject of a lecture given by Prof Leonardo Martinotti at the military hospital of Bologna. He said that syphilis is, from the very onset, a septicemia, but at the onset researches on the blood have thus far proved negative. Susceptibility to contagion varies in different persons. The Wassermann test remains of primary importance. The flocculation reactions appear earlier but they are sometimes not specific. In secondary syphilis there may be forms of icterus that precede the appearance of the rash. There may be also acute yellow atrophy of the liver, often overlooked and nearly always fatal. Statistics, and particularly American statistics, show that at this period a high percentage of syphilitic patients have a positive reaction of the cerebrospinal fluid. In recent years, exanthems have been described resembling syphilitic exanthems. The speaker regards them as of an infectious nature and as possibly due to an influenzal virus. Treatment should begin as soon as the diagnosis is made. The best preparation of mercury in use today is mild mercurous chloride. The most potent spirocheticides are those with an arsphenamine base, introduced intravenously. In the late period of syphilis iodine should not be omitted. In neurosyphilis, malaria therapy gives excellent results, especially in dementia paralytica.

Appropriations for Improvements

The cabinet has approved an appropriation of 55,000,000 lire (\$4,400,000) for improvements in university and hospital centers at Padua, Florence and Pavia. The appropriation will cover enlargements and improvements in some of the more important buildings, particularly the clinics and the laboratories, in order that these university centers may be in a position to meet the growing needs of a constant increase in school attendance. The University of Rome has received a special appropriation of 300,000 lire (\$24,000) for the completion and equipment of the Clinica delle malattie tropicali e subtropicali. In Naples, new departments in the Ospedale dei Pellegrini have been established for the aid of mothers. At Perugia, 8,000,000 lire (\$640,000) has been appropriated for the reorganization of the polyclinic through the erection of a pediatric clinic, an otorhinolaryngologic clinic and a dermosyphilopathic clinic, various pathologic institutes and a library.

Sept 27 1933

The Selection of Medical Students

Prof B Boucek of Brno collected recently some interesting figures in Czechoslovakia on medical education which show a continuous increase in the number of medical students since 1926. The present number of medical students (over 6,000) was never reached before. He also traced the number of teachers and assistants at the medical schools and found that the teaching personnel had not increased correspondingly. This is more serious because the amount of teaching that must be presented to students is increasing rapidly. Professor Boucek followed further the progress of students during their stay at the medical school. He found that on the average there is one graduation a year among from seven to ten medical students. Only 15 per cent of the students pass the first examinations in the prescribed term. In his opinion, this is due to lack of care in selecting the students before they are admitted. In spite of this slow progress in their studies the number of those who graduate is far above the actual demands of medical practice. At the present rate of about 500 new graduates a year all possible openings for medical practice in Czechoslovakia will soon be filled, and a further increase in practitioners will lead to a lowering of the standard of living among physicians. It would be rational to estimate from time to time how many new medical

students should be admitted to the medical schools according to the actual demand of medical practice. The medical students should be divided among medical schools according to their teaching capacity. A special examination should be required before the admission of medical students, because a bachelor's degree, which is required, does not always qualify students for the study of medicine.

Insurance Societies and Public Hospitals

The present depression forces insurance societies to restrict their benefits to a minimum. The hospital benefit is an item of expenditure to insurance societies which is increasing constantly. The insurance authorities say the main cause is that public hospitals are inclined to prolong the stay in hospital for financial reasons. To obviate this the Central Insurance Institute has issued regulations which indicate how expenditures for hospital treatment can be kept by insurance societies within certain limits. Hospitalization, according to regulations, should not be ordered by the attending physician until it is approved by the chief physician of the insurance body. The regulations divide pathologic conditions subject to hospital treatment under sickness insurance into two groups: cases which require hospital treatment in all instances and those in which only special conditions in a given case make the hospital treatment desirable. Into the first group come all surgical cases and all acute cases endangering the life of the patient. The second group of cases comprises those in which local treatment facilities, bad housing conditions and suspicious circumstances about the origin of the disease make it advisable for the insurance society to entrust treatment to a hospital. Stress is laid on the fact that chronic diseases are not entitled to hospital treatment under the insurance benefit. The insurance bodies are invited to negotiate with the public hospitals for the purpose of making it possible that physicians of the insurance bodies may freely enter the hospital wards to control the physical condition of patients while in the hospitals.

Congress of Sanitary Engineering

A national congress of sanitary engineering and hygiene was held in Prague, September 1-5. The present time was not thought to be opportune for convening another international congress on the same topic, however delegates were present from Rumania, Bulgaria, Yugoslavia, France, Austria and Poland. There were among the participants many physicians, municipal administrators, contractors and manufacturers. The congress deliberated in three sections. The first dealt with city planning, in which chief interest was concentrated on the question of decentralization of cities and the provision of open spaces in large cities. The second section devoted most of its time to modern methods of construction of hospitals. The third section discussed the latest developments in water supplies and industrial hygiene. As a novel problem of sanitary engineering, the protection of cities against airplane attack was presented to members of the congress. Along with the regular program, several excursions were organized during which especially the progress in sanitary engineering of the city of Prague was shown to the visitors. The congress was held under the auspices of the minister of health of Czechoslovakia and of the mayor of Prague. At the same time an exhibit of sanitary engineering was held to show the new devices in this field placed on the market by various firms.

Death of Professor Biedl

Prof Arthur Biedl of the German faculty of medicine in Prague died recently. He is known in America through his research and also personally, for he lectured at the Johns Hopkins Medical School in 1923. He was born in 1869 of a German family in the south of former Hungary and came to Vienna to study medicine. After four years work in various

institutes of the faculty of medicine in this city he became lecturer on experimental pathology and in 1901 professor of the same subject in Vienna, where he lectured for thirteen years, on the death of Prof Ewald Hering, pathologist at the German faculty of medicine of Prague, he became his successor. Since then he had been connected with the Institute for Experimental Pathology of Prague. From the first, he took the stand that the teacher of experimental pathology must have free access to patients. Finally he succeeded in building up a clinic of medical propedeutics in connection with the Institute of Experimental Pathology. His scientific work deals almost exclusively with the problems of internal secretion, his textbook on the subject has been translated into many languages. He was among the first to investigate the pancreatic hormone. He showed clearly that the pancreas discharges its hormone into the lymph. He also studied the thyroid gland, the thymus and the hypophysis. He was at the same time an excellent diagnostician and physician. He was popular as a teacher. His career brought him many distinctions in the scientific world. He was twice dean of the German faculty of medicine of Prague and a member of many scientific bodies. Because of his sympathies for the socialistic movement, he had many controversies even with his colleagues.

The Exchange of Students

Previous letters have reported the close relations that are developing among the physicians of Slavic nations. The Slavic Congress of Physicians, which will meet in Posen, Poland, in September, testifies to these tendencies. There is a federation of Slavic medical students, which arranges an exchange of Slavic medical students during summer vacations. For next year an exchange of assistants is planned between the different Slavic medical clinics. This exchange is facilitated in the case of Poland and Czechoslovakia because the languages are so similar that no preliminary study is needed for those who want to study in either of the two countries.

Marriages

PERRY A MCGINNIS Pressmens Home Tenn, to Miss Evelyn Olivia Esswein of Nashville, at Paragould, Ark, September 16

THOMAS J HUTTON, Powers Mich to Miss Jean L Gordon of Toronto, Ont Canada in Hammond, Ind, September 22

CHARLES WESLEY LETCHER Wilkes Barre, Pa, to Miss Isabelle Menzies Scott at Fort Fort, October 14

RUTH FRANCIS RASMUSSEN to Mr M Rudolph Campbell, both of South Bend Ind, September 30

ERWIN JOHN HABERLAND Milwaukee to Miss Irene Pamperin of La Crosse Wis September 5

JAMES STEWART HUOSON to Mrs Julia Buhl Kugeman both of Grosse Pointe Mich, October 10

GEORGE L MCCORMICK to Miss Victoria A Mason both of Marshfield Wis, September 7

CLOYO F WHARTON Akron Ohio to Miss Lena Zwickel of Anderson Ind, October 12

HAROLD J DYORAK Minneapolis to DR LAURA M FISHER of Philadelphia September 20

RAYMOND J A DALTON to Miss Joan M Lauderdale both of Milwaukee September 23

THEODORE HARTLEY Bradford Ill to Miss Ethel McCarron of Chicago October 10

NEWTON W FAWCETT to Miss Vera Strong both of Starkweather N D August 26

JOSEPH C SPRINGER South Wayne Wis to Miss Rose Bloom of Beloit October 8

VICTOR H CREMER to Miss Delia Mae Goethe both of Toniah Wis August 31

ROBERT T MC CARTY Appleton Wis to Miss Clara Ewens of Milwaukee recently

Deaths

John Edward Lane ☉ New Haven, Conn, Yale University School of Medicine, New Haven, 1903, studied in universities at Gottingen, Berlin, Gneva and Paris, since 1920, member and at one time chairman of the Council on Scientific Assembly of the American Medical Association, member of the House of Delegates, 1918-1924, 1926-1932, and chairman of the Section on Dermatology and Syphilology, 1924-1925, clinical professor of dermatology at his alma mater, 1920-1922, clinical assistant in medicine, 1907-1910, clinical assistant in dermatology, 1915-1916, and clinical instructor in dermatology, 1916-1920, secretary of the Connecticut State Medical Society, 1917-1920, treasurer of the Congress of Physicians and Surgeons of North America, member and past vice president of the American Dermatological Association, past president of the New York Dermatological Society, the New Haven Medical Association and the Beaumont Medical Club, member of the Societe Francaise de Dermatologie et de Syphiligraphie Paris, chairman of the section on dermatology and syphilis, 1919-1920, New York Academy of Medicine dermatologist to the New Haven Hospital, author of numerous articles on dermatology and history of medicine, aged 61, died suddenly, October 17, of heart disease

Ira Oscar Denman ☉ Toledo Ohio, Hahnemann Medical College and Hospital, Chicago, 1897, member of the American Academy of Ophthalmology and Oto-Laryngology, fellow of the American College of Surgeons chairman of the board of health in Charleston Ill, 1903-1907, at one time on the staff of the Toledo Hospital, formerly on the editorial board of *Archives of Physical Therapy, X-Ray Radium*, aged 61, died, September 28 of heart disease

Bernard Francis McGrath ☉ Milwaukee, Georgetown University School of Medicine, Washington, D C, 1895 Harvard University Medical School, Boston, 1906, formerly dean, professor and director of the department of surgery, Marquette University School of Medicine, member of the Massachusetts Medical Society, fellow of the American College of Surgeons, aged 63, was found dead October 16, in New York, of heart disease

Nathaniel Aldridge Barrett, Decatur, Ala University of Nashville (Tenn) Medical Department 1885, formerly member of the board of education of Birmingham at one time managing director of the Birmingham Baptist Hospital, aged 72 died, September 12, of cerebral softening and hypostatic pneumonia

Claude O Harper ☉ Fort Worth Texas Tulane University of Louisiana Medical Department New Orleans, 1897, past president of the Tarrant County Medical Society, on the staffs of the All Saints Episcopal Hospital and the City and County Hospital aged 61 died August 22, of heart disease

Albert Forrest Longeway ☉ Great Falls, Mont, University of Bishop College Faculty of Medicine, Montreal, Que Canada, 1886 fellow of the American College of Surgeons, at one time secretary of the state board of health, surgeon to the Columbus Hospital, aged 68 died September 4

James S Boyers ☉ San Diego Calif Baltimore Medical College 1882, Jefferson Medical College of Philadelphia, 1883 member of the Indiana State Medical Association, past president of the state board of health of Indiana aged 81, died, October 1 of coronary sclerosis and arteriosclerosis

Edward Joseph De Bergue, New Orleans Tulane University of Louisiana Medical Department New Orleans, 1908 member of the Louisiana State Medical Society for many years member of the state board of health aged 62, died September 19 in the Southern Baptist Hospital

Eleanora Bennett Saunders, Towson Md, Medical College of the State of South Carolina, Charleston 1907 member of the Medical and Chirurgical Faculty of Maryland and the American Psychiatric Association, aged 48 died September 26 in the Sheppard and Enoch Pratt Hospital

Joseph Connor Joyce, Annapolis Md, University of Maryland School of Medicine Baltimore 1908 member of the Medical and Chirurgical Faculty of Maryland health officer of Annapolis aged 48, died September 22 in the University Hospital Baltimore of septic laryngitis

William Cicero Eubanks, Paducah, Ky Pulte Medical College Cincinnati 1892 member of the Kentucky State Medical Association past president of the McCracken County Medical Society, aged 65 died September 27 in the Illinois Central Hospital of heart disease

Hans Christian Jorgenson, San Diego, Calif, George Washington University School of Medicine, Washington, D C, 1906, member of the California Medical Association, served during the World War, aged 58, died, September 9, of suppurative hepatitis and gallstones

Frank C Studley * Milwaukee, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1893, medical superintendent of the Shorewood Hospital-Sanitarium, aged 63, died, September 23, at Marinette, Wis, of cerebral hemorrhage

Gerald Harrison Grout * New York, Columbia University College of Physicians and Surgeons New York, 1902 served during the World War, on the staffs of the Roosevelt and the Herman Knapp Memorial Eye Hospital, aged 53, died, September 25

Frank Gleason Fay, Randolph Mass, Long Island College Hospital, Brooklyn, 1884 member of the Massachusetts Medical Society and the New England Society of Psychiatry, aged 74, died, August 31, in the Massachusetts General Hospital, Boston

Frederick A Achey, Lancaster, Pa University of Pennsylvania School of Medicine Philadelphia, 1886, member of the Medical Society of the State of Pennsylvania, aged 71 died, September 2, in a hospital at Coudersport, of gastric hemorrhages

Louis Henry Enos, Alton, Ill, Hahnemann Medical College and Hospital, Chicago, 1918, member of the Illinois State Medical Society, aged 43 on the staff of St Joseph's Hospital, where he died October 4, following an operation for appendicitis

John Clark Corbus, Jr, Mendota, Ill State University of Iowa College of Medicine, Iowa City, 1884, member of the Illinois State Medical Society, aged 72, died, September 16, in the Washington Boulevard Hospital, Chicago, of pneumonia

Vernon Vivaldo Talcott, Republican City, Neb University of Nebraska College of Medicine, Omaha 1917, served during the World War, aged 41, died August 11, of coronary thrombosis, mitral regurgitation and chronic myocarditis

Lizzie Daniel Rose Atkinson, Cambridge, Mass, University of Michigan Medical School, Ann Arbor, 1891 member of the Massachusetts Medical Society, aged 80, died, September 20, of arteriosclerosis and diabetes mellitus

Samuel Kahn, Detroit Baltimore University School of Medicine 1898 member of the Michigan State Medical Society, on the staff of the Evangelical Deaconess Hospital, aged 64 died, September 26, of coronary thrombosis

J Harry Coates, St Louis Barnes Medical College, St Louis, 1904, member of the Missouri State Medical Association, aged 51, died, September 29, in the Barnes Hospital, following an operation for appendicitis

James H Goad, Gary, Ind Illinois Medical College Chicago 1908 member of the Indiana State Medical Association on the staffs of the Mercy and Methodist hospitals, aged 54 died, September 26, of heart disease

Vincenzo Nuzzo, Chicago Regia Università di Napoli Facoltà di Medicina e Chirurgia, Italy, 1902 member of the Illinois State Medical Society, aged 60 died June 7, of cerebral thrombosis and cerebral hemorrhage

John Ward Gardner, Jersey City N J Bellevue Hospital Medical College, New York 1896 member of the Medical Society of New Jersey, aged 60 died October 1, of diabetes mellitus and cerebral thrombosis

Wade Jesse Lane, Marshall, Texas Tulane University of Louisiana Medical Department, New Orleans, 1886 member of the State Medical Association of Texas, aged 73 died, June 13, of cerebral hemorrhage

Charles Jones Gose, Kinderhook, Ill Missouri Medical College, St Louis 1899 formerly postmaster of Kinderhook, aged 61 died, September 22, in the Blessing Hospital, Quincy of a self inflicted bullet wound

Ora Isaiah Tower, Los Angeles University of California Medical School, Los Angeles 1910 member of the California Medical Association, aged 47, died September 4, in Newport Beach, of angina pectoris

Arthur Lefebvre, Detroit, School of Medicine and Surgery of Montreal Que Canada, 1894 aged 65, died, September 25 in the Grace Hospital, of dilatation of the heart uremia and prostate hypertrophy

James Constant Reynolds, Lake Geneva Wis Rush Medical College, Chicago 1870 formerly state senator for many years bank president, member of the school board, aged 84, died, September 3

Arthur Pell, Rye, N Y, Bellevue Hospital Medical College, New York, 1876, aged 80, died, September 27, in the Northern Westchester Hospital, Mount Kisco, of carcinoma of the tongue and larynx

Henry E Goldberger * Chicago, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903, aged 63, died, September 23, of carcinoma of the bladder

Frank Theodore Noeson, Niobe, N Y, University of Buffalo School of Medicine, 1885 member of the Medical Society of the State of Pennsylvania, aged 71, died, August 29, of pneumonia

Robert S Bole, St Paul, University of Vermont College of Medicine Burlington, 1884 an affiliate fellow of the American Medical Association, aged 73, died, September 16, in St Luke's Hospital

Samuel Melville Wolfe * Wilkes-Barre, Pa, Jefferson Medical College of Philadelphia, 1894 past president of the Luzerne County Medical Society, aged 65, died, October 4, of heart disease

Samuel Black Hall * Clinton, Tenn, Tennessee Medical College Knoxville 1893, past president of the Anderson County Medical Society, aged 69, died, September 30, of cerebral arteriosclerosis

William Hale Currier, Worcester, Mass, Dartmouth Medical School Hanover, N H, 1881 member of the Massachusetts Medical Society, aged 76, died, September 28, of arteriosclerosis

Jerre George Lynch * Los Angeles Cooper Medical College San Francisco 1906, on the staff of the Hollywood Clara Burton Memorial Hospital, aged 55, died, September 18, of heart disease

Joseph Milton Lawson * Sidney Ill, University of Michigan Medical School, Ann Arbor 1885, aged 75 died September 25 in the Burnham City Hospital, Champaign of cholecystitis

Charles Calhoun Carson, Talbotton Ga Hospital Medical College Atlanta 1911 aged 47 died September 28 in the City Hospital Columbus of injuries received in an automobile accident

John T Elliott, Rhinelander Wis, Trinity Medical College Toronto, Ont, Canada, 1900 health officer of Rhinelander, aged 62 died September 19, in Merrill, of heart disease

Charles H Reigrod, New York Long Island College Hospital Brooklyn, 1905 member of the Medical Society of the State of New York, aged 62 died, September 22, of heart disease

Henry Alfred Nex, Allegan Mich Chicago College of Medicine and Surgery 1917 member of the Michigan State Medical Society, aged 40 died, August 22, of acute myocarditis

John C Crilly, Philadelphia University of Pennsylvania School of Medicine, Philadelphia 1886 aged 70 died, September 28 of carcinoma of the liver and diabetes mellitus

William Edwin Carpenter, Tama, Iowa Rush Medical College Chicago, 1895 member of the Iowa State Medical Society, aged 63, died September 27, of heart disease

Charles Wonson Eveleth, New York Harvard University Medical School Boston, 1903 aged 55 died, October 8, in the Presbyterian Hospital of cerebral hemorrhage

Charles Brace Hewitt Hanvey, Berkeley, Calif McGill University Faculty of Medicine Montreal, Que, Canada, 1883, aged 77 died September 15 of cerebral hemorrhage

E N Lowe, Oxford Miss Tulane University of Louisiana Medical Department New Orleans 1892 aged 69, died, September 12, of chronic myocarditis and hypertension

Mary Jane Green, Los Angeles Kansas City (Mo) Homeopathic Medical College 1890, aged 77, died, September 8, of arteriosclerosis and cerebral hemorrhage

David Alexander Rodger, Cowansville, Que Canada University of Bishop College Faculty of Medicine Montreal, 1897 died, June 17 of coronary thrombosis

Charles William Hollnagel, Chicago Chicago College of Medicine and Surgery, 1913, aged 58 died September 26, of chronic myocarditis and coronary occlusion

Lars Porsenna Solsness, Weymouth, Mass College of Physicians and Surgeons Boston, 1916 aged 66, died, September 19

William Josiah Fairfield, Denver, Bellevue Hospital Medical College, New York, 1878, aged 80, died, August 30, of cerebral hemorrhage and skull fracture

Charles Joseph Simon, San Francisco, University of Oregon Medical School, Portland 1922, aged 36, died, September 10, of appendicitis and peritonitis

John Robertson Bissell, Tunkhannock, Pa., Jefferson Medical College of Philadelphia, 1891 aged 60, was killed, September 12, in an automobile accident

Robert Harry Daniel, Dallas, Texas, Southern Methodist University Medical Department, Dallas, 1913, aged 58, died, September 28 of coronary occlusion

John Adams Van Valzah, Daytona Beach Fla Medico-Chirurgical College of Philadelphia 1898, aged 66, died, July 27, of myocarditis and nephritis

David Wasserman, Philadelphia Medico-Chirurgical College of Philadelphia, 1910, aged 60, died September 17, of thrombosis of the coronary artery

Foster P Key, Green Cove Springs, Fla., Atlanta (Ga.) College of Physicians and Surgeons, 1903 aged 60 died, September 6, of angina pectoris

Charles S Nelson @ Springfield, Ill., Missouri Medical College, St Louis, 1891, aged 73 died September 18, in a local hospital, of pneumonia

Thomas McCullough, Chatsworth, Ont., Canada, Trinity Medical College, Toronto 1884 L R C P, Edinburgh Scotland, 1884, died August 8

Vincenzo D'Elia, New Haven, Conn Regia Università di Napoli Facoltà di Medicina e Chirurgia, Italy, 1886, aged 72, died, October 6, of uremia

Frank Henry Russell, Eldred Ill., College of Physicians and Surgeons, Keokuk, Iowa 1888 aged 70 died, September 10, of chronic nephritis

Julia A Ingram, Louisville Ky, Woman's Medical College of Pennsylvania, Philadelphia 1882, aged 81, died, September 23, of heart disease

Amos E Smith, Walkersville W Va., College of Physicians and Surgeons Baltimore, 1909 aged 60 died July 31, in a hospital at Baltimore

Henry Marshall Harrison, La Porte Texas, College of Physicians and Surgeons, Keokuk Iowa 1877, aged 81 died September 22 of senility

Edgar R Borley @ South Bend, Ind., Detroit College of Medicine 1898, aged 62, died October 4 of arteriosclerosis and chronic myocarditis

Thomas A Mitchell, Owensville, Ohio Medical College of Ohio, Cincinnati, 1876, aged 82 died September 25, of cerebral hemorrhage

William Preston Wilson, Onaga, Kan., Kansas City (Mo.) Medical College, 1897 aged 61 died August 10, of chronic myocarditis

Cyrus H Leslie, Palmyra Pa University of Pennsylvania School of Medicine Philadelphia 1874, aged 92, died, July 5 of senility

James Hovey Bullard, Los Angeles, Harvard University Medical School, Boston, 1881, aged 77, died September 20, of heart disease

Edmund James Johnstone, Sydney, N S Canada, Bellevue Hospital Medical College New York 1882 aged 75, died July 13

Bureau of Investigation

FISHEROPATHIC COLLEGE ASSOCIATION

A Denver Fraud Is Debarred from the Mails

The Fisheropathic College Association is a name applied to a mail-order quack concern having for its president and treasurer George B Fisher, for its vice-president Richard V Fisher, son of George B, and for its secretary Anna L Fisher, sister of George B

George B Fisher is a particularly blatant quack who for years has been exploiting the public. In 1911 Denver newspapers reported that Fisher had been found guilty in the federal courts of sending obscene matter through the mails to the "wives of two prominent Denver business men." It was reported at the time that the judge before whom Fisher was tried gave the quack a scathing arraignment, stating that 'a man who was guilty of the practices of which Fisher had been convicted was of the lowest species of humanity and not fit to mingle with decent and respectable people.' Papers at the same time reported that some time prior to this conviction, Fisher had been charged with defrauding an aged and infirm woman out of \$15,000 in notes and securities. A suit against him in the District Court according to the same report resulted in these notes and securities being restored to the aged woman.

In 1923 the Department of Agriculture issued a Notice of Judgment declaring Fisher's nostrums ("Uterine Tonic" and 'Kidney Food') misbranded under the National Food and Drugs Act. The federal authorities declared the Uterine Tonic misbranded because it was fraudulently represented as an

effective cure for "lack of passion," absence of menstrual flow cancer of the uterus, gonorrhea and various other conditions

George B Fisher has claimed to be the "only diagnostician in the world making a chemical and psychological diagnosis." A case was brought to the attention of the Bureau of Investigation some years ago of a young woman unmarried, who was pregnant and who got in touch with Fisher. Fisher diagnosed her case as one of infantile womb, malnutrition, catarrh of stomach, and retroversion. He said that the "bloating" was due to the conditions mentioned and added that the case "suggests a dropsical inclination." He urged her to "lose no time in ordering the \$10 Fisheropathic Home Special."

Fisher has claimed that his "remedies are foods, not drugs." The memorandum of Horace J. Donnelly, Acting Solicitor for the Post Office Department, to James A. Farley, Postmaster General on the Fisheropathic College Association states that while the Fisher group puts out a number of preparations, the principal remedies are "Pugilitis-Pendicitis," "Uterine Tonic Knowledge," "Generative Invigorant" or "Venereal Tablets."

After Dinner Gems," "Sanitary Suppositories" and "Dyscrasia Remedy." It was brought out by the federal investigators that Pugilitis-Pendicitis was mainly epsom salt, with a small amount of baking soda, some citric acid and table salt dissolved in fruit juices flavored with extract of peppermint. The experts for the government testified that this mixture if given in some cases of acute attacks of appendicitis, would be about as dangerous as could be conceived.

The Digestive Gems put out by Fisher were composed of senna red pepper, table salt powdered charcoal glycerin and oil of peppermint. Fisher's advertising declared that his Digestive Gems contained vegetable phosphates which would "eliminate catarrh heart disease, bronchitis asthma and various other conditions." They were also claimed to heal cancerous stomachs.

Fisher also sold what he called "Columbine Massage Cream," which he claimed would when applied externally develop the bust, remove wrinkles and freckles, cure eczema, ringworm, prickly heat and shingles, while if taken internally would cure pneumonia, influenza, whooping cough and asthma! The federal chemists found that the stuff was made of mineral oil, white wax and paraffin.

Fisher's Sanitary Suppositories were said to require neither douche nor enema and could be used by men, women and children. They were recommended for rectal or vaginal cancer, blood poisoning, fistulas, inflammation of the colon, prostate and bladder and for various other conditions. The composition of this therapeutic wonder was found by the federal chemists to be our old friend epsom salt put up in gelatin capsules.

A woman who wrote to the Fisher concern was sent a typical symptom blank containing some sixty-seven questions that were to be answered. One of the questions asked was "Are you jealous?" which was answered in the negative. The other replies stated that the patient was born in 1883, that her height was 6 feet 11 inches (11) and her weight 185 pounds, that she had two children living, that she did not know whether or not she had any "brick-dust" in the urine, she had no lumps under the arms or on the breast, groin or neck, that she occasionally sweated at night, that she did not practice self-abuse or the Fisheropathic breathing exercises, had a fairly good stomach, digestion and appetite had no dizziness, was not inclined to vomit, only bloated after eating to excess, that she had occasional pains around the heart that her beverages were water or milk, that she had a good memory, her sleep was refreshing, she had never had a venereal disease, she did not know whether her doctor was a homeopath or an allopath, she had been vaccinated, was not easily prejudiced, was not averse to Christian science and that the medicines she took were those her doctor had given her and that she sometimes used a douche containing a small amount of salt.

In response to this filled-out symptom blank, Fisher diagnosed her case as "most critical and important." He then continued:

The mother of 2 children just past your 50th birthday and still menstruating passing thru the change of life or menopause makes your case not difficult to treat but indicates your whole system is depleted and in need of scientific care. The right ovary is full of inflammation and being so close to the appendix has saturated the whole system with poison and the womb is so low and prolapsed that a constitutional treatment would be wisest and best and most economical. Send at once for the \$15.00 emergency order to be used in the home.

In this order I will include our Dyscrasia Remedy for enriching and purifying the blood. Our PPP for intestinal sanitation.

Our Sanitary Suppositories to be used in the rectum together with other Medications suggestions in Diet and an Exercise for strengthening the walls of the stomach so that the ovaries and appendix may be permanently benefited.

The "Dyscrasia Remedy" was said to contain echinacea. The "other medication" referred to in the quotation was Fisher's "Gastric Assimilator," which was an alcohol-water solution of sugar, fruit juices, citric acid and oil of peppermint.

Judge Donnelly's memorandum also brings out that Fisher's "Uterine Tonic Knowledge," which was advertised as a "scientific oxygenator and tissue builder" was composed of ammonium iodide, a carbonate, glycerine, formaldehyde and spirits of cloves. This was offered as a "perfect deodorant in blood poisoning" and for uterine cancer. It was further brought out that Fisher is not a graduate of any medical school and had in fact, been fined for violating the medical practice act. Judge Donnelly on September 25 recommended to the Postmaster General that a fraud order be issued against the Fisheropathic College Association and its officers and agents as such. On September 26 the mails were closed to this fraud.

Foci of Yellow Fever in South America—In South America, three main foci of the disease are known: the north-west portion of the continent, where there was an epidemic in Morocco, Colombia, in 1929; the eastern states of Brazil where a severe outbreak occurred in Rio in 1929, and the southern tropical regions where there has recently been an outbreak in the war zone of the Chaco. But it is held probable that the disease is endemic throughout the vast area that lies between these known foci.—Still John *J. Roy. Army M. Corps* 61 268 (Oct.) 1933.

Correspondence

SPINAL ANESTHESIA IN HYPERTENSION

To the Editor—So many conflicting statements have been attributed to my remarks in regard to the therapeutic use of spinal anesthesia for the emergency relief of certain types of hypertension (Combined Meeting of the New York Society of Anesthetists and American Society of Regional Anesthesia, Misericordia Hospital, New York, April 11) that I have considered it advisable to make this brief statement preliminary to a series of cases treated by this method which will be reported in detail rather shortly.

The depressor phenomenon of spinal anesthesia, so far as it relates to clinical blood pressure, has long been known to surgeons, in fact, the sudden drop in blood pressure accompanying this type of anesthesia led many surgeons to abandon its use in the early days of its employment.

In a study of some 3,000 spinal anesthesia records made in 1931, several striking and interesting facts were demonstrated, from these, certain observations are permissible. Some drop in both systolic and diastolic blood pressure levels occurred in about 92.4 per cent of all the surgical cases in which spinal anesthesia was employed. This fall in pressure averaged from 10 to 38 mm. of mercury in most of the patients exhibiting no cardiovascular disease. In individuals with high blood pressure levels however, the depressor effect of the spinal anesthesia was more marked, with certain exceptions it was found that the higher the systolic level the greater the fall in pressure. Such drops in systolic levels may be quite extreme, in one instance there was a fall from 260 to 110, while in another it was from 248 to 128. In practically all the cases with a pre-operative systolic level of 220 and above, there was a drop of 50 or more millimeters of pressure.

With these facts in mind, it occurred to me that, while this depressor effect of spinal anesthesia might be undesirable from a surgical point of view, it offered a possible source of therapeutic relief in instances in which a sudden dropping of the systolic blood pressure level was to be desired. Such, for example, are those cases of arterial hypertension approaching the prodromal phase of cerebral hemorrhage, while venous section may at times be life saving in these instances, the secondary anemia frequently associated with this condition may be markedly enhanced by the removal of large quantities of blood. Moreover, the actual fall in systolic blood pressure even with the removal of from 500 to 1,000 cc. of blood is not very great, a drop of from 30 to 50 mm. is perhaps the maximum to be anticipated. Any method, therefore, that will cause a rapid drop of pressure without actual loss of blood volume should be carefully considered.

The first patient treated by spinal anesthesia was a man aged 58, with all the signs and symptoms of an oncoming cerebral hemorrhage, his blood pressure on admission to the hospital was 244 systolic and 120 diastolic. He was given three eighths of the usual dose of spinal anesthesia (Lazarus, J. A., Pick, C. J., and Rosenthal, A. A. *Tropacocaine Hydrochloride in Spinal Anesthesia* *Ann. Surg.* 97 757 [May] 1933) and within twenty minutes the pressure had fallen to 180/110, ten minutes later the figures were 168/105. There were no untoward cardiac signs and within an hour nearly all the previous symptoms with the exception of the posterior headache had cleared up. Blood pressure observations taken every four hours for the next week showed a slow rise in the systolic component to about 210. The patient however, remained free from symptoms for several months. This case was followed by eleven others of the same type and with the same general response.

The indications for this type of emergency therapy are rather clearly defined, in cases of extreme hypertension exhibiting

prodromal signs of oncoming apoplexy and with relative grades of anemia, spinal anesthesia may be life saving. The method is less valuable in cases of obvious cardiac failure, marked edema and dyspnea are definite contraindications.

While I claim no special priority in the adaptation of this undesired complication of surgical spinal anesthesia as a positive therapeutic measure in clinical medicine, I have found no reference to its use in the literature prior to my remarks on April 11.

and Prevention of Heart Disease, Beth
David Hospital

ANOTHER NAME FOR DELIRIUM TREMENS

To the Editor—While visiting in rural Virginia last summer, I came on a new name for an old malady. At least I had not encountered it before. Our Negro cook announced deep concern over the illness of her adult son. She called it "mannaprocher." "You know it comes from drinkin'," she said. A brief inquiry as to her son's symptoms showed his trouble to be our old friend the D. T.s.

Of course it immediately suggested itself that the name was a corruption of *mania a potu*. Thinking it possible that this version was personal to the cook, I determined to seek confirmation of its position in the local vocabulary. There was in the neighborhood a Negro of 65 or more, intelligent, well informed and reliable. Under pretext of buying eggs from his wife, I called. While exchanging greetings with him I incidentally asked him if he had ever heard of a disease of the above name.

Yes, he had heard of it all his life. I made him repeat the name, and his version coincided exactly with that of the cook. It came from too much whiskey. Folks that had it acted all kinds of foolish ways, and you couldn't do nothin' 'tall with 'em. They ought to be knocked in the head.

I had thought that I was pretty well up on Negro vernacular, but this was a new one on me. Doubtless other readers of *THE JOURNAL* have met with it.

B. M. RANDOLPH, M.D., Charlottesville, Va.

THE ASCHHEIM-ZONDEK TEST IN THE DIAGNOSIS OF HYDATIDIFORM MOLE

To the Editor—Dr. Dabney and associates (*THE JOURNAL*, September 2, p. 771) stress the need of revising the Aschheim-Zondek test in differentiating between hydatidiform mole and threatened or inevitable abortion. The authors correctly quote from *Clinical Endocrinology of the Female*: "Aschheim obtained a positive pregnancy reaction in a case of hydatidiform mole with one twelfth the amount of urine usually necessary to secure such a reaction."

In cases of bleeding during the first trimester of pregnancy associated with disproportionate enlargement of the uterus the patient's urine should be diluted about ten or twelve times with water before it is injected into the test animals.

Lack of emphasis on the phrase "the amount of urine usually necessary to secure such a reaction" is responsible for considerable confusion in the use of the Aschheim-Zondek test in the diagnosis of hydatidiform mole and chorio-epithelioma.

The amount of urine necessary to produce a pregnancy reaction in the mouse or rabbit varies with the term of pregnancy. In very early pregnancy (five or ten days after the missed period) I employ a total of 24 cc. in the immature mouse and from 10 to 20 cc. in the isolated rabbit because the quantity of the anterior pituitary like substance present in the urine at

this stage of pregnancy is no more than a half mouse unit per cubic centimeter. Dr. Dabney's patient was a little more than four months pregnant, the peak of the hormone production. One cubic centimeter of her urine then contained approximately five mouse units of the hormone, enough to give a reaction in the nonestrous isolated rabbit.

In testing for hydatidiform mole, the term of pregnancy must be taken into account. Usually only 1 cc. of the patient's urine is diluted twelve times and injected into an isolated rabbit. Moreover, the twenty-four hour specimen should be employed, as the concentrated morning specimen contains higher values. The original mouse test is more reliable than the Friedman modification, since one can thereby determine accurately the number of mouse units of the hormone present in a cubic centimeter of urine.

Dr. Dabney and his associates obtained a positive reaction with as little as 0.4 cc. of the patient's urine. This may have been due to one of the following factors: An unusually high excretion of the hormone, as suggested by the authors, a high concentration of the patient's urine, or the unintentional employment of an estrous rabbit, which is more sensitive to the hormone than the nonestrous rabbit.

CLIMATE AND THE INCIDENCE OF COMMON COLDS

To the Editor—Is it possible for you to tell me what the relative incidence of ordinary colds and their complications is as between the New England states and Florida? An inquiry from a patient of mine is this: "If I take my children to Florida this winter are they less likely to get colds or bronchial disturbances than if they stay in Boston?" Your answer would be gratefully appreciated. JACOB FINE, M.D., Boston.

ANSWER—Since the common cold is of world-wide occurrence, one would expect much authentic information on the relative incidence of common colds in different climates. There are few such reports available, however, and in these the conclusions differ. Popular opinion for centuries has held that the weather is an important influence in the cause of common colds. Hippocrates is quoted by J. G. Townsend (*A Review of the Literature on Influenza and the Common Cold*, supplement 48, *Public Health Reports* 1924) as having written that if the summer be dry and northerly and the autumn rainy and southerly, headaches occur in winter, with coughs, hoarseness, coryzae, and in some cases consumptions, but if the autumn be northerly and dry it agrees well with persons of a humid temperament and with women, but others will be subject to dry ophthalmies, acute fevers, coryzae, and in some cases melancholy. A less remote opinion on influenza was expressed by Noah Webster in 1799 (*History of Epidemic and Pestilential Diseases*, volume 2). He said: "Epidemic catarrh is the disorder which most decisively proves a rapid and universal change in the essential properties of the atmosphere. This disease sometimes invades the human race so suddenly that half the inhabitants of a town or city are seized in a night. It is evident that the disease is occasioned by an alteration in the atmosphere, but it is observable that whenever it appears on the American continent it appears also in the islands of the West Indies. In autumn northerly breezes are experienced in the islands and these produce colds and coughs similar to what we all experience in temperate latitudes on the change of weather in spring and autumn. But these are very different, at least in degree, from a general epidemic influenza, which seizes mankind in all climates with pain in the side and bones, accompanied often with fever. The universality of this disease, bursting suddenly upon all climates and raging with equal violence in all seasons and in defiance of heat or cold leaves us no room to question its dependence on some other cause than changes of weather or application of cold."

W A Wells (Influence of the Atmosphere in the Causation of Colds, *South M J* 18 139 [Feb.] 1925) reviewed the statistics of Professor Schade on the German Army covering an analysis of almost three fourths of a million cases of disease of the upper air passages. It was demonstrated that the cases increased regularly with the fall of the thermometer, and that colds were from two to eight times more frequent in winter than in summer. In the excessively cold winter of 1916-1917, the number of colds was three times greater than the number in ordinary winters. A study of the common cold by investigators at Johns Hopkins University has been under way for several years. W M Gafafer (Upper Respiratory Disease [Common Cold] and the Weather, Baltimore, 1928-1930, *Am J Hyg* 13 771 [May] 1931) reported a study by this group of several hundred volunteers, in which an effort was made to determine what relation exists between deviations from "normal" of the weekly upper respiratory attack rates and the deviations from "normal" of each of thirteen weather elements. The period of observation of eighty-two weeks was relatively short. Nevertheless the study strongly suggested that changes in weather during a warm season are probably more frequently associated with disease of the upper respiratory tract (common cold) than changes in weather during a cold season. L I Dublin (One Year of Common Colds and Associated Infections *Stat Bull Metrop Life Ins Co* November, 1923) presented statistical evidence of a relation between temperature of the outside air and the incidence of colds. He said "A drop in the weekly mean temperature of 10 degrees carries with it an increase of eighteen common colds per week in this group of 6,700 people." D F Smiley (Seasonal Factors in the Incidence of the Acute Respiratory Infections *Am J Hyg* 6 621 [Sept.] 1926) in reviewing the incidence of acute respiratory infections over a twelve year period among students at Cornell University, wrote "There is apparently a definite reciprocal relationship between the incidence of the acute respiratory infections and the mean outside atmospheric temperature." An unusually extensive review of the literature by the Thomsons was published recently for the Pickett-Thomson Research Laboratory of London. In compiling this large volume, the reviewers extracted information from more than 2,000 research papers on the common cold. In chapter XXX is reviewed the literature on the part played by chill in the causation of colds. The authors, who themselves have done careful research on the common cold for fifteen years, do not hesitate to say that the incidence of the common cold is almost entirely a matter of climate and more especially of temperature.

There are however, reports of research on the other side of the question. In a study of the incidence of colds among students at universities located in different parts of the United States, W H Barrow (Group Susceptibility to Acute Upper Respiratory Tract Infections, *THE JOURNAL* Sept 18, 1926, p 920) found at Stanford University in California, where the climate is mild, that practically the same number of students for each hundred investigated suffered from acute colds as did those at Harvard University in Massachusetts where the climate is rather rigorous. Townsend, of the U S Public Health Service conducted a study of a large group mostly of students of colleges and of another group composed of medical officers of the Army, Navy and Public Health Service and members of university faculties. The universities were scattered as far as Boston, New Orleans, Chicago, Tucson, Salt Lake City and Berkeley, and the reports covered a period of more than eighteen months. The incidence of colds at the ten universities was found to be remarkably uniform, there being only two instances, the Salt Lake City group and the Washington group in which the attack rate deviated by as much as 20 per cent from the mean rate of all groups in the same period. Considering the wide difference in climates of the localities represented, the uniformity of attack rate was considered one of the most significant facts brought out by the study, indicating that climate is a factor of much less importance than would be supposed. There was surprisingly little evidence of consistent differences between the localities with respect to incidence rates.

One could go on reviewing the observations and conclusions reported by those who have made special studies on the common cold, but there would still be no general agreement as to the guilt or innocence of climatic factors. The literature on the common cold is chaotic and until order is brought out of this situation the advice given several years ago (*Climate and Common Colds* Current Comment *THE JOURNAL*, Oct 9 1926, p 1218) is still good. The methods for prevention and measures for protection may well be based on common sense hygiene rather than specious theories.

TREATMENT OF HABITUAL ABORTION

To the Editor—A white married woman is desirous of children but has miscarried in each of her two pregnancies between four and five months. Pregnant the first time in 1929 she became very ill with edema of the lower extremities, high blood pressure, headaches and albumin in the urine and passed a macerated fetus during the fifth month. Her second pregnancy occurred in 1933 and although she showed no symptoms at all like the previous time (the blood pressure remained normal and there was no albumin in the urine), nevertheless the fetus died the fourth month and was passed with membranes intact. This occurred four months ago and on examination today I can find no explanation that is completely satisfactory. The age of the patient is 28, the weight 130 pounds (59 kg). Physical examination is essentially negative as is pelvic examination. The hemoglobin is 75 per cent, red blood cells 3,600,000, white cells 8,500. The urine is negative for albumin or casts. The phenol sulphophthalein test for kidney function shows 90 per cent excretion in two hours. The menstrual history is absolutely regular. In the past history the patient states she remembers having swollen feet at the age of 16 which disappeared after the prescription of proper shoes by an orthopedist. At 21 the patient had an attack of tuberculosis which was cured after five months in a sanatorium and has never had any symptoms relative to the old tuberculosis since. To all appearances she looks and feels perfectly well (except for slight anemia). She wants to know whether she has any chance of having a live birth or whether she must stop trying and resign herself to her fate. If she becomes pregnant again is there not some danger of her becoming eclamptic? Are there any further examinations indicated? The Wassermann reaction is negative. I would appreciate any suggestions as to possible etiology or treatment. Please omit name.

M D New Jersey

ANSWER—The fact that the patient has had two miscarriages does not imply that she will have more. Since the patient is only 28 years old there is no harm in suggesting that she wait at least one year after the last miscarriage before becoming pregnant again. In the meanwhile the anemia, which is more than slight, should be overcome by the customary means, including diet and iron and arsenic preparations. A careful examination should be made to try to detect a possible focus of infection in the body. It is unfortunate that the fetus and placenta were not studied bacteriologically, especially because the fetus was obtained in intact membranes in the second pregnancy. Both husband and wife should follow a fairly regular mode of living and build themselves up physically. Their diet should contain abundant fresh vegetables, fruit, calcium, milk and vitamins, especially E.

If the toxemia that was present during the first pregnancy had caused a permanent injury to some organs such as the kidneys, evidence of this would have most likely appeared during the second gestation. Since this evidence failed to appear, there is no reason to believe that a toxemia will necessarily again manifest itself in subsequent pregnancies. However, it is highly advisable to perform more tests of kidney function before another pregnancy supervenes although not infrequently only a pregnancy will reveal latent kidney damage.

When the woman again becomes pregnant she should be seen about once a week, at which time the usual prenatal examinations should be made. In addition the patient should be advised to be inactive during that period of each month when she would have menstruated if she were not pregnant. Intercourse should be restricted as much as possible. It is advisable to prescribe a proper diet and to give iron and arsenic for stimulation of hematopoiesis.

Success has been noted in some cases of habitual abortion by the use of corpus luteum both orally and hypodermically. This therapy is based on the fact that the corpus luteum has a protective influence on the young ovum and a quieting effect on the uterine musculature. If the patient has a thyroid deficiency, thyroid preparations also should be prescribed.

EFFECTS OF SODIUM BICARBONATE IN HYPERACIDITY

To the Editor—A patient of mine suffering from frequent attacks of severe nervous hyperacidity for which alkalis gave him but poor relief has been resorting to washing out his stomach every night in order to avoid being awakened by the acute heartburn. He uses sodium bicarbonate and plenty of hot water and is able to achieve a pretty thorough gastric lavage without any strain or the use of mechanical aids. He has no pain and the roentgen examination is negative. I should like to know what deleterious effects if any may result from this practice if long continued. The patient is a middle-aged man of normal weight and strength and has no other complaint except a nervous extrasystole. Please omit name.

M D New York

ANSWER—No deleterious effects will ordinarily result from this procedure. It is conceivable that should too large quantities of soda be used and the pyloric sphincter relax, absorption of the soda from the intestinal tract might lead to symptoms of mild alkalosis. This however, is rather remote. Again the continuous use of soda may lead to subsequent increase in the hydrochloric acid response.

IMMUNIZATION METHODS IN HAY FEVER

To the Editor—Can you advise me who may be given the credit for introducing specific vaccines (pollen antigens) for hay fever and in what year?
M D Maryland

ANSWER—Thommen, in the book on Asthma and Hay Fever, by Coca Walzer and Thommen says "To Noon is due the credit of having been the first to establish the active immunization therapy of hay fever on a practical and scientific basis. His method consisted of the subcutaneous injection of definite quantities of timothy pollen extract the dosage of which he endeavored to control by the ophthalmic reaction. This work, interrupted by Noon's untimely death was carried on by Freeman."

Noon and Freeman published a report of their results in 1911. Active immunization had been attempted by Dunbar, in 1903, Curtis in 1900, and Scheppegegrell in 1909, but these attempts were abandoned because of the severity of the reactions and the irregularity and uncertainty of the results.

Numerous investigators carried on the work and introduced the use of extracts of ragweed and tree and other pollens as well as that of timothy.

It might be well to mention here that the treatment for hay fever in common usage today consists in giving subcutaneous (or intracutaneous) injections of the extracts of the responsible pollens. The solutions are not vaccines nor are they serums, as no bacteria and no serums are involved.

CHANCES OF SURVIVAL OF PREMATURE INFANT—
URTICARIA IN THE NEWBORN

To the Editor—It is commonly believed by the public that premature infants say of seven months have a lower mortality than those of eight months. Please discuss briefly stating the percentage of mortality in each case. It is also common belief that the erythematous condition with which infants are born or which develops a few hours or days later is hives or bold hives as people call it and that it is essentially necessary for these infants to break out with this condition or else they die. As a result the infants are dosed with teas and the like. Please discuss briefly. I am asking for your views in this matter hoping I may convince some who are wrong. Please omit name.
M D Texas

ANSWER—Every day that a fetus is carried in the uterus under normal circumstances adds to its opportunity for life. This discards any thought that a seven months fetus under ordinary circumstances has anything like the opportunity for life that one has that has been carried eight months. In discussing the possibilities for life in premature infants the facts surrounding the individual premature delivery must be given due consideration. This is especially true of chronic infections in the mother the age of the mother and whether the pregnancy is single or multiple.

In a well regulated institution so called hives or bold hives developing shortly after delivery are exceptional. Such a condition is not uncommon in some of the toxemias of pregnancy but is more often due to the treatment of the skin of the new-born infant either by irritating solutions or by external applications of various medicated oils or ointments. These early irritations are not to be confused with those developing later in infants which may be due to many causes among the most common being toxemias due to ingredients in the mother's milk artificial feeding or underlying factors causing icterus, as well as external irritants.

USE OF COVALESCENT SERUM IN POLIOMYELITIS

To the Editor—Please inform me whether antipoliomyelitis serum is available to the profession. Is it worth while giving it as long as the patient has fever or must it be used in the first four or five days to be of value? Is the present epidemic of encephalitis in St. Louis supposed to be due to the same or a related virus?

CHARLES C HINTON, M D Macon Ga

ANSWER—Convalescent poliomyelitis serum is available to the profession in different parts of the United States through the establishment of convalescent serum centers either by boards of health or through private endowment. These centers however do not furnish a complete service throughout the entire country.

The opinion of investigators is divided as to the value of convalescent poliomyelitis serum in the treatment of patients with this disease. It is generally agreed that whatever value it might have is greatest when the serum is administered in the preparalytic stage. Some investigators believe that once the stage of paralysis has been reached no benefit results from the use of serum. Other investigators on the basis of clinical observation believe that any individual still in the active febrile stage of poliomyelitis should be given the benefit of convalescent

serum treatment. It is believed, therefore, by some that the convalescent serum may inhibit or prevent the progress of the disease but paralysis that has resulted from destruction of nerve cells, of course, cannot be relieved.

The cause of epidemic (lethargic) encephalitis has not been discovered but it is supposed to be a different etiologic agent from the filtrable virus causing poliomyelitis. Because of a similarity in the pathologic changes in the central nervous system in the two diseases, many investigators believe that the causes of these two diseases are similar but not identical.

HERNIA AFTER APPENDECTOMY

To the Editor—What is the best surgical opinion regarding the post operative occurrence of right inguinal hernia following a McBurney grid iron incision as compared with a right rectus incision in which the rectus muscle is split instead of retracted?

JOHN M SIMPSON, M D Marshfield Ore

ANSWER—Griffiths, in 1919, reported eleven inguinal hernias following appendectomy, ten of which occurred on the right side and one on the left. The incision employed for removal of the appendix was of the McBurney muscle-splitting type in all but one case in that one case a right rectus incision was made, and the muscle was retracted instead of being split. These eleven cases occurred among 100 consecutive cases of hernia. The occurrence of the hernia from the date of appendectomy was from a few months to three and a half years.

Roberts reported twenty right inguinal hernias following appendectomy in which a McBurney incision was used. These cases were found among 6000 cases of hernia. Roberts was of the opinion that hernia did not follow a right rectus incision. In other words his opinion was that there is a definite relationship between the McBurney incision and subsequent development of inguinal hernia.

Southam expressed the opinion that injury to the branches of the ileo-inguinal nerve internal to the anterior-superior iliac spine in the McBurney incision is possibly the cause of many inguinal hernias, since it produces paralysis of the muscle and the conjoined tendon around the internal ring. He stated that three patients with right inguinal hernia which followed the McBurney incision were operated on for repair of the hernia and at the same time sections of the ileo-inguinal nerves were removed from the canal. Histologic examination disclosed partial degeneration in two cases.

Adler has also noted that inguinal hernia not infrequently follows appendectomy when the McBurney incision is employed.

Unquestionably, appendectomy is many times carried out through McBurney incision without subsequent development of hernia. Although there is some evidence that inguinal hernia does develop following this type of incision it seems obvious that the McBurney incision may well be used if the function of the ileo-inguinal nerve is not impaired.

KETOGENIC DIET IN BACILLURIA

To the Editor—Can you give me references that will assist me in the question of diet suggestions to secure ketonuria in the handling of a case of severe bacilluria (colon bacillus)? I know that the Mayo Clinic recommends this method of attack but I would like to get more details for a patient who cannot go into a hospital now under a dietitian's management. In other words how to get ketonuria in the ambulatory case?

GEORGE WATT, M D New York

ANSWER—The ketogenic diet in the treatment of bacilluria was begun by Clark and by Helmholz of the Mayo Clinic. It was known that colon bacilli are inhibited from growing in urine at a pH of 4.6 to 5.0 and Barborka suggested that a ketogenic diet would produce urine of such a pH. Investigators at the Mayo Clinic then demonstrated that patients in ketosis do excrete bactericidal urine. Two factors are necessary in the treatment of bacilluria with the ketogenic diet: ketonuria and a low pH of the urine. The bactericidal power of ketonurine does not vary directly with the degree of acidity; however, nor is it due to the presence of diacetic acid or sodium diacetate. Normal urine of pH 4.8 does not have antibacterial powers. Ketonurine of pH 5.7 or higher does not have bactericidal properties. Ketonurine must have a pH of 5.6 or below in order to be therapeutically effective. Acidity in synergy with some substance in ketonurine is believed to be responsible for the bactericidal action. Fuller believed that the principal substance is leucorotatory beta-oxybutyric acid.

Bacilluria with colon bacilli is more readily cured by this form of treatment than that with a number of other gram-negative bacilli found in infections of the urinary tract. Sometimes more than one organism is present. The most difficult to eradicate is *Paecilus aerogenes*. In such cases ketonurine of a lower pH (from 4.6 to 5.2) may be necessary. As an aid in

increasing the acidity of the urine, the oral administration of ammonium nitrate daily may be used.

In a series of fifty patients with bacilluria of various types so treated, Clark reported successful results in 66 per cent. The effectiveness of ketonuria has been demonstrated by Helmholtz in cases of pyuria in children with anomalies of the urinary tract that have never responded to other treatment. Sterilization of urine may be accomplished in some cases in from five to ten days. Ketonuria should be useful in the preparation of patients for operations on the urinary tract.

The prognosis varies with the type of organism, the extent of the infection, the amount of renal injury and the ability of the patient to produce hyperacid ketonuria. Failure may result from the patient's inability to digest fat or to excrete its products, thus avoiding ketosis. Alkalinization and dilution of ketonuria will each cause the disappearance of its bactericidal properties. The avoidance of excessive fluids is necessary; a normal intake is permissible. The presence of ketosis is quickly demonstrated by adding from eight to ten drops of a 10 per cent solution of ferric chloride to a few cubic centimeters of urine. If diacetic acid is present, a characteristic dark red color will develop.

The ketogenic diet is exceedingly high in fat and low in carbohydrate. In references listed the general scheme for planning such a diet is considered. The details of this diet can be found in a number of books on dietetics. To obtain satisfactory results a quantitative diet is desirable and the services of a dietitian may be required, at least at first. Although a qualitative ketogenic diet may be used later, the patient's complete cooperation is essential. As the body adjusts itself to the diet ketonuria may lessen to some extent and a temporary return to a mixed diet may be indicated. The diet is apparently harmless, but to avoid any consequences from deficiency of vitamin B, such as pellagra or amenorrhea, a teaspoonful of brewers' yeast is given daily. The value of this diet has been confirmed by Band, Dunlop and Dick, and by Fuller, successful results being obtained even in very chronic and intractable urinary infections.

TOXICITY OF PYROGALLOL AND THIOCARBANILIDE

To the Editor—I am desirous of obtaining information concerning the toxicity of pyrogallol and thiocarbanilide and the possible physiologic effects accompanying a more or less frequent contact with these substances. I am particularly interested in these substances as a source of irritation and occupational disease. Please omit name. MD Texas

ANSWER—Pyrogallol (pyrogalllic acid) is a powerful reducing agent. Solimann's Manual of Pharmacology, 1932, contains the following in regard to its physiologic effects:

Locally it is a mild caustic for wounds and mucous membranes; it produces but slight irritation of the intact skin passing into erythemas on continued use. Absorbed into the blood it forms methemoglobin, disrupts the corpuscles and leads to intense acute nephritis. Concentrated solutions acting on blood in vitro (not in the body) produce a peculiar insoluble substance, hemogallol. Fatal poisoning may occur even when the drug is applied to the intact skin and may set in suddenly after it has been used for some time without effects. The symptoms consist in diarrhea and vomiting, chills, prostration, feeble pulse, nephritis with scant dark urine containing blood or hemoglobin derivatives (Neisser 1881), sometimes icterus and glycosuria. The rapid cases show cyanosis, dyspnea, convulsions and collapse.

A case of fatal poisoning in a patient treated with an ointment containing pyrogallol (percentage not known) is reported in the *Pharmaceutical Journal* (London), Sept. 26, 1925, page 396. Pyrogallol is a constituent of some hair dyes; its potential harmfulness when so used is pointed out in a query and minor note in *THE JOURNAL*, July 8, 1922, page 152, and in the paper of H. N. Cole, *The Dermatoses Due to Cosmetics* *THE JOURNAL*, June 14, 1924, page 1909.

Much less information is available with regard to thiocarbanilide. This substance, also known as sulphocarbanilide (*a-b* diphenyl thiourea), is used in the rubber industry. A paper on the health hazards of numerous chemicals used in the rubber industry, including thiocarbanilide, was published by R. S. Quimby in the *Journal of Industrial Hygiene* 1926, page 103. An article by P. A. Davis (*Rubber Age* 1930, p. 305)

states that thiocarbanilide is not poisonous itself, though its decomposition products are toxic.

The query and minor note entitled "Possible Poisoning from Well Known Rubber Curing Accelerators" (*THE JOURNAL*, Sept. 15, 1928, p. 822) discusses the conditions under which thiocarbanilide may produce deleterious results.

A comprehensive classification of the materials used in the rubber industry and their hazards to health was recently published by the National Safety Council, "Compounding Materials Used in the Rubber Industry," Industrial Safety Series, no. 1, Chicago, National Safety Council, 1931.

LIVER GROWN

To the Editor—What is the trouble in the so-called popular remedy known as liver grown in infants after being shaken up by a wagon ride? Please omit name. MD Pennsylvania

ANSWER—The term "liver grown" is an obsolete expression and was formerly used to designate enlargement of the liver. The liver may be enlarged in infants in a variety of conditions such as sepsis or specific infectious diseases, or in congenital syphilis, miliary tuberculosis, malaria and tropical leishmaniasis, echinococcal disease and other parasitic infections. Associated with icterus the liver may be enlarged in congenital atresia of the bile duct, catarrhal and epidemic icterus, familial icterus gravis and congenital hemolytic icterus. Associated with blood diseases is leukemia, severe secondary anemia or von Jaksch pseudoleukemia infantum, the liver may be enlarged as well with lipid metabolic disturbances as Gaucher's disease and Niemann-Pick's lipid histiocytosis. Rarely in an infant a cirrhosis as a portal or Hanot's type, may cause liver enlargement.

Tumors of the liver in infancy are uncommon, though both sarcoma and carcinoma are known to occur. Hemangio-epithelioma, which may involve an extensive area of the liver, may cause a great enlargement of the organ. Thus the liver of an infant may be enlarged from a variety of causes. What etiologic importance may be attached to such a popular malady as "liver grown" in an infant who has been shaken by a wagon ride could hardly be logically deduced.

TREATMENT OF SYPHILIS

To the Editor—On page 731 of *THE JOURNAL* for August 26 there appears a query as to the prophylactic use of arsphenamine in an individual who had been exposed to syphilis from four to five weeks previously. Whether prophylactic arsphenamine is ever justifiable is a debatable point. If it is used it is certainly of no value if given later than forty-eight hours after the suspected exposure. In the situation outlined by your inquirer only two proper courses are open: first to observe the patient at weekly intervals or oftener for the appearance of possible lesions which should be examined promptly in the dark field if and when they occur and at the same time to follow the patient with weekly Wassermann tests for a minimum period of three months. It has been repeatedly demonstrated that under the circumstances outlined by your inquirer infection with syphilis is not inevitable and that some such exposed individuals will escape.

The second alternative is to treat the patient as if he had seronegative primary syphilis, namely with a minimum of nine months of continuous treatment involving at least three courses each of an arsenamine and bismuth. Anything less than this amount of treatment and in particular the four or five prophylactic doses advised in the answer may merely suppress the infection instead of eradicating it, leave the patient open to the possibility of the subsequent development of cardiovascular syphilis or neurosyphilis and certainly should not free either the patient or the physician from anxiety. JOSEPH E. MOORE, MD, Baltimore

COMMENT—The first sentence in the reply was an error, an unwarranted concession to the opinions of others. The rest of the answer, however, is in accord with Dr. Moore's opinion, though less emphatically stated.

TREATMENT OF CANCER

To the Editor—What medication if any, in addition to the use of high voltage roentgen therapy, may be used with some promise of benefit in retarding the growth of inoperable carcinoma? Please omit name and address. MD Wisconsin

ANSWER—X-rays and radium remain the only demonstrated and accepted methods in the treatment of inoperable cancer. The benefit that can be derived from these agents depends on numerous factors, the most important of which are the radio-sensitivity of the tumor and the extent of the disease. For many years intense efforts have been made to develop constitutional remedies for the treatment of these conditions. In general these efforts have failed. Recently there has been some evidence that the internal administration of barium gluconate has effected favorably a growth of inoperable cancer. These results are still new so that their real value awaits confirmation.

HYPERTENSIVE HEART DISEASE WITH
DECOMPENSATION

To the Editor—A man aged 45 came to my office complaining of dyspnea of one year and six months duration. He states that he has had similar attacks of dyspnea in the past but not as frequent as in the last year and a half. The dyspnea is now persistent and becomes worse on exertion. He has to use three pillows at night. He coughs and the expectorations are scanty. On physical examination the following positive conditions were noted. The man was dyspneic and apparently in distress. The left border of the heart was about 2 cm outside the mid clavicular line. The heart otherwise was normal. The pulse was 100. The blood pressure was 230 systolic 160 diastolic. The lungs were resonant but there was diminished breathing in both bases with numerous rales heard both on inspiration and on expiration. The rales on expiration were sonorous. The rest of the physical examination was negative. The urine presented a trace of albumin. The specific gravity was 1.010 (mid-afternoon specimen). The Wassermann reaction was negative. I am now planning a nonprotein nitrogen and a dilution concentration test. Two specimens of sputum were obtained for tuberculosis and also a chest plate. What would you suggest in the line of treatment? Patients with asthmatic bronchitis and bronchiectasis obtain relief by the use of ephedrine sulphate by mouth. Would this be contraindicated in view of the markedly elevated blood pressure? Would syrup of calceosol be contraindicated? I understand that calceosol is a phenol derivative and one should think of the effect on the renal function. Any suggestion will be helpful. This man has worked hard all his life. Please omit name.

M D Massachusetts

ANSWER—It would seem that the primary diagnosis in this case must be hypertensive heart disease with decompensation. In a patient of this age with the heart and urinary conditions as mentioned, a diagnosis of so called malignant hypertension is suggested particularly in view of the negative Wassermann reaction. The nephrosclerotic element may be determined by the dilution concentration test and the nitrogen retention and an examination of the eyegrounds would be of value.

Assuming this diagnosis to be correct, the cough and dyspnea would be largely caused by the pulmonary congestion, and this should be attacked by the use of the theobromine compounds or the acid base salts with, perhaps, an occasional mercurial diuretic. Any of the theobromine compounds are satisfactory, but theobromine calcium salicylate or the alkaloidal theobromine is probably the least nauseating. Ammonium nitrate or ammonium chloride are the acid base salts of choice.

Ephedrine sulphate would probably be no more effective than the remedies mentioned and there is evidence to suggest that a damaged heart does not well tolerate this drug. Syrup of calceosol is not contraindicated but its effectiveness here is extremely doubtful.

BURNING SENSATIONS IN LIMBS AFTER HEMIPLEGIA

To the Editor—Two years ago a man aged 50 suffered a hemiplegia on the right side which was treated with favorable results. At present he suffers from hot sensations of the upper right extremity. He describes the feeling as that of fire starting from his right fingers up to his right shoulder. This feeling makes him uncomfortable and sometimes interferes with sleep. It varies in intensity with intervening periods of relief. My examination disclosed a slight degree of mental unbalance and slurring speech though he answers questions intelligently. He is depressed and worried, reports his answers and seems to be melancholic. The Wassermann reaction is negative. The pupillary reaction is normal. The knee jerk is increased. White and red blood counts are normal. The basal metabolism rate is normal. No spinal puncture has been made. The blood pressure is 160 systolic 85 diastolic. The patient can make use of the previously paralyzed limbs. Electrical treatments and iodides have been given without any relief from the hot sensation or hyperesthesia. Kindly suggest treatment that will benefit this patient's abnormal sensation. Please omit name and address.

M D California

ANSWER—When a patient with partial hemiplegia complains of burning sensations of the kind here described it is practically certain that his brain lesion involves the optic thalamus. Treatment is unsatisfactory but in many cases the disagreeable sensations gradually become less troublesome. Hydrotherapy and electricity in some form may be useful and a combination of a bromide and tincture of hyoscyamus may be of some symptomatic value.

HYPERESTHESIA IN DIABETES—HYPERTENSION

To the Editor—1. What medication would be of service in the treatment of the hyperesthesia accompanying diabetes mellitus complicated by a slowly developing Parkinsonism? 2. Might the persistent finding of a systolic blood pressure of 135 in an otherwise healthy man of 22 indicate hypertensive disease in later life? Will you please omit name.

M D New York

ANSWER—1. The answer to this question would depend on the state of the diabetes. If the hyperesthesia was due to persistent glycosuria and hyperglycemia, dietetic measures along the usual lines of the treatment of diabetes are indicated. If on the other hand the hyperesthesia is part of the Parkinsonian syndrome it might be wise to employ some doses of scopolamine. The probabilities are that the hyperesthesia is due to diabetes.

2. A persistent systolic blood pressure of 135 in a man aged 22, indicates that for the time being at least the patient has a tendency to hypertensive disease. Whether this means the development of hypertension later in life is another story, depending a great deal on what the cause of the present status is. Cases are known of hypertension occurring in young adults which completely disappear later in life. It would seem that the ultimate outcome would depend to a certain extent at least on heredity and the family history of the individual. If he belongs to a hypertensive family the outlook would be more grave than if this is an isolated instance with a normal family history.

SENSITIVITY TO EUPHORBIA

To the Editor—At present we have three patients suffering with a dermatitis produced by *Euphorbia marginata*, a plant commonly known as mountain snow. We were unable to find reference in the literature to any skin manifestation produced by this plant. Can you give any information regarding such a dermatitis?

M D Wisconsin

ANSWER—*Euphorbia* is a large genus of which more than a hundred species are found in this country, some cultivated, the wild ones partly indigenous, partly imported. Authorities state that the juice of all of them is irritating to the skin. Known as spurge, parts of some varieties were formerly used as emetics but have been discarded as too irritating. The gum resin of one *Euphorbia resinifera* from Morocco, was incorporated in plasters and used for prolonging suppuration. Quacks used the juice of these plants for the treatment of warts and freckles. Erysipelatous pustular and phlegmonous dermatitis even gangrene, has been produced by the juices of these plants.

It is therefore no surprise to find seven species, among them *Euphorbia marginata* listed in Weber's list of skin irritants (*Arch Dermat & Syph* 21 763 [May] 1930). Ten tropical species are listed.

SPINA BIFIDA OCCULTA

To the Editor—I delivered a primipara at full term. Delivery was spontaneous. On the third day post partum the baby suddenly became cyanotic. With carbogen the cyanosis cleared. A roentgenogram was taken to determine atelectasis. This proved negative but coincidentally it was noticed that only the right half of the second lumbar vertebra was developed. The left was missing and distal to this there was an angulation of the spine of about 30 degrees. Will nature fill in the gap? How soon should treatment begin if necessary? Where can I find reports of similar cases in the newborn? Kindly omit name.

M D New York

ANSWER—The condition here described is probably a spina bifida occulta. As there is no mention of paralysis of the lower extremities or loss of sphincter control, the spinal cord is probably normally developed. A defect in the bony structure of the lumbar vertebra may have to be remedied by orthopedic measures at a later stage of the child's development, if a considerable degree of kyphosis or spinal deformity persists. The eventual outcome, of course, is dependent on the extent of the bony defect.

The following articles may be of help in this case.

IRREGULAR MENSTRUATION

To the Editor—A woman aged 23 has menstruated only two or three times a year since the menses appeared at the age of 14. These periods last only one day and there is a very small flow. She also has a very obstinate case of constipation and colitis and is slightly underweight. Her condition otherwise is excellent. She has been examined by several competent gynecologists all of whom report no pathologic changes. Please advise me about treating this case (with preparations similar to aminotin, antimin or progynon). Please omit name and address.

M D Iowa

ANSWER—The fact that a woman menstruates only two or three times a year does not necessarily indicate that she is ill. She is not entirely normal because normal young women menstruate at much more frequent intervals usually twenty-eight days apart. She may be further abnormal in that most likely ovulation occurs only two or three times a year and therefore her chances of becoming pregnant are less than those of other women. However this conclusion does not necessarily follow because ovulation may occur without menstruation just as menstruation may take place without ovulation. Therefore there is no need to give this woman any special treatment.

other than measures to overcome her constipation and colitis. Amniotin, antuitrin and progynon are expensive preparations which must be given over long periods of time. They do not always produce uterine bleeding and even when they do the flow of blood is not always the same as true menstruation. There is really nothing to be gained by making a woman bleed at more or less regular intervals by means of estrogenic preparations except that she may feel better psychically. Furthermore, these preparations should be used with great caution because harm may result. In certain animals, injection of these substances has resulted in sclerosis of the ovaries, diminution in size of the anterior pituitary, hypertrophy of the posterior pituitary, hyperplasia of the thyroid and other changes.

HYPERPLASIA OF PROSTATE

To the Editor—A man aged 65 in good health weighing 170 pounds (77 kg.) has never used alcohol. He is well preserved and not senile. He had syphilis forty-four years ago and has had mercuric rubs and iodides at various intervals for a number of years. He had gonorrhea twenty-one years ago but did not have proper treatment. He has had prostaticitis and cystitis for fourteen years and complains of a burning sensation in the prostate and urethra which is worse when he voids. I have been treating him for a year with massage, irrigation with potassium permanganate, diathermy and experimental gland therapy. The gland was enlarged to 50 mm. or more and I have reduced it nearly half. I have catheterized him several times just after he has voided and found a drachm or a drachm and a half (from 4 to 6 cc.) of urine. He objects to cystoscopy or any operation. The urine has had blood in it three different times but is clear most of the time. Once in a while it may be a little cloudy. The urine is free from albumin and sugar; the specific gravity is 1.020. I have never given instillations of silver nitrate or urinary antiseptics by mouth. I have several cases that are similar. If the patient voids every hour the amount will be from 1 to 1½ ounces (from 30 to 45 cc.) two hours 2½ ounces (75 cc.) three hours from 3½ to 4 ounces (from 100 to 120 cc.). What am I going to do with these patients that refuse operations? Please omit name.

M D Colorado

ANSWER—The patient under consideration probably has a prostatic hyperplasia with additional inflammatory changes. An exact diagnosis, especially tracing the source of the occasional hematuria, could not be established except by cystoscopy. When a patient refuses any instrumentation, some valuable information may be gained by making a cystogram. As a contrast fluid for filling the bladder before roentgenography a nonirritating solution should be chosen such as 10 per cent neosilol solution or any of the compounds used in intravenous urography. In instances in which hyperplasia and inflammatory changes are coexistent and surgical intervention is not to be considered one is obliged to resort to methods that furnish a fair chance for the relief of the subjective symptoms. Fractional roentgen treatments combined with protein therapy are apt to answer this demand. In oldish persons whose heart might not withstand the use of foreign protein, autohemotherapy should be given the preference.

AMBLYOPIA IN PREGNANCY

To the Editor—Is it possible to get an acute toxic amblyopia from pregnancy without evidence of an acute nephritis?

M H Newton M D Little Falls N Y

ANSWER—Pregnancy per se does not lead to an acute toxic amblyopia. As the query implies in practically all cases of amblyopia during gestation there is an associated nephritis or toxemia. Of course, amblyopia may appear during pregnancy after excessive use of wood alcohol or tobacco just as it may occur in nonpregnant individuals, but this has nothing to do with the pregnancy itself.

PIGMENTATION OVER TIBIA

To the Editor—Can you suggest anything that might remove the copper colored spots traumatic which so often happens over the flat surface of the tibia? Please omit name.

M D California

ANSWER—If small, they may be removed surgically, but this is seldom advisable. No peeling treatment is apt to succeed. Hemorrhage occurs readily in this region in many people and any irritation might increase it, thereby increasing the pigmentation.

EFFECT OF IODIDES ON WASSERMANN TEST

To the Editor—During the administration of iodides in the treatment of syphilis is there an iodine saturation effect on the blood lipoids that affects the blood Wassermann test?

CHARLES C HINTON M D Macon Ga

ANSWER—No. The iodides do not affect the Wassermann test in any way.

Wisconsin June Report

Dr Robert E Flynn secretary Wisconsin State Board of Medical Examiners reports the written and practical examination held in Milwaukee June 27-30, 1933. The examination covered 19 subjects and included 100 questions. An average of 75 per cent was required to pass. One hundred and six candidates were examined 99 of whom passed 3 failed and 4 were conditioned. Twenty-five candidates were licensed by reciprocity and 2 by endorsement. The following colleges were represented:

Book Notices

The Operative Story of Cleft Palate. By George Morris Dorrance. MD. F.A.C.S. Professor of Maxillo-facial Surgery, the Thomas W. Evans Museum and Dental Institute School of Dentistry, University of Pennsylvania. Assisted by Inayat Shihry, DDS. Cloth. 144 pp. \$6.00. Pp. 14 with 31 illustrations. Philadelphia & London: W. B. Saunders Company, 1933.

A complete history of the operative procedures for cleft palate is given; they are copiously illustrated and more than 4000 references are included. In the first chapter on the historiography of cleft palate, Dorrance says: "The operative story of cleft palate is by no means an easy task to narrate despite the fact that of all the procedures in surgery, the operation is about the only one which can be traced to its origin with any degree of accuracy. No one surgeon can have complete claim to any operative procedure since each method resulted from the experiences of many contributors whose efforts are interdependent. Dorrance has undoubtedly left little or nothing to be covered in the tracing of cleft palate surgery and after studying his book one would find that the field for new ideas is extremely limited. In the chapter on conclusions there is an admirable appraisal of the general methods of procedure with the author's own ideas of their advantages and disadvantages. He leads up strongly to his present method of palate closure and to his push-back operation for short velums and partial clefts and a modification of it for complete clefts. The recent work of Logan on the position of the tooth buds is omitted but since Dorrance's procedure of closure is done preferably after 5 years of age the buds will be out of the way of closure. To the beginner

this book might be an invaluable aid if he accepted all of Dorrance's views and investigated further from this point. To the experienced operator the book will be invaluable for settling many details of priority, for help in evaluating procedures, and for reference to Dorrance's methods, to all who are interested in the work the book will prove a source of enjoyment and enlightenment.

Atlas der Erkrankungen der oberen Luftwege mit besonderer Berücksichtigung des Epipharynx. Von Dr. Siegfried Cräff, leitender Oberarzt am pathologischen Institut des allgemeinen Krankenhauses Barmbeek in Hamburg. II. Lieferung. Paper. Price 20 marks. Pp. 86 with 71 illustrations. Leipzig: Curt Habitzsch, 1933.

This is the second part of an atlas portraying the diseases of the upper respiratory tract with particular reference to the epipharynx. As stated in the review of part I, the author has developed a method of removing post mortem the tissues of the nasopharynx, mesopharynx and hypopharynx *en masse*, so as to demonstrate easily the pathologic processes present. Nineteen cases are dealt with. Instances of normal anatomy in premature infants and the very young are photographically demonstrated. Among other conditions treated are hyperplasia of Waldeyer's ring, lymphatic leukemia widespread diphtheria of the pharynx and nasal cavities, various tuberculous processes of the pharynx and larynx, thrush of the upper respiratory passages, and one instance of congenital abnormality of development of the palate. The photography of these various specimens leaves little to be desired. The few colored ones among them are well done. The atlas, when published complete, should be a valuable source of information concerning the diseases of this part of the body.

The Peninsula of Yucatan. Medical, Biological, Meteorological and Sociological Studies. By George Cheever Shattuck, MD, Assistant Professor of Tropical Medicine, Harvard University Medical School. In collaboration with Joseph C. Bequaert, PhD, and others. Carnegie Institution of Washington Publication No. 431. Paper. Pp. 576 with 98 illustrations. Washington, D. C.: Carnegie Institution of Washington, 1933.

This monograph gives the findings of the first, second and third Yucatan medical expeditions, which were organized at the instigation of the Carnegie Institution of Washington by the Department of Tropical Medicine of Harvard University and took the field in 1929, 1930 and 1931. The object of the first expedition was a preliminary survey of disease in Yucatan; that of the second to supplement the preliminary survey and to throw light on questions relating to syphilis and basal metabolism among Mayan Indians, and that of the third primarily the distribution of malaria and amebic dysentery during the rainy season.

Part I, comprising 99 pages by Shattuck, Redfield and MacKay, deals with general and miscellaneous information about Yucatan. Chapter I gives a background dealing with such subjects as geography, flora, fauna, geology and physiography; chapter II gives an outline of the history of the peninsula, both ancient and modern; chapter III, a wealth of anthropological data; chapter IV, an outline of the civil government and official health organization; and chapter V, a description of some important communities.

Part II, comprising 350 pages by Shattuck with contributions by various collaborators, is entitled "Medical Surveys and Other Data." Chapters VI, VII and VIII give medical surveys of different localities; chapter IX, an account of life in the forests of Quintana Roo; chapter X, a description of the Maya of Campeche, Guatemala, British Honduras and Chiapas; chapter XI, bacteriologic studies; chapter XII, animal parasites of man and animals; chapter XIII, syphilis; chapter XIV, blood picture, blood pressure and basal metabolism; chapter XV, leishmaniasis, trachoma and folliculosis; chapter XVI, epidemic diseases; chapter XVII, malaria, dysentery and certain other infectious diseases; chapter XVIII, miscellaneous diseases; chapter XIX, vital statistics; chapter XX, the climate of the peninsula; and chapter XXI, general considerations on disease, health and economic problems.

Part III, comprising 70 pages by Saunders in collaboration with Cornell, supplements part II and deals with further medical surveys (chapter XXII), malaria and other important infections (chapter XXIII), amebiasis (chapter XXIV), blood pressure (chapter XXV) and blood picture (chapter XXVI).

Part IV, comprising 76 pages, by Bequeret in collaboration with Clench, consists of various contributions to the natural history of the peninsula. There are botanic notes (chapter XXVII), descriptions of nonmarine mollusks (chapter XXVIII), entomologic contributions (chapter XXIX), and two appendices on reptiles and parasites of reptiles.

Throughout there are a wealth and variety of detail that preclude any detailed review. Among the many interesting facts brought out may be mentioned the following. An examination of 1,362 stools from 854 persons revealed 19.5 per cent infected with *Endamoeba histolytica* and allowing for the limitations of the method used it is estimated that the actual incidence of infection is about 40 per cent. In the same group 3.3 per cent showed evidence of active amebic dysentery and it is believed that a large proportion of clinical dysentery with blood and mucus in the stools is due to *E. histolytica*. Malaria is scarce, and of 2,198 blood smears only 48 were positive in thin film. Undoubtedly a large factor in this low incidence is the great scarcity of anophelines. Clinical evidences of syphilis in the Maya and Mestizos is practically nil although Kahn tests on 576 persons showed 57 per cent positive. Systolic pressures for the Maya are definitely lower than for Americans.

The report as a whole makes fascinating reading and although primarily medical no pains have been spared to bring in the relevant historical, sociological and economic backgrounds. Throughout the data have been compiled and discussed with reference to similar data from other localities. The volume is well illustrated and there is a short bibliography appended to each chapter. There is no general index.

Cancer and Other Chronic Diseases in Massachusetts. By George H. Bigelow, M.D., Dr. P.H., Commissioner Massachusetts Department of Public Health, and Herbert J. Lombard, M.D., M.P.H., Director, Division of Adult Hygiene, Massachusetts Department of Public Health. Cloth. Price \$4. 1 p. 350 with 11 illustrations. Boston & New York: Houghton Mifflin Company, 1933.

In this comprehensive volume the authors discuss the broad problem of chronic disease and point out that the aim of any serious social problem is a conscious and rational control of sickness and death. In fifty years the death rate in Massachusetts has dropped 25 per cent while the birth rate has correspondingly fallen 30 per cent, indicating an aging of the population. The increase in cancer is not apparent but real. Fifty years ago chronic diseases made up one third of the deaths in Massachusetts whereas today they constitute two thirds of the deaths. According to the authors the medical approach to chronic disease has five aspects: (1) prevention, (2) early diagnosis, (3) cure, (4) alleviation and (5) terminal care. Concerning terminal care, the authors advise against segregation of the dying and point out that few institutions can keep their good names with a death rate over 30 per cent. These individuals should be cared for in small groups near their own homes. In Massachusetts, heart disease furnishes about 20 per cent of all deaths, cancer, 10 per cent. Rheumatism causes fewer deaths but greater disability than heart disease. The average untreated patient suffering from cancer lives two years, heart disease from seven to nine years, rheumatism, fourteen years or longer.

Diagnostic cancer clinics under government stimulation began in Massachusetts in December, 1926. At present twelve clinics are operating in fifteen cities. The clinics were organized by the local medical societies in cooperation with the Massachusetts Department of Public Health. The organization and activities of the Pondville Hospital are described. A chapter on statistical studies on cancer in Massachusetts presents interesting figures. The problem of social service in relation to cancer is discussed by Eleanor Kelly, and a chapter on education is presented by Mary Lakeman.

The authors' names are already well known in public health activities, particularly in the field of cancer. Those interested in the problem of chronic disease will welcome this volume. Aside from the valuable statistical information presented the method of approach and technique of execution of these problems are of extreme interest. The results attained are of such significance that they must form the basis of similar programs in other localities. The data are presented in such attractive style as to render a usually tiresome statistical report highly

entertaining reading. The book should appeal to a variety of individuals—laymen, physicians, hospital administrators, social service workers and public health officials—alike. It is a welcome and important addition to the medical library.

La phrénécotomie. Par L. Barard, professeur de clinique chirurgicale à la Faculté de médecine de Lyon. F. Dumarest, médecin en chef du Sanatorium Mangliat à Hauteville, et Desjardes, chirurgien des hôpitaux de Lyon. 1 paper. Price 30 francs. 1 p. 113 with 19 figures and 17 plates. Paris: Masson & Co. 1933.

It is significant that surgical interruption of the phrenic nerve for pulmonary tuberculosis has attained sufficient importance to stimulate the production of a volume devoted to the subject. The opinions expressed in this book have the virtue of being neither too enthusiastic nor unduly pessimistic. Emphasis is properly placed on the fact that phrenic paralysis produces its best results in relatively early and restricted lesions that are fibrotic and retractile rather than pneumonic in character. The authors have stressed the selective action of the rise and paralysis of the hemidiaphragm with the resulting rest and relaxation of the tuberculous lesions, whether they are in the upper or the lower lung. The chapters on anatomy and physiology have been painstakingly prepared. The volume has a number of major defects that render it unsuitable for recommendation as an authoritative guide. It is apparently the conclusion of the authors that induced pneumothorax should virtually always be tried before phrenic paralysis which, they feel, should be reserved for cases in which pneumothorax is clinically unsatisfactory or to supplement a thoracoplasty or extrapleural pneumonolysis. It is radical practice first to institute a pneumothorax that needs to be maintained for at least one, two or three years, for limited torpid lesions which include a small cavity which a phrenic paralysis has an excellent chance of healing. One of the principal objections of the authors to the initial use of phrenic paralysis is that permanence of the paralysis is uncertain and that if diaphragmatic motion returns a good primary clinical result will be seriously jeopardized. As return of motion is usually due to faulty operative technique, it is avoidable. Incidentally, a cutaneous incision of from 6 to 7 cm. is unnecessary and disfiguring. Temporary paralysis of the phrenic nerve for approximately six months which is obtained by crushing the main phrenic nerve stem and resecting all accessory roots, has greatly extended the usefulness of phrenic surgery in phthisis and is the most important advance that has been made since Goetze and Felix improved the operative technique for permanent paralysis eleven years ago. If a six months paralysis proves to be clinically satisfactory for a given case it may easily be made permanent by another operation but if the clinical result is unsatisfactory by the time diaphragmatic motion returns the patient will not be deprived of this function for life, this is especially important if an upper stage thoracoplasty or extrapleural pneumonolysis then needs to be performed in the presence of bilateral lesions. The authors however do not recommend temporary paralysis because they have found with their operative technique that the duration of the paralysis varies uncontrollably between several weeks and several years. It is unfortunate that more of the opinions expressed by the authors are not based on exact statistical knowledge of their own results. Because many of their first treated patients have been lost track of the authors have not undertaken to present any of their statistics although they have used phrenic nerve interruption for more than 700 patients. Satisfactory roentgenograms of seven cases are reproduced.

The Technic of Local Anesthesia. By Arthur E. Hertzler, A.M., M.D., Ph.D., Professor of Surgery in the University of Kansas. Fifth edition. Cloth. Price \$5. Pp. 292 with 148 illustrations. St. Louis: The C.V. Mosby Company, 1933.

This edition following the fourth in rapid succession, is an eloquent testimony of the usefulness and popularity of Hertzler's monograph. A concise chapter on spinal anesthesia has been added by Dr. Axel E. Spelman and another on intravenous amylal anesthesia by Dr. Raymond F. Gard. This book is truly written with great simplicity advocating methods of infiltration whenever possible. The author properly points out that while complicated nerve blocks may be effective in the hands of experts they do not serve the needs of the average surgeon. The author's vast surgical experience and thorough

Knowledge of pathology permeate the entire volume and are a refreshing contrast to some contributions on the same subject by pure anesthetists. One must, however, take issue with the persistent advocacy of quinine solutions to prolong the duration of anesthesia. While the author's skill may have prevented lasting indurations and sloughs, the general use of this drug must be condemned. This is true also of the use of sterile water as a solvent for procaine. Physiologic solution of sodium chloride is certainly available wherever major or minor surgery is being done and insures an isotonic solution. The author's advice that solutions should be prepared by the surgeon himself just prior to operation is certainly sound. Printing and illustrations are most satisfactory. Dr. Hertzler has added one more excellent treatise on this subject.

Stoke Park Monographs on Mental Deficiency and Other Problems of the Human Brain and Mind. No. 1. The Burden Memorial Volume Dedicated to the Memory of the Late Reverend Harold Nelson Burden Foulmer and First Warden of the Incorporation of National Institutions for Persons Requiring Care and Control. Edited on Behalf of the Medical and Consultant Staff of Stoke Park Colony, Stapleton, Bristol. By Richard J. A. Berry, M.D., F.R.C.S., F.R.S.E., Director of Medical Service. Cloth. Price 10/6. Pp. 249 with 89 illustrations. London: Macmillan & Company Ltd. 1933.

This volume consists of seventeen articles by members of the attending and visiting staffs of the Stoke Park Colony, an institution taking care of 2,000 mental defectives and especially endowed and equipped for research work. Not the least interesting is the brief biography of Rev. Harold Nelson Burden, a man of rare capacities, having excelled at the same time as a clergyman and missionary, as an organizer and administrator, and as a director or at least instigator, of research. All aspects of mental deficiency are discussed including the gross and minute brain changes and neurologic symptoms. There are many excellent illustrations of unusual conditions, perhaps most striking being some of a patient with the Klippel-Feil syndrome (p. 201).

Fractures. By Paul B. Magnuson, M.D., Associate Professor of Surgery, Northwestern University Medical School, Chicago. Cloth. Price \$2. Pp. 466 with 317 illustrations. Philadelphia: J. B. Lippincott Company. 1933.

The author of this book has had a large experience in the treatment of fractures and other industrial conditions. He has written a book to meet the needs of the general practitioner and has attempted to simplify methods of treatment. He approaches the problem of fractures from the standpoint of anatomy and physiology. He states that if the direction and amount of force that cause a fracture plus the muscle pull that maintains it in a position of deformity are clearly understood, and certain fundamentals in the mechanics and reduction are recognized, the surgeon's ingenuity can be relied on to meet the requirements of the individual case. The author has drawn freely from several of his colleagues, notably Potter, Case, Davis and Coulter. The page on fundamentals is good. One of the noteworthy features of the book is the excellent line drawings by Shepard. Some of the roentgenograms do not teach the lessons that are intended, especially figures 149, 154, 172, 182, 194, 277, 278 or 286. Figure 182 is no credit to the book and the publishers. The author's operation which is a modification of the Whitman and Brackett hip reconstruction, is given in excellent style and beautifully illustrated. Figure 100 is a fine illustration of what is known as Monteggia's lesion. All in all this book can be considered a handy volume for the general practitioner.

Biographisches Lexikon der hervorragenden Ärzte der letzten fünfzig Jahre. Herausgegeben von I. Fischer, Privatdozent an der Universität Wien. Zugleich Fortsetzung des Biographischen Lexikons der hervorragenden Ärzte aller Zeiten und Völker. Lieferungen I-11 (2 Bände). Paper. Price 54 marks per set. Pp. 1711 with 160 illustrations. Berlin and Vienna: Urban & Schwarzenberg. 1927/1937.

This volume is devoted to brief biographies of leading physicians of the last fifty years. The American editor whom the German editor thanks for cooperation in providing names of American physicians was Dr. Fielding Garrison. The book contains some pictures of the Americans selected for illustration being Drs. John Shaw Billings, William Crawford Gorgas, J. C. Hemmeter, Jacques Loeb and William Osler. Most of the biographies are short, the average being approximately ten lines, but some occupy from twenty-five to fifty. The work

is an exceedingly useful reference work to the prominent names in medical science. No doubt there are serious omissions, as inevitably must occur when a work is selective, as is this one, but for what it contains it is accurate and dependable.

Das Röntgenraumbild. Von Dr. Werner Teschendorf, Chefarzt des Strahlentherapie-Instituts der Allg. Ortskrankenkasse Köln und Dr. Hans Köhnle, Röntgenologe der Inneren Klinik der Medizinischen Akademie Düsseldorf. Paper. Price 9 marks. Pp. 173 with 126 illustrations. Berlin: Urban & Schwarzenberg. 1933.

This monograph also appears under the title "Die Röntgenstereoskopie" in Abderhalden, *Handbuch der biologischen Arbeitsmethoden*, Abt. II, Teil 3 (Lfg. 408). The importance of the stereogram in roentgen diagnosis cannot be overestimated. Unfortunately, most works on stereoscopy are too technical, too elementary or too specialized on some variety of apparatus or on some procedure to be of general interest. The present monograph, therefore, tends to fill a wide gap in roentgenologic literature. In it the authors discuss the optical fundamentals, both theoretical and technical, of stereovision, especially in its roentgenologic aspects. Representative types of apparatus are discussed in some detail to emphasize the structural and stereographic peculiarities of the roentgen stereoscope in general. The most important sources of error are outlined, important hints are given as to how to utilize roentgen stereoscopy to its greatest advantage, and lines of future development are indicated. An extensive bibliography of twenty-two pages closes the work. This book should be studied by all roentgenologists because of the great importance of its succinct contents. This would be facilitated by a more complete index of the subject matter.

Meningite aguda linfocitária benigna. Idéias gerais sobre as meningocelulomielites por vírus neurotróficos. Por Dr. Fernando de Oliveira Bastos. Tese de doutoramento apresentada à Faculdade de medicina de São Paulo e aprovada com grande distinção. Grau 10. Trabalho da clínica psiquiátrica e neurológica (serviço do Prof. Enjolras Vampre). Paper. Pp. 112. São Paulo: Faculdade de medicina de São Paulo. 1933.

This doctorate thesis deals with so-called benign acute lymphocytic meningitis, a condition that has been receiving some attention in several European countries during the last ten years. It has sometimes coincided with small epidemics of poliomyelitis and encephalitis and may then have been a meningeal form of one of these diseases. The existence of this benign disorder should be borne in mind in the differential diagnosis of lymphocytic tuberculous meningitis. Nine cases are related in detail. The literature is thoroughly sifted, and a bibliography of 199 numbers is appended.

Diagnostic et traitement du kala azar méditerranéen de l'enfant et de l'adulte. Par M. D. Elsalitz, licencié en sciences. Preface du Dr. Fernand Bezançon. Paper. Price 17 francs. Pp. 110 with 18 illustrations. Paris: Masson & Cie. 1933.

After calling attention to the growing importance of this disease to physicians in the French Mediterranean littoral, the author endeavors to bring together the information published in recent years bearing especially on diagnosis and treatment of the disease as it occurs in children and in adults. The clinical characters of the infection receiving attention are the incubation period and prodromal symptoms, the course of the temperature, splenomegaly and hepatomegaly, anemia, cutaneous symptoms, and the minor signs such as digestive and respiratory disturbance, and edema. The serologic tests discussed are the formal-gel test, Chopra's urea stabamine test, and Brahmachari's serum globulin test. Parasitologically the Leishman-Donovan bodies may be demonstrated directly or the leptomonad forms resulting from them may be grown culturally. The direct demonstration of Leishman-Donovan bodies is made through splenic or hepatic puncture. The emphasis is placed on splenic puncture with a mere mention of hepatic puncture, although the former is known to be decidedly more dangerous. No mention is made of the effectiveness of hepatic puncture combined with cultivation of the material obtained by puncture. Blood culture on *N.N.* medium is thought to be as accurate as splenic or hepatic puncture when it is properly carried out, and this method does not involve the dangers attached to puncture. Chapters are given on treatment with antimony and potassium tartrate, its results and the accidents from and contraindications to its use. A brief chapter is given on the surgical treatment of the disease. The bibliography is incomplete, references only to French articles being given.

Medicolegal

Liability of Hospital for Negligence of Nurse Hypodermoclysis—An appendectomy was performed on one of the appellees, at the defendant's hospital. While the patient was still unconscious one of the defendant's nurses performed a hypodermoclysis, injecting the solution into the patient's breasts. Attributing to this injection injuries to her breasts and to her health generally, the patient and her husband sued the defendant. Judgment was given in their favor, and the defendant owner of the hospital appealed to the Supreme Court of Florida.

The fact that the nurse performed the hypodermoclysis was not disputed. She admitted that she noticed ill effects from it before she had injected more than 50 cc of the solution, the tissues were not properly absorbing the injection. But she did not stop, nor did she call a physician to her aid. She continued until she had injected about 650 cc of the solution into the breasts of her unconscious patient. As a result, the patient's breasts were scarred, defaced and practically destroyed, and she suffered ill health.

To care for the unconscious patient, said the Supreme Court, was admittedly a part of the nurse's duty. That duty included the correlated duty of not continuing the hypodermoclysis after it was evident that it was affecting the patient badly. This correlated duty was neglected when the nurse, after noticing the bad effect of the operation she was performing, neither discontinued it nor called in medical aid. The evidence showed that the hypodermic needles used in performing a hypodermoclysis are usually handled by or under the direct supervision, observation and direction of a physician. Regardless of the nurse's competence and good faith and regardless of the care used by the hospital in employing her, the hospital, said the Supreme Court, is legally liable for the results of her breach of duty. The duty of the hospital is to nurse and care for its unconscious patients properly, not to subject them to personal injuries by continuing a course of treatment that is having an obviously unusual and deleterious effect. The testimony of the nurse was sufficient to sustain the verdict.

The defendant's contention that the reaction of the patient to the hypodermoclysis was caused by an idiosyncrasy in her physical makeup said the court was passed on by the jury. The jury found that even if the patient was peculiarly susceptible to injury by the hypodermoclysis, the nurse persisted in the operation after she was aware of its ill results. A person who is injured by the negligence of another is entitled to recovery even though the injured person is by reason of a preexisting disease condition, more susceptible to injury than is an ordinary person. Certainly a person is not bound to be free from all complications in order to be entitled to recover damages for an injury he sustains through the negligence of another.

It was no defense for the hospital, said the court to claim that because its business is not conducted for gain or profit although charges are made for rooms and for nursing service therein, it is exempt from any and all duties toward the patient except that of using due care in the selection of suitable and competent attendants. The owner and proprietor of a hospital is liable for the positive negligent infliction of injury on a patient by an employee nurse, regardless of whether due care was or was not used in the selection of the nurse.

The judgment of the court below in favor of the injured patient and her husband was affirmed.—*Parrish v Clark (Fla)* 145 So 848

Compulsory Sterilization Statute Unconstitutional Provision for Notice and Hearing Required—Mary Brewer the plaintiff, was 27 years old. She went to work when she was 10 years old married early, and was the mother of five children. There was nothing in the record impugning Mrs. Brewer's character. When her husband worked, he drank and gambled and did not put his money into proper channels. His family often went hungry. Some one whose identity the decision does not disclose, thought that Mrs. Brewer should be prevented from giving birth to more children. Proceedings

were therefore instituted against her, under a North Carolina statute (Michie's N. C. Code of 1931, sections 2304 (i) and 2304 (j)) authorizing the sterilization of any mentally defective or feebleminded resident of the state, not an inmate of any public institution, on the petition of his or her next of kin or legal guardian. A hearing was held before the superior court of Forsyth county and a jury, April 29, 1932. Mrs. Brewer was adjudged incompetent to manage her affairs and a guardian was appointed, and on the same day the guardian requested the board of commissioners of the county to have Mrs. Brewer sterilized. Apparently no notice of the proceeding looking toward her sterilization was served on her and she was given no opportunity to be heard. The board of commissioners nevertheless authorized and ordered Dr. A. DeT. Volk to perform the operation. Mrs. Brewer thereupon sought a restraining order to prevent Dr. Volk from operating. The superior court of Forsyth county held that the statute under which the sterilization of Mrs. Brewer had been ordered was invalid and unconstitutional in that it failed to provide for giving proper notice of the operation and an opportunity to present witnesses and to be heard. It therefore enjoined Dr. Volk and the other defendants named in the petition from performing the proposed operation. The defendants thereupon appealed to the Supreme Court of North Carolina.

In property rights, said the Supreme Court, due process requires a forum, with notice and a hearing. It goes without saying that the same must apply to human rights. The North Carolina eugenic sterilization act makes no provision for notice and hearing for the person whom it is proposed to sterilize. It therefore impinges the due process clause of the constitution. The judgment of the court below, permanently enjoining the proposed sterilizing operation was therefore affirmed.—*Brewer v Volk (N. C.)* 167 S. L. 638

Wills Delusions and Testamentary Capacity—Monomania sometimes designated paranoia, says the Supreme Court of Florida, has reference to a craze or mania for a single object or class of objects. The victim of it may be perfectly sane as to all other objects. As is the case with an insane delusion monomania presupposes mental disease. An insane delusion is not proved by evidence of undue prejudice, if that prejudice is based on any kind of reasoning. An insane delusion has been defined as a spontaneous conception and acceptance as a fact, of that which has no real existence except in imagination. The conception must be persistently adhered to against all evidence and reason. It has also been defined as a conception originating spontaneously in the mind without evidence of any kind to support it which can be accounted for on no reasonable hypothesis has no foundation in reality and springs from a diseased or morbid condition of the mind. In the present case the probate judge had held that because the testator spoke of his son in an indecent and lewd manner he was so unnatural as to be motivated by an insane delusion. But chastity of diction said the Supreme Court of Florida, is not a determinant of testamentary capacity. There is a vast difference between a vulgar or a depraved mind and a diseased mind. The latter is characterized by decay and spontaneous conceptions without any basis for them in fact or reason, while the former may be strong and vigorous.—*Hooper v Stokes (Fla)* 145 So 855

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Measuring Blood Flow in Man—Robb and Weiss injected intravenously sodium cyanide in amounts sufficient to stimulate respiration in thirty-five normal persons. The injections were made rapidly from a graduated 1 cc Luer syringe. The optimal dose of cyanide varied with the weight of the subject and with the site of injection. The average optimal dose for injection into the antecubital vein was 7 mg, corresponding to 0.35 cc of a 2 per cent solution of sodium cyanide or 0.11 mg per kilogram of body weight. With jugular vein injections a comparable effect was obtained with approximately two thirds of the antecubital dose. For foot injection one and one half times the antecubital dose were required. The time elapsing between injection and the occurrence of increased respiration corresponded closely to the circulation time. The authors used the external jugular vein of the neck to measure the pulmonary circulation time and the antecubital vein of the forearm or a superficial vein of the foot to measure the arm to carotid or foot to carotid circulation time. The average arm to carotid circulation time was 15.6 seconds; the jugular-to-carotid or crude pulmonary circulation time was 10.6 second and the average arm index of venous velocity was 4.5 second. The venous circulation time from the foot was found to be 15.1 seconds. The reliability of the reaction time of cyanide as a measure of the velocity of the blood flow has been shown by the remarkably close agreement with the circulation times obtained with the radon and dextrose methods.

The reaction time of cyanide was constant when sudden clear-cut respiratory reactions were obtained, even though their intensity varied. Repeated estimations of the circulation time with cyanide were feasible after such short intervals as from three to five minutes. Repeated estimations varied two seconds or less.

Method for Obtaining Blood Pressure—Griffith and Collins describe a method for obtaining the blood pressure in the brachial artery by brachial compression with a blood pressure cuff and simultaneous observation of blood flow in the capillaries of the nail bed of the fingers. It consists in occluding the brachial artery with a pressure above systolic, waiting for cessation of the flow in the digital capillaries, and then slowly lowering the pressure until the flow is just resumed. This point is taken as the systolic pressure or, in a case without pulsation as the mean pressure. As the method does not require pulsation, it is especially valuable in those cases in which pulsation is absent. Results obtained are compared with those obtained by auscultation in normal persons. The systolic blood pressure obtained by capillary observation was found to vary between 5 and 12 mm of mercury lower than that obtained immediately afterward by auscultation. One patient without pulsation in the brachial arteries was studied, and the results were confirmed by a direct pressure reading after arterial puncture.

Soy Bean Flour in Infant Feeding—Stearns determined the excretion and retention of nitrogen, calcium and phosphorus of an infant fed milk and various soy bean preparations. The relative proportions of nitrogen, calcium and phosphorus ingested differed with the diets. An increase in the relative intake of nitrogen and calcium as compared to the phosphorus intake resulted in an insufficient retention of phosphorus. Under these conditions the urinary excretion of calcium was tremendously increased and the urinary phosphorus markedly decreased. The excessive excretion of calcium in urine noted with two of the diets is interpreted as evidence of an absorption of calcium greatly in excess of the amount that can be deposited in bone with the limited quantity of phosphorus available. The marked alterations in urinary excretion of phosphate are without apparent effect on the excretion of sulphate and chloride in urine. Excessive excretion of calcium in the urine is accompanied by a shift in the mode of excretion of other bases decreasing the excretion in urine and increasing the fecal excretion. The altered calcium metabolism does not seem to affect the retention of fixed bases other than calcium. The substitution of dicalcium phosphate for calcium carbonate in the soy bean food improved the relative retentions of nitrogen calcium and phosphorus. The modified soy bean food appears to be a satisfactory food for infants. The author concludes that in the feeding of infants the relative proportions of nitrogen, calcium and phosphorus in the diet are fully as important as the absolute intakes of the elements. From the results of this study it is suggested that as the relative proportions of these

elements in cow's milk allow adequate retention of each, this ratio seems a safe guide to follow

Pneumonia in Infants—Ferguson and Tower report two cases of lobular pneumonia in infancy caused by *Bacillus mucosus-capsulatus*. The patients were a twin girl and boy, aged 7 months. The girl contracted the disease first and died on the eighth day. The boy became ill two days after the onset of the illness in his sister but completely recovered after a hospitalization period of thirty-two days. Bacteriologic examination of the throat and tracheal secretion is the most important procedure from a diagnostic standpoint. The extreme pallor of the skin and dehydration, the cough and mucopurulent nasal discharge in the two cases, together with the vomiting and diarrhea, which cleared up early in the disease, are suggestive from a standpoint of differential diagnosis. Pneumonia in infants due to *Bacillus mucosus-capsulatus* may not terminate fatally. The pulmonary involvement is perhaps most often lobular, and the roentgen signs which are characteristic of the disease in adults may not occur in infants.

Retentions of Infants Fed Evaporated Milk—Jeans and Stearns studied the actual retentions of nine healthy male infants fed evaporated milk for periods lasting from eighteen to forty-eight weeks. The evaporated milk used for the feedings was purchased in the open market, diluted with an equal quantity of a 12 per cent solution of corn syrup and acidified with lactic acid. In addition to the evaporated milk one teaspoonful of cod liver oil was given daily to infants of all ages. 1 ounce (30 cc) of orange juice daily to infants under 4 months of age and 2 ounces (60 cc) to older infants. An egg yolk was added to the daily diet at 4 months of age, sieved vegetables at 5 months and sieved fruits at 6 months. In order to have the periods of metabolism comparable the same vegetable (tomato) and fruit (apricot) were given each infant during the periods of study. The growth in length and weight was excellent and exceeded standard rates of growth and the rate of the average male infant. Except in the early weeks when clinical evidences of moderate overfeeding were present, the retentions of nitrogen, calcium and phosphorus were high and were approximately the same as those which had been obtained when undiluted acidified fresh milk was fed. The high retention of nitrogen, high excretion of creatinine and good physical progress are considered evidences of good muscular growth. The high retentions of calcium and phosphorus, early carpal ossification, rapid growth in body length and the absence of clinical or chemical evidence of rickets are considered evidences of good bone growth. From the data presented the authors conclude that evaporated milk when used with dietary supplements is a good food for infants. From the standpoint of permitting good growth and high retentions of nitrogen, calcium and phosphorus, evaporated milk compares favorably with fresh milk given with the same dietary supplements.

Chronic Suprarenal Insufficiency—Packard and Wechsler report a case of malnutritional edema which exhibited an unusual clinical syndrome and a degenerative lesion of the suprarenals at necropsy. The puzzling feature of the case is the fact that, in spite of the continuation of his diet and for no reason that could be demonstrated by clinical and laboratory examinations the patient in the second half of his illness suddenly began to deteriorate progressively. The main features were the complete loss of body fat and an advanced degenerative lesion of both suprarenals with necrosis, regeneration hemorrhages and capillary and venous thromboses. The author points out the similarity between the syndrome and the state or chronic suprarenal insufficiency in animals produced by bilateral suprarenalectomy. They review the literature describing the effect of total and partial innervation and of the various vitamin deficiencies on the suprarenals in both animals and man and suggest that this clinical syndrome heretofore undescribed, is one of chronic suprarenal insufficiency due to the suprarenal degeneration occasioned by malnutrition.

Pernicious Anemia—Goldhamer and his associates studied the early changes in the blood with the onset of the reticulocyte response in two cases of pernicious anemia treated with liver extract intravenously. The blood of the two patients was observed day and night at intervals of four hours for eleven days. The liver extract used in one case was prepared according to the method of Castle and Taylor. The dosage given was 0.1 Gm per kilogram of body weight, which in this case amounted to 10 Gm of the liver extract. The total volume given was 80 cc. The other patient was given a similar extract. This patient received 65 Gm of the extract in a 50 cc aqueous solution. The injections were given slowly, at the rate of approximately 4 cc per minute. Observations of the blood pressure were made before and at frequent intervals after the injection until the pressure became stabilized at the pretreatment level. The blood counts were made according to the usual methods. The hemoglobin was estimated by the Leitz-Sahli apparatus. Complete counts were made twice daily. During the period of observation the patients remained in bed. Each patient was given a routine house diet with no liver or kidney. The reticulocyte response began within twenty-four hours following the administration of the first dose of liver extract, the maximum was reached in eighty-eight and 108 hours (cases 1 and 2). The return to the pretreatment level occurred in 264 hours (eleven days). The red blood cell count in case 1 increased 1,000,000 cells in ten days with a corresponding increase of 24 per cent of the hemoglobin. In the

second case there was also an increase of 1,000,000 cells in ten days, with a hemoglobin increase of 28 per cent. Liver extract (0.1 Gm per kilogram of body weight), when given intravenously, produces an effect lasting at least two weeks. The liver extract used in these experiments is not suitable for clinical use because of the reactions.

Test for Substances in Antipneumococcus Serum—Experiments of Barnes and Kramer show that the production of chills and rises of temperature in twelve normal monkeys (*Macacus rhesus*) by intravenous injections of three lots of concentrated antipneumococcus serum corresponded closely to the responses observed in human cases of lobar pneumonia treated with these serums. A serum essentially chill free in human beings failed to produce untoward symptoms in monkeys; a serum mildly reactive in man produced chills in certain doses in monkeys but not in a smaller amount; a third serum causing chills in two thirds of the pneumonia patients treated produced similar reactions in four of six of the monkeys injected. Intravenous injections into monkeys of alcohol-soluble and alcohol-insoluble fractions of a reactive and a nonreactive serum elicited responses similar to those following the administration of the original concentrated serums.

Tuberculous Peritonitis—Olcott and Paccione studied a series of 109 proved cases of tuberculous peritonitis ninety of which were clinical and nineteen necropsies. In eighteen cases (all clinical cases) no other lesions were found. The follow-up in thirteen of the cases indicates that seven patients lived more

than one year, five lived less than a year and one had died. The average age of the eleven women with clinically uncomplicated tuberculous peritonitis was 15.2 years, and of the seven men 17.7 years. The average age of the seventy women in the entire series was 23.1, and of the thirty-nine men 30.1 years. Of the authors' clinical cases, 73.8 per cent were found in women, while the necropsy incidence was rather higher in men (after allowing for the higher rate of necropsies in the male). The incidence of clinical cases of tuberculous peritonitis in Italians and American-born people with Italian names was two and one-half times that of the hospital admissions as a whole. This group largely represented young women. The necropsy proportion of tuberculous peritonitis was not elevated in these two classes but was comparable to that in all diseases. The authors postulate that the high incidence, yet relatively good prognosis indicates an intermediate degree of tuberculation. In Negroes, on the contrary, the necropsy rate of tuberculous peritonitis was high. Tuberculous peritonitis seems to be definitely decreasing in the authors' hospital. The fallopian tubes showed tuberculosis in thirty-three of the seventy women, and the intestine in forty-one of the 109 cases. Their observations indicate that the tubes are more often secondarily involved from the peritoneum than vice versa. The United States mortality statistics show that deaths from tuberculosis of the intestine and peritoneum are more than 2 per cent of those from all forms of tuberculosis at all ages, while the involvement of these organs in the male is quite close to 2 per cent.

Effects of Virulence of Micro-Organism—Medlar and Sasano made a comparison of the microscopic changes caused by the same strain of tubercle bacillus in the state of high and of low virulence. The virulent bacilli caused an acute inflammatory response in the normal nonallergic rabbit wherein the neutrophils predominated. The bacilli of low pathogenicity called forth monocytes and lymphocytes, thus giving an inflammatory reaction of a chronic type. Abscesses, caseation and cavitation were regularly produced in normal nonallergic rabbits infected with bacilli of high virulence while tubercle, giant cells, lymphocytic infiltration and fibrosis were predominant in those infected with bacilli of low virulence. Classic tubercle is a retrogressive healing lesion. As such it is found in virulent infections on allergic soil or in nonvirulent infections on nonallergic soil. The present distinction between the pathology of first infection and reinfection is open to serious question because the degree of virulence and dosage of the infectious agent are not duly considered. The same criticism may be justly made of the distinction drawn between tuberculosis in the child and in the adult.

Surgery of Diabetic Gangrene—Eliason analyzed a group of 170 diabetic patients operated on for gangrene. Gangrene affected 13 per cent. More than 95 per cent of gangrene was in the lower extremity. Of the 170 patients 50 per cent did not know of their diabetes until gangrene occurred. Open gangrene with infection is the commonest form and gives the poorest results (87 per cent of this series). Infection played

a part in 95 per cent of the fatal cases, *Bacillus welchii* and streptococci being the chief offenders. Early surgery in properly prepared diabetic patients is essential. Preoperative insulin, carbohydrates, fluids and perfringens antitoxin are necessary. High amputations (midthigh)—76 per cent were midthigh and single—with drainage in infected cases, gave the best results. Transfusion and guillotine methods were the rule without tourniquet. Spinal anesthesia was used in 80 per cent of cases, local in 17 per cent. Diabetic patients with gangrene have had seven years added to their lives by modern methods of treatment. Operative mortality (twenty-four hours) was 35 per cent, hospital mortality, 41.8 per cent, one year mortality, 55 per cent. In the last sixty-seven cases there was a slight improvement over the previous series. Hospital days of the entire 170 patients was 365, of the survivors, 622 days. Only 10.4 per cent of these last sixty-seven patients are alive after eighteen months. Education of the patient, the physician and the surgeon is essential for the best results.

Pulmonary Embolism—Griswold presents two unsuccessful cases of pulmonary embolectomy. The first case illustrates some difficulties of diagnosis, the second the results of a too conservative attitude. The author believes that the failure of the Trendelenburg operation in the second case which should have been ideally favorable for the procedure, was due to the fact that oxygen was administered over a long period, improving the clinical appearance and masking the true condition of the patient until the overburdened right heart had lost all recuperative power after pumping against an almost completely obstructed pulmonary system for over eight hours. Operation was not carried out earlier because the patient's unchanged appearance led to the belief that she might recover spontaneously. If oxygen had not been administered her apparent condition would have become so bad as to force operation shortly after the onset. The author feels that, if the operation had been undertaken before the myocardium and respiratory centers had become exhausted it would have been successful. He concludes that this procedure, if carefully studied as to diagnosis, indications and technique is the only hope of saving a large number of patients since prophylactic measures directed against the incidence of pulmonary embolism have so far shown themselves of no avail.

Tobacco and Thrombo-Angitis Obliterans—Maddock and Collier present a study on the effect of tobacco smoking, largely in the form of cigarettes, on young adult smokers which demonstrates a consistent increase in blood pressure and pulse rate and a decrease in the skin temperature of the fingers and toes. Control experiments gave definite evidence that these effects were due to active products absorbed from the tobacco smoke. Nicotine administered intravenously in quantities not greater than that theoretically absorbed in the smoking of one or two cigarettes produced comparatively analogous changes. Greater effects were noted when the subject inhaled rather than merely puffed, and also with rapid smoking more than with slow smoking. The decrease in the peripheral skin temperature on smoking must be due to increased vasoconstriction. The decrease in the peripheral skin temperature was shown to be carried out through the sympathetic system. By increasing peripheral vasoconstriction smoking reduced the blood supply of the fingers and toes of the young adults studied. With several subjects the reduction lasted more than thirty minutes from the time of cessation of smoking and generally was of longer duration in the toes than in the fingers. In two cases of thrombo-angitis obliterans, smoking produced the same cardiovascular response as in the normal subjects. The already deficient circulation in the feet of these two patients was further reduced by smoking. The authors do not offer the data presented as evidence that tobacco smoking is the etiologic factor in thrombo-angitis obliterans. The occurrence of the disease in persons who have never smoked precludes that opinion. They do not doubt that prolonged or marked vasoconstriction for a sufficient period may initiate organic vascular occlusions. The changes may occur not only in peripheral arterioles, capillaries and venules but also in peripheral arteries and veins as a result of zones of poor nutrition in their walls through vasoconstriction of their *vasa vasorum*. The demonstrated vasoconstrictor effect of tobacco smoking would lessen or nullify the benefits of all conservative treatment. The experimental data presented

form a rational basis for the clinical conclusions as to the deleterious influence of tobacco smoking on the progress of thrombo-angitis obliterans. Its use definitely further decreases the already deficient circulation in the extremities of persons with the disease.

Intradermal Treatment of Lymphogranuloma Inguinale—For the past eighteen months Wien and Perlstein have had under observation twelve men and four women with lymphogranuloma inguinale. One of the men presented the anorectal syndrome usually seen in women. Their earliest patients were given subcutaneous injections of Frei's antigen as suggested by Hermans and improvement was noted after months of treatment. The authors noted in some of their patients that following the diagnostic Frei tests there was a cessation of the activity of the lesions together with an improvement in the general condition. They treated the patients coming under their observation subsequently with intradermal injections of Frei's antigen. They gave 0.1 cc of the antigen intradermally at intervals of from three to five days and an infiltrated papule formed at the site of each injection within forty-eight hours. When a marked local reaction occurred at the site of treatment, successive injections were made at remote sites. They also observed a reversal of the Frei reaction to negativity in three patients after each had received an average of eleven injections of the antigen into the forearm given at intervals of three days but positive results were obtained when the same Frei antigen was injected intradermally into the buttocks or into the backs of the same patients. After a period of rest of from two to three weeks positive Frei tests were again obtained on the forearm. The authors feel that the negative Frei tests were dependent on a temporary local desensitization of the forearm. There was a decided clinical improvement immediately after the first injections; new lesions ceased forming; the sinuses stopped discharging, and healing and fibrosis were hastened. In the patients with the anorectal syndrome there was alleviation of the rectal symptoms with improvement in the general condition. The advantages of intradermal injections of Frei's antigen in the treatment of lymphogranuloma inguinale are that less antigen is required and that the beneficial results are obtained in a shorter period of time than with the subcutaneous method. The intradermal method does not require any specially prepared antigen, and there is no constitutional reaction such as was noted by Hermans and Gay-Prieto.

Sporotrichotic Chancre—Campbell and his associates report a case of sporotrichosis in which only the primary, or chancre stage was manifested. The chancre was reproduced in a rat with recovery of the organism and a cultural pleomorphism was demonstrated following the single exchange of hosts. Sporotrichum was absent. This might have been due to the strain of the fungus or because the observations of others were made on material obtained from secondary lesions.

The treatment consisted of 15 grains (1 Gm) of sodium iodide given intravenously every fourth day. In the course of two months, complete healing was obtained. Approximately seven months later the patient was requested to return for observation and for the making of photographic records. At this time the area appeared even less prominent than on the date of her discharge, and the results of a general physical examination were normal.

Diffuse Sclerosis—Lowenberg and Hill present the clinical and anatomic conditions found in a further case patho-anatomically and histologically identical with the observations of Merzbacher in a child in whose family a peculiar hereditary disease of the brain had occurred in several generations, a case from the same family reported by Spielmeier and Liebers, and two sporadic observations, one by Bielschowsky and Henneberg and one by Bodechtel, showing few similar clinical trends. This condition is characterized by a peculiar degeneration of the white matter of both hemispheres of the brain and that of the cerebellum, the pons, the medulla and even the spinal cord. Within the destroyed areas there remain numerous perivascular myelin islands so that the destruction of the white matter is not complete.

Paroxysmal Lacrimation—Ford draws attention to a phenomenon that he has observed in four cases of facial paralysis of peripheral type. In each instance the paralysis was complete and persisted for several months. Regeneration of the nerve and the return of power in the face were accompanied by facial contracture and abnormal associated movements. Coincidentally with the return of voluntary movement excessive lacrimation on the affected side appeared whenever the patient ate or even took any rapid substance into the mouth. This phenomenon never appeared under other circumstances. This symptom bears no relation to the common overflow of tears from the affected eye during the early stages of facial palsies when the lower lid is relaxed and the punctum of the tear duct is everted. The condition that the author describes does not develop until the paralysis has disappeared and the lid is again in its normal position. Moreover it is not constant but paroxysmal and invariably associated with relaxation. In each case occlusion of the lacrimal duct was ruled out.

Xanthomatosis—Davison describes a case of xanthomatosis presenting diabetes insipidus, defects in the membranous bones and changes in the nervous system. In addition to the deposits of lipid cells found in most of the organs, the white matter of the central nervous system was the seat of numerous demyelinated plaques filled with compound granular corpuscles and giant glia cells. These two types of cells found in the neural structures are considered analogous to the foam cells and the reactive type of cells (fibrosis and inflammatory cells) demonstrated in other organs. In this disease the hypophysis was the seat of deposits of foam cells, while the tuber cinereum region showed evidences of reactive phenomena (gliosis, fibrosis and inflammatory cells) and occasional compound granular corpuscles and giant glia cells. The process is one of disturbance in lipid metabolism (cholesterol) and in some respects resembles Gaucher's and Niemann-Pick's diseases and possibly amaurotic family idiocy.

Blood-Cerebrospinal Fluid Barrier—Rothschild and Burke report the results of a study of the blood-cerebrospinal fluid barrier by Walter's bromide method in fifty-three cases of alcoholic mental disorder. Twenty-four showed low initial ratios for the distribution of bromide and values above 33 were obtained in five. The proportion of low ratios was somewhat greater in Korsakoff's psychosis and chronic alcoholism than in delirium tremens and alcoholic hallucinosis. Most of the cases presenting high ratios were atypical clinically. The distribution of bromide between the blood and the cerebrospinal fluid was investigated in fourteen patients with schizophrenia who were intemperate. The initial determinations yielded low ratios in eight and a high value in one. The authors' observations suggest that the excessive use of alcohol tends to lower the ratio of distribution of bromide regardless of the presence of a particular type of psychosis. The same tendency occurred in patients with chronic alcoholism who had at no time been psychotic. The ratios of distribution of calcium sugar and chlorides between the blood and the cerebrospinal fluid were determined in a number of the patients for whom the bromide test was performed. Essentially normal results were obtained. There was no relation between the ratios of distribution of bromide, calcium, sugar and chlorides.

Dislocation of Gladiolus Behind Manubrium Sterni—Stahl reports a case of dislocation of the gladiolus behind the manubrium. A preliminary roentgenogram was not taken because of the visible suffering of the patient. He was given nitrous oxide anesthesia and an attempt was made at reduction by extension of the dorsal spine and pressure upward on the manubrium, but this was unsuccessful. Therefore the front of the chest was prepared and a small stab wound was made over the gladiolus 1 inch below the site of injury and a heavy corkscrew was then turned into the gladiolus. A sharp two-toothed retractor was then stabbed through the skin into the lower end of the manubrium and reduction was easily accomplished. Following this, a cross clavicular splint was worn for four days and the front of the chest was strapped with adhesive plaster. The patient was comfortable on awakening. A roentgenogram taken the day after reduction in profile and antero-posterior views, showed good position, and the separation to have been at the junction of the manubrium with the gladiolus with no fracture of the ribs or other bony structure of the chest. The patient made an uneventful recovery.

Suprarenal Cortex in Thyroid Disorders—Weinstein and Marlow used suprarenal cortical extract (Swingle-Pfiffner) in the treatment of five normal persons, seventeen patients with hyperthyroidism and two patients with hypothyroidism. The administration of raw suprarenal cortex by mouth or the parenteral administration of the suprarenal cortical hormone gave no definite improvement in the general nutrition of the patients or any diminution in the signs of the disease that was present and did not affect the normal persons. The authors suggest that the method employed in the extraction of the cortical tissue gives a product that contains a hormone capable of maintaining life in bilaterally suprarenalectomized animals, but not the hormone postulated to regulate thyroid function. It is known that in suprarenalectomized dogs kept in a state of good nutrition for periods as long as one year by use of the suprarenal hormone the thyroid gland does not show hyperplastic changes. On the contrary, atrophy of the thyroid is

usually seen. If the extract employed contained only the hormone that maintains life and not the substance that exerts the regulatory action on the thyroid, one would certainly expect to find hyperplasia in the thyroid cells. This fact supplies added evidence that the extract employed should have produced retardation of the overactivity of the thyroid in the patients, if the theory advanced by Marine and his associates is tenable.

Inorganic Salt and Water Metabolism—The Wileys and Waller fed sodium potassium and ammonium chlorides and sodium bicarbonate in equivalent quantities to a normal man on a salt-poor maintenance diet. Sodium chloride administration was accompanied by a negative potassium balance, an early sodium and chloride retention followed by an increased excretion of both, an increased excretion of both urinary and fecal calcium and slight changes in body weight. The ingestion of potassium chloride caused an increase in the excretion of sodium and potassium, resulting in a negative balance for each of these elements, a decrease in the inorganic phosphates, an increase in inorganic sulphates, and no marked change in the body weight. The ingestion of ammonium chloride was accompanied by negative balances in sodium and potassium, the latter being quite marked slight negative balances for calcium and magnesium, and an increased ammonia formation and titratable acidity. The body weight declined during the feeding periods indicating a loss of body water and in the control periods the gain in weight more than balanced this loss. Sodium bicarbonate caused a slight retention of water, a negative sodium balance, a positive potassium balance, a slight decrease in chloride excretion, and a marked decrease in ammonia formation.

Mineral Metabolism in Nephrosis—Hoffman and Post made careful metabolic balance experiments of four patients with nephrotic edema for the relationship of the mineral metabolism to edema. They found that the ingestion of water, sodium or chloride produces a transudation of these substances across the capillary walls to keep the osmotic relations of the plasma and extracellular fluids somewhere near normal, until the excretion by the kidneys restores the normal body content. A low serum protein concentration produces a tendency for accumulation of extracellular fluid because of the lag in the return of fluid into the blood stream. The extent of this accumulation is determined among other factors, by the speed with which the kidneys carry on the excretion of water, sodium and chloride. An adequate excretion of sodium (and therefore of its quota of water and chloride) in nephrosis is apparently possible only when the serum sodium concentration is at a normal or higher than normal level. The serum sodium concentration seems to be related to that of red cell potassium, and factors that raise the latter may raise the concentration of serum sodium and thereby increase the urinary excretion of sodium.

Leukocytosis Following Liver Extract—Powers and Murphy determined the total white cells and the total number and proportion of polymorphonuclear neutrophils in the peripheral circulating blood of twenty-one normal subjects before and after the intramuscular injection of liver extract. The subjects were divided into two groups: those to whom the extract was given at 9 o'clock in the morning and those who received the drug at 5. The first group was further divided in two subgroups, ambulatory and recumbent. The average maximal increase in the total number of white cells of the ambulatory group was 94.1 per cent higher than the average of all control counts and occurred seven hours after the extract was administered. The greatest individual response in this group was 185 per cent and the lowest was 23 per cent above the average of the four control counts made on each of these two subjects the previous day. The average maximal increase in total white cells of the patients of the recumbent group was 72 per cent above the normal level and occurred six hours after the injection of liver extract. The highest and lowest individual responses in the members of this group were 101 per cent and 20 per cent above the normal averages of these two subjects. One patient with influenza accompanied by leukopenia on the first day of the experiment showed a well marked leukocytosis following the injection of liver extract. A similar increase in the total number of white cells and the total number and proportion of polymorphonuclear neutrophils was obtained in the

second group of normal subjects, who received the drug four hours earlier than those of the first group. The leukocytosis in every instance was due to an increase in the polymorphonuclear neutrophils.

Thyroid and Potassium Iodide in Cholesterol Atherosclerosis—Turner observed that whole thyroid when administered simultaneously with cholesterol prevented the atheromatous changes produced by the latter in the aorta of rabbits in seventeen of nineteen animals. Thyroxine was less effective in this series, as atherosclerosis occurred in eight of eleven rabbits. Potassium iodide also exerted a strong protective action as aortic lesions were present in only one of a series of twelve rabbits fed cholesterol and potassium iodide concurrently. The effectiveness of potassium iodide was not shared by potassium bromide or potassium chloride. A relationship was noted between the level of the cholesterol in the blood and the development of atherosclerosis. In general, the aortic lesions accompanied a hypercholesteremia.

Thyroidectomy and Potassium Iodide—According to the studies of Turner and Khayat, thyroidectomy in itself does not cause a rise in blood cholesterol or the development of atherosclerosis in young rabbits. The feeding of cholesterol produces hypercholesteremia and atherosclerotic lesions in rabbits regardless of the presence or the absence of the thyroids. Potassium iodide prevents the usual hypercholesteremia and atherosclerosis of the aorta in normal rabbits fed cholesterol, but when the thyroids are removed this protective action disappears.

Calcification of Tissues by Toxic Doses of Viosterol—Reed and his associates made analyses for the calcium and phosphorus content of twelve tissues from thirteen normal dogs and from fourteen dogs that had received by intravenous injection toxic doses of viosterol 10,000 X. Statistical treatment of the data shows that the calcium content of any tissue may be significantly increased by viosterol administration although wide variations may occur certain tissues showing no increase.

The magnitude of the increase in the calcium content is not correlated with the viosterol dosage but seems to depend on some undetermined individual factor or factors. The phosphorus content, while widely variable among individual animals, was affected by viosterol administration in a much less constant manner, if at all.

Effect of Certain Fruits on Urinary Acidity—Saywell observed the following results in his experiments with men on a basal diet and on the same basal diet supplemented by pears, peaches, apricots and dried sulphured apricots. 1. An average increase of the urinary reaction of approximately 0.7 pH unit was produced by 1,000 Gm of fresh Bartlett pears; an average of 0.85 pH unit by 1,260 Gm of canned peaches; and an average of 1.2 pH units by an equal quantity of canned apricots. An average increase of 1.45 pH units was produced by 300 Gm of dried sulphured apricots. Both kinds of apricots produced alkaline urines. 2. Corresponding decreases in both the ammonia excreted and in the total acidity were noted. The average changes produced by both kinds of apricots were considerably larger than those resulting from either the peaches or pears. 3. There was an increase of the alkali reserve, estimated according to the method of Fitz and Van Slyke, equal to or above the normal for each subject. This increase was marked for both kinds of apricots. 4. There appeared to be a correlation between the alkalinity of the ash and the reaction of the urine in the case of pears and peaches. A more basic reaction was associated with a higher ratio of soluble alkalinity to insoluble alkalinity of the ash. Compared with the peaches the apricots appeared to produce an even more basic reaction with approximately the same ratio of soluble alkalinity to insoluble alkalinity. 5. A slight increase occurred in the organic acids excreted when pears, peaches or the two kinds of apricots were added to the basal diet. 6. The average proportion of oxidations of the organic acids of the pears, peaches and the two kinds of apricots were similar, averaging 94.7 per cent. 7. Apparently the added inorganic sulphur in the apricots does not reduce the basic effect of the apricot on urinary acidity.

*Black Widow Spider Bitten or Hourglass Spider. W. A. Hayward. Coffeyville—p. 261

Black Widow Spider—Hayward states that the black widow spider is the chief poisonous spider in the United States. It has fangs and a poison sac and is capable of expelling a colorless venom containing a highly neurotoxic element. Persons may not know they are bitten, as the sensation is much like the extraction of a hair or the prick of a pin and no local reaction follows immediately; the spider is frequently not seen. However, a small wheal is present, on the apex of which is found a puncture wound the size of a pinhead. Some itching and burning are noted at the time of the bite. A few hours later a purpuric spot may appear, soon followed by an area of induration and extreme soreness, and frequently a slough occurs at the site. This may be caused by the venom or local infection for cases of pyelitis, cellulitis, septicemia and erysipelas have been reported following the bite of a spider. The general symptoms appear from ten minutes to several hours after the bite depending on its location. Often there is severe pain radiating from the site of the wound and finally extending over the entire body accompanied by nausea, vomiting, dyspnea, persistent hiccup, profuse perspiration and urinary retention. There may be edema of the face, urticarial rash covering the body, accompanied by intense itching, increased blood pressure, leukocytosis and a fever, which seldom reaches 102 F. The symptoms usually subside in a few hours and the patient is able to be about in two or three days. However, several deaths have been reported as resulting from the bite of this spider. The treatment is symptomatic and includes sedatives, elimination and stimulation. Hypodermic injections of morphine are indicated and usually large doses are required. Strychnine and caffeine are useful. Hot packs of a 50 per cent solution of magnesium sulphate over the region of the bite give relief. Good results have been obtained by the use of convalescent serum, but as yet no serum has been manufactured from lower animals.

Lipoma of Glosso-Epiglottic Space—Briglia presents the case of a Negro woman who complained of extreme difficulty in swallowing, with increasing fulness in her throat simulating the presence of a foreign body which she almost constantly endeavored to swallow. Concomitant with these symptoms, she noticed hoarseness, thickness of speech, occasional cervical pain, increased salivation, attacks of cough and difficulty in breathing. Weight was lost progressively, although her appetite was good. Food and liquids which she believed to be completely swallowed were frequently ejected from her mouth. External examination of the neck and intranasal examination proved essentially negative for any pathologic changes. Examination of the pharynx revealed a single tumorous swelling just posterior to the base of the tongue. The apex of the growth (the size and shape of a small pear) pointed downward toward the larynx, its base extended just above the dorsum of the tongue and it was attached by its pedicle to the glosso-epiglottic space. It bobbed up and down with each attempt to swallow. A Lewis snare was applied over the mass around the pedicle and the tumor removed. This was followed by a negligible oozing of blood from the stump which stopped readily. Gross examination of the specimen revealed a lipoma confirmed by histologic examination. It weighed 14 Gm and was 4.5 cm long, 3 cm wide and 3.5 cm in thickness. Three days later the patient was reexamined by the laryngoscope, and it was found that there remained some of the stump of the growth formerly removed. This was removed with a snare and cupped forceps. Several days later following the removal of the remaining tissue, the surface of the glosso-epiglottic space was smooth, healing complete and recovery uneventful.

Hepatosplenography—Yater states that thorium dioxide hepatosplenography has its greatest place in the diagnosis of those diseases of the liver which are not regularly associated

with jaundice, particularly cirrhosis, syphilis, metastatic carcinoma and primary neoplasia. In atrophic cirrhosis, one of two appearances is presented in the roentgenogram. Either the liver, which is usually shown to be small, is diffusely mottled, or it is of homogeneous density but less dense than normally. In both types of cirrhosis there is always a moderate splenomegaly. Syphilitic cirrhosis may resemble atrophic cirrhosis pathologically so closely that it gives a roentgen appearance indistinguishable from it. But in that type of gummatous syphilis of the liver which results in gross deformity from scarring, a distinctive picture results. The liver is seen to be greatly lobulated and deformed, and it is frequently less dense than normally. Metastatic lesions appear as more or less round, nonopaque usually multiple areas, surrounded by a halo of increased density. This appearance is due to the fact that cancer tissue does not contain reticulo endothelial cells. In addition, the spleen is practically never found to be enlarged. A primary neoplasm is diagnosed when a rounded, nonopaque area is seen without the halo of increased density. In diffuse primary carcinoma, the picture resembles closely that of cirrhosis. Abscesses and cysts in the liver are readily visualized. It is possible that traumatic rupture may be detectable.

Operation for Slipping Patella—Soutter outlines an operation for slipping patella in which, after the position for the supporting fascial ligament is selected, an incision is made above or below this line so that a flap may be turned back down to the fascia. The patella is tunneled obliquely from above downward and from without medially. At about the middle of this tunnel a window is opened in the top. A similar tunnel is made in the tibia in approximately the same line and well to the mesial side of the tibia. Through the ridge of bone that overlies the fascia on the mesial side of the tibia a tunnel is made with an osteotome instead of drilling. While the osteotome is in place in the tunnel, a window is cut down to it through the overlying fascia. The ligament in the patella is passed from the mesial side of the tunnel upward and the loose end, as it emerges from the outer side of the patella, is folded over the top of the patella and tucked in through the window, emerging below at the entrance to the tunnel on the mesial side of the patella. Two catgut sutures are placed in the fascia. In a similar way the fascial ligament is tucked in on the outer side of the tibial tunnel. The loose end is then brought out at the mesial side of the tibia folded over and tucked in through the window. The two loose ends are approximated passed through each other twice and sutured with catgut.

Tensor Fasciae Femoris Transplantation—Legg reports an operation to strengthen the abductor power of the thigh in cases in which the gluteus medius has been weakened by infantile paralysis by transplanting the origin of the tensor fasciae femoris backward along the crest of the ilium to directly above the great trochanter. The incision is made along the crest of the ilium starting a little behind the middle and going forward to the anterior superior spine then downward along the inner border of the tensor fasciae femoris to the mid thigh. The skin and subcutaneous fat are reflected back, exposing the fascia lata. The fascia between the tensor fasciae femoris and the sartorius is divided the division being carried down along the anterior border of the tensor fasciae femoris and continued down along the anterior border of the iliotibial band. At this stage the fascia must be freed from the great trochanter anteriorly in order to get the muscle directly over the trochanter. The leg is abducted about 35 degrees and the origin of the muscle is sutured with number 18 silk to the crest in a line directly above the great trochanter. The subcutaneous fat is then sutured with catgut the skin with black silk. A dressing is applied and the leg is put into a bivalved plaster spica which has been made previously to maintain the position of 35 degrees abduction. It is the author's custom to dress the wound on the eighth or ninth day and to begin light muscle training at the end of twelve days increasing it gradually. The patient is allowed to walk in an abduction splint at the end of six weeks. The abduction splint is removed at the end of three months.

Countersinking the Astragalus in Paralytic Feet—The technique of Brewster for countersinking the astragalus in paralytic feet is as follows. An incision is made on the lateral side of the foot from the head of the astragalus convex down

ward to the posterior superior surface of the os calcis. Through this incision the skin and subcutaneous tissues are divided. The peroneal tendons, peroneus longus and brevis are exposed and retracted from the field of operation. The fossa between the inferior surface of the astragalus and superior surface of the os calcis is denuded of tissue. Beginning at the junction of the neck and body of the astragalus, its inferior surface is removed in a plane parallel to the sole of the foot. Taking advantage of the bony elevation on the anterior superior surface of the os calcis, a chisel is driven through the os calcis at right angles to the sole of the foot and just posterior to the cartilage of the calcaneocuboid joint, from the lateral side to the medial. At right angles to this, the superior surface of the os calcis is removed parallel to the sole of the foot anteroposteriorly, until all the cartilage of the os calcis taking part in the joint between the astragalus and os calcis is removed. The head and neck of the astragalus are next removed at right angles to the sole of the foot, so as to remove part of the cartilage on the superior surface of the astragalus, which forms the joint between the tibia and the astragalus. After the foot is displaced backward, it is then determined at what point the posterior part of the astragalus and os calcis are to be removed. The posterior part of the astragalus is removed at right angles to the sole of the foot. Next, as much of the bony prominence on the posterior superior surface of the os calcis is removed at right angles to the sole of the foot as is necessary. The two right angles are made to fit as the two anterior ones were, and the countersinking of the astragalus is accomplished. This procedure gives lateral stability, and it limits plantar flexion and dorsiflexion to the degree desired. The foot appears nearly normal and is functionally good.

Trauma and Encephalitis—Rabiner presents a series of cases with a clinical picture of epidemic encephalitis in which the chief interest is a history of trauma. He attempts to determine what effect such traumas may have on this disease. Cases are presented in which the trauma plays an important part in the production of epidemic encephalitis and, similarly, other cases in which the trauma is simply a coincidental or chance occurrence. He concludes that, following an injury to the head in which there is evidence of intracranial involvement, the minimal degree being a cerebral concussion, a later developing epidemic encephalitis syndrome must be regarded as having been influenced in its production by the trauma. A patient who has had an acute epidemic encephalitis may have chronic manifestations, such as parkinsonism initiated or produced by an injury to the head. Such an injury must be severe enough to produce at least the symptoms of cerebral concussion. A partial clinical evidence of chronic encephalitis, such as a tremor of the hand or the loss of associated movements, may be regarded as indicative of the full syndrome developing. If such an individual then has an injury, the advance in symptoms

is not attributable to the trauma. An injury to any portion of the body, excepting the skull, particularly when not associated with signs of cerebral concussion, plays no part in the clinical course of epidemic encephalitis.

Nirvanol Treatment of Chorea—Dennett treated ninety three cases of chorea with nirvanol, a urea and glycol preparation phenylethylhydantoin. The attacks have terminated favorably in all. The patient should be put to bed for observation for two or three days before the drug is used in order to ascertain that he is not suffering from any other disease. From 5 to 15 grains (0.3 to 1 Gm.) of nirvanol is given daily, the latter dose being given to large heavy children. The author's maximum dosage was 215 grains (14 Gm.) for the entire period. The average dosage was 80 grains (5.2 Gm.) for the entire period of treatment. Usually the drug is given for from seven to ten days, and following its withdrawal there is a rest period of two weeks in bed. The drug has brought about a train of symptoms resembling an acute exanthem in children. The drowsiness begins on the third or fourth day and varies extremely in intensity. The density of the stupor is alarming but it is a natural quiet sleep and there are no ill effects. Smaller doses should be given in the summer. The drowsiness varies from sleepiness to stupor, and, unless it is too deep and accompanied by prostration, it is not an indication for stopping the treatment. Along with this drowsiness, which clears up in two or three days after withdrawal of the drug, there is an exacerbation of the choreiform movements. The child becomes more active when awakened. Fever appears about the seventh or eighth day. It has been more than 102 F. in 40 per cent of the patients, less than 102 F. in 40 per cent, and in 20 per cent there has been a temperature of 100 F. or below. The duration of the fever is four or five days, and when the temperature rises it is best to stop the drug. Two indications for stopping the drug are fever and rash. The rash also appears about the seventh or eighth day. The rash varies—sometimes it is like measles, or an urticaria or even an edema of the eyelids, or a scarlet fever rash with hyperemia of the soft palate. It disappears in four or six days.

Treatment of Hookworm with Hexylresorcinol—Molloy administered a total of 1,784 treatments of hexylresorcinol. No toxic symptoms from the drug were observed. Slight gastric irritation occurred occasionally, but nausea was rare and vomiting did not occur. Owing to the action of hexylresorcinol on the gelatin of capsules, the drug is best administered in sugar-coated pills. Full therapeutic (1 Gm) doses of the drug removed from 65 to 72 per cent of hookworms under field conditions. The efficacy of the drug is greatly lessened if it is not given on an empty stomach or if food is taken shortly after administration. The efficiency of the drug would probably be increased if the intestinal tract were cleared of extraneous matter by a purge and this would be a procedure that could be recommended in the treatment of individual cases. From 93 to 98 per cent of the ascarids harbored by the patients were expelled by a single treatment. In the treatment of whipworm infestations the drug appears to be less effective than earlier reports indicated. It appears, however, to be the most effective drug against this parasite at the present time. Only the latex of the liguero (wild tropical fig *Ficus hirsutifolia*) removes a larger percentage of the worms. The administration of a purge two hours after the drug lessens its anthelmintic effect. Owing to its delayed action phenolphthalein may be administered simultaneously with the drug without lessening its efficiency against hookworm and ascaris. If saline purgatives are employed these should not be administered until several hours later preferably the following morning. In the treatment of hookworm disease, a single dose of hexylresorcinol lessens the worm burden to the extent that the patient is relieved of most of the symptoms. It does not entirely eliminate the danger to others since the majority of persons treated still harbor a sufficiently large number of worms to be considered carriers. In treatment campaigns that are being conducted for the purpose of reducing mass infection, a second treatment (preferably of some anthelmintic possessing a more selective action against hookworm, such as tetrachlorethylene carbon tetrachloride or thymol) would seem to be indicated.

Treatment of Pellagra—Ramsdell treated twenty-five cases of pellagra with liver extract, intramuscularly, without a death and with rapid clinical improvement. He believes that, in severe cases or in patients with marked depression who refuse to eat, liver extract will save many who would not recover under dietary treatment. A combination of liver extract and dietary treatment would probably give better results than either alone. The author's treatment consisted of a general diet without the addition of any foods known to be rich in vitamin G. The patients were kept in bed and given 2 cc of liver extract no 343 intramuscularly, once a day. No medication of any kind was used, and the skin lesions were left open and untreated. There were no systemic reactions from the injections, and none of the patients objected seriously to them. The injections were usually given in the deltoid or gluteal muscles. The amount of liver extract required for various patients will vary according to the amount of existing deficiency. The author does not attempt to assign any definite reason why liver extract should be an effective treatment for pellagra but believes that its vitamin B₂ content is the cause.

Ulcerative Syphilitic Lesions of the Stomach—The criteria on which Pusch made diagnoses of syphilis of the stomach in four cases are (1) clinical courses typical of those generally accepted as characteristic of gastric syphilis, (2) achlorhydria in three cases, subacidity in the fourth, (3) a positive Wassermann reaction in three, in which case syphilitic infection was manifest in the presence of classic gummas in perigastric lymph nodes, and (4) an associated gastric lesion of the structural features constant in all cases, features not characteristic of other known lesions of the stomach but histologically characteristic of syphilis. As pointed out by Warthin, the characteristic lesion of tertiary syphilis consists of perivascular aggregations of plasma cells and lymphocytes associated with proliferation of fibrous tissue. Such lesions are not pathognomonic of syphilis, yet differences in degree composition and disposition can be detected between the average syphilitic and the average nonsyphilitic lesion. The gumma is the classic lesion of tertiary syphilis but not the characteristic lesion. In the author's cases the sparsity of gummas and the absence of a structural disintegrative type of necrosis and the paucity and the small size of the giant cells suggest a nontuberculous nature. Fungi were not observed. There was no indication of neoplastic disease. In all four cases the lesion consisted of a shallow ulceration of irregular outline, several centimeters in diameter located at the pylorus with annular involvement of the orifice sometimes continued into the duodenum. The bordering mucosa usually was hyperplastic and edematous. The wall at the site was thickened and indurated. The annular shape

of the lesion with irregular margin, distinct from the smaller, round, deep, peptic ulcer, conforms with the configuration assumed by syphilitic lesions of the intestine, including rectal strictures

Intravenous Urography—In the diagnosis of tuberculosis of the kidney by intravenous urography Pask carries out the injection as in any intravenous injection, using an ordinary 20 cc syringe and injecting the contents slowly. It has been his practice to take a series of roentgenograms at intervals of five, ten, twenty and forty minutes after the injection because in a single roentgenogram some part of the ureter or pelvis, or both, will be in systole and that part will not contain any of the contrast substance. The only parts delineated in a given roentgenogram are those that are in diastole at the time of taking the urogram. The dynamics are constantly changing owing to peristalsis. By intravenous urography visualization of both sides of the urinary tract and the relations between the various parts can be studied in a series of roentgenograms. It is thus possible to demonstrate the presence of both kidneys and to contrast their relative functional activity. It has been proved by animal experiment that neopax (known abroad as uroselectan B) is excreted by the glomeruli of the kidneys and not by the tubules and that before it passes into the renal pelvis, the general outline of the kidney is often well seen because the contrast substance is present in the glomeruli of the kidney. As the neopax passes to the calices and pelvis and along the ureters, any abnormality can be noted. In cases of tuberculosis of the kidney there is frequently seen irregularity of the outline of the pelvis and calices and dilatation of the ureter. If the kidney substance is completely destroyed on one side, no urogram will be obtained on that side. Neopax, 5 per cent, in the urine is said to be sufficient to give a roentgenogram. In normal kidneys a good roentgenogram is sometimes obtained as early as five minutes after injection, but in the tuberculous kidney the rate of excretion is retarded and occasionally six hours is necessary before a sufficiently dense pyelogram is obtained.

Recurrent Volvulus of Pelvic Colon—The study of twelve cases has convinced Ligat and Overend that recurrent sigmoid volvulus is a frequent source of obscure symptoms.

Excessive length of the pelvic colon may be due to congenital elongation, apparently due to arrested development of the mega sigmoid colon, associated with gross dilatation of the lumen, or the acquired type of colon due to dietetic habits. The primary factor in volvulus of the pelvic colon is its abnormal length. The secondary factors are elongation of the pelvic mesocolon, narrowing of the base of attachment of the pelvic mesocolon to the sacrum, and formation of an axis of rotation by adhesions or by close approximation of the entrance and exit loops of a coil of intestine. The authors classify provisionally the types of recurrent sigmoid volvulus into three groups. 1 The first type shows severe and continuous constipation, perhaps with some discomfort or aching in the back or abdomen. Some are chronic and do not show anything in the way of a crisis; in others a minor crisis occurs periodically, in which the symptoms are accentuated. 2 The second group may either have some constipation during the latent period or may be free from symptoms during this time. These patients are subject to recurrent attacks of torsion, causing severe spasmodic pain and local distention of the intestine but the torsion is not sufficient to occlude the veins. 3 In the third group the torsion during a crisis is more marked and interferes with the venous return. In such cases recurrent attacks of severe pain occur with local distention and watery or blood stained diarrhea. The venous congestion induced by the twist causes a transudation into the intestinal lumen, which is stored in the affected loop until it is set free by spontaneous reduction when it appears as diarrhea watery or blood stained according to the degree of torsion. The occurrence of the diarrhea after rather than during the attack of pain is thus a point of diagnostic importance. The gratifying results following excision of the redundant loop have confirmed the authors in the opinion that this is the method of choice. In cases in which the operation is contraindicated an attempt should be made to relieve the symptoms by fixation of the loop while in patients who are obviously bad surgical risks recourse must be had to such methods as colonic lavage and mild aperients and the adoption of a diet in which the indigestible residue is reduced to a minimum.

Osteitis Deformans Treated with Parathyroid Extract—Colt and Lyall report a case of osteitis deformans in which the administration of parathyroid extract caused consolidation to be rapid and the repair of the fracture to undergo a normal course. The extract has been given in a dosage of from 5 to 10 units daily, with periods of intermission, during the past two years. Acid sodium phosphate well diluted in water, was given three times a day in 1.95 Gm doses as an adjuvant to depress the absorption of calcium in the intestine, to decrease the calcium content of the serum and to promote the excretion of calcium in the urine. Sodium phosphate alone was found to be effective in the mobilization of deposits of calcium in a case of calcinosis. The authors had no facilities for estimating the effect of parathyroid extract treatment by a balanced experiment, but comparison of a series of roentgenograms of the head suggests that there is less calcification present in the skull than there was two years ago.

- *Subtertian Malaria Parasite of Kenya Note P. C. C. Garnham—p. 68
Xerophthalmia in Mathari Mental Hospital H. I. Gordon—p. 85
Considered Opinion as to the Best Treatment of Bilharzia Disease F. G. Cawston—p. 90

Subtertian Malaria Parasite—Garnham states that the Kenya subtertian parasites frequently appear as large nonanular bodies occupying from one fourth to one half of the red blood cell. Classic ring forms (when present) eventually grow into bodies in the peripheral blood in all instances. Pigmented parasites are not uncommon in the peripheral blood. The color of the pigment is primarily yellow. It becomes circumscribed in a definite vacuole. An accolé phase (peripheral adherence) may develop late in the cycle and is followed in typical cases by a nonparasitic interval. Maurer's clefts are constantly found in the infected cells, which are often slightly enlarged and paler than normal. Schizonts are fairly common in nonmalignant active cases of the disease. Schizonts are larger than usual, sometimes even filling the red blood cor-

puscles. Crescents possess a well defined peripheral thickening or ectoplasm, both in the mature and in the developing stage. The half grown gametocyte is accompanied by a curious object—a single bar (later curling up into a loop circle or ellipse) in the red blood cell. The cycle of the parasite occupies exactly forty eight hours. Splenic enlargement was appreciable in only about a fourth of 243 hospital cases. The characteristic features of the parasite are reproduced in subinoculation cases. The local parasite can be differentiated with certainty from the classic species and likewise from all other species of human malarial parasites, with the possible exception of *Plasmodium tenue* with which it may be identical.

*Paralysis of Recurrent Laryngeal Nerve. Survey of Two Hundred and Thirty Five Cases. A. B. Smith, V. F. Lambert and H. L. Wallace—p. 344

Paralysis of Recurrent Laryngeal Nerve—According to the survey of Smith and his associates paralysis of the recurrent laryngeal nerve occurs more frequently in men than in women in the proportion of 2 to 1. Paralysis of the left recurrent laryngeal nerve is of much more frequent occurrence than paralysis of the right nerve. Goiter is the most frequent causal factor of the paralysis in women and implicates the right nerve as often as the left. The commonest causes of the paralysis in men are aneurysm of the aorta and mediastinal tumor. In the majority of cases, paralysis of the recurrent laryngeal nerve should be regarded as a grave sign, especially in men. The majority of paralyzed vocal cords observed in this study occupied the cadaveric position. A paralyzed vocal cord irrespective of its position, may completely recover function. This occurs mainly in those cases in which no cause for the paralysis can be discovered. The original aphonia resulting from a permanently paralyzed vocal cord will ultimately show considerable improvement, and complete recovery of the voice may occur within one year.

Spontaneous Subarachnoid Hemorrhage. A. Patrick—p. 1
*Serum Treatment of Ulcerative Colitis. Note. D. Smith—p. 9
Some Aspects of Bright's Disease. N. Morris—p. 14

Treatment of Colitis—To establish sound treatment of ulcerative colitis, Smith emphasizes that the diagnosis should be based on a careful history and examination of the stools, a sigmoidoscopic examination performed without an anesthetic and with a minimum of inflation and an examination of a swab taken directly from the ulcerated or inflamed surface of the colon. During the past three years the author has treated six cases of ulcerative colitis with Bergen's serum. The patients have all been women, and the disease had been present for periods varying from six months to three years. Two were treated by intramuscular injections and four by the intravenous route. The amount of serum used varied from 15 to 50 cc in divided doses. In all six patients the loss of weight up to the commencement of treatment was 35 pounds (16 Kg) or more, and all have regained their lost weight except one who has regained 21 pounds (9.5 Kg) and is still gaining. In the intravenous method of administration the anaphylactic shock is sometimes alarming. The intravenous injection of from 1 to 2 cc of 1:1000 solution of epinephrine immediately after the serum has been given is the best method of minimizing the shock. The shock is not very distressing until 15 cc of serum is injected. When the reaction is severe it takes about an hour before the patient feels comfortable. With the intramuscular route there is practically no reaction. After preliminary preparation of the patient serum treatment is commenced with 1 cc of Bergen's ulcerative colitis antistreptococcus serum. The dose is increased gradually every day or every second day until 5 cc is reached. As improvement proceeds the time interval between the injections can be increased although not more than three days should be allowed to elapse as the shock is more profound after a longer interval. The shortest period of time required for clinical cure has been

nine days, and the longest thirty-six days. This does not represent the length of time required to bring the patient to a state of physical fitness but only the length of time necessary to check the diarrhea. The author has seen these patients regularly over periods ranging from six months to three years, and so far no relapses have occurred.

Influenzal Virus—Smith and his associates describe a disease of ferrets produced by the intranasal instillation of filtrates of throat washings obtained from patients with influenza. The disease is transmissible serially in ferrets either by contact or by the intranasal instillation of virus-containing material. So far the infective agent has been recovered only from the nasal passages of ferrets. The disease was produced by five of the eight throat washings obtained from patients with influenza in the early stages of the disease. Throat washings from healthy persons and convalescents from influenza caused no illness. The nasal secretions from a subject with a severe common cold caused no illness. Human serum particularly those from convalescents from influenza, were found to contain antibodies capable of neutralizing the virus of the ferret disease. Swine influenza virus caused a disease in ferrets which was indistinguishable from that produced by virus of human origin and the pig and human viruses have close antigenic relationships. The authors suggest that there is a virus element in epidemic influenza, and they believe that the virus is of great importance in the etiology of the human disease. This view receives considerable indirect support from the fact that Shope found that the pig virus was the essential factor in influenza of swine. The epizootic disease could be produced only by combining two separate agents (1) a virus and (2) *Haemophilus influenzae* (suis). The virus alone produced a disease so mild that it was difficult to recognize, and the bacillus alone appeared to be harmless. The authors' results with ferrets are consistent with the view that epidemic influenza in man is caused primarily by a virus infection. It is probable that in certain cases this infection facilitates the invasion of the body by visible bacteria giving rise to various complications. Analogous examples of this type of double infection are seen in epizootics of influenza in swine and of distemper in dogs. Decisive evidence on this point can be secured only by intensive study during an epidemic of influenza since direct experiments on man are fraught with difficulties.

Harmine Derivatives in Angina Pectoris—Bramwell and his associates point out that drugs may be used in angina pectoris to cut short the attack or to forestall individual attacks by

giving the drug a few minutes before an attack is expected, or to reduce the frequency and severity of attacks by continuous treatment. The authors shortened the attacks of angina pectoris in two patients by giving them one-half gram (0.032 Gm.) of harmol hydrochloride by subcutaneous injection. Similar relief can generally be obtained from the use of glyceryl trinitrate or amyl nitrite, procedures that are simpler and more practicable than subcutaneous injection. The authors compare the potency of the harmol derivatives with that of the nitrites, which are known to be of value in forestalling attacks. They have studied the effect of continuous treatment with harmol hydrochloride by mouth in forty-one cases of angina. In only seven was there any evidence that the patient derived benefit from the drug. Except in a single instance, no toxic symptoms were observed with harmol hydrochloride in doses of 2 grains (0.13 Gm.) or less by mouth three times a day, though larger doses were liable to give rise to epigastric discomfort, anorexia, nausea, vomiting, lack of energy, palpitation and occasionally diarrhea. Acute attacks of renal colic occurred in three patients who were taking large doses (from 4 to 5 grains [0.26 to 0.32 Gm.] three times a day). The authors also treated twenty patients continuously with O-*n*-propylharmol lactate by mouth. Four patients treated soon after the onset of angina appeared to derive benefit from this drug, but no improvement was observed in the more severe type of angina. The dose did not exceed 1 grain (0.065 Gm.) three times a day.

Injection of Sodium Nucleinate—Jono observed that the chief biologic reactions produced by the intravenous or the subcutaneous administration of sodium nucleinate to human beings or animals are (1) marked lowering of blood pressure, accompanied by dyspnea and, in some cases, convulsions, (2) occurrence of initial leukopenia followed by leukocytosis (3) increase in blood coagulation, (4) decrease in the carbon dioxide content of blood plasma, (5) descending velocity of erythrocytes quickened in the case of small doses but delayed when a large dose is administered, (6) reduction of blood viscosity and serum protein content, and (7) marked increase in blood sugar content. When sodium nucleinate is given by mouth, no change takes place in the blood pressure or in the number of leukocytes and their nuclei. The effects produced on the blood pressure and leukocytes when sodium nucleinate is injected

directly into the portal veins are similar to those in intravenous administration, but a much smaller dose is sufficient to bring about the effect, and to a more marked degree. In ascites due to congestion of the portal vein, the existence of nucleic acid was not demonstrable, either directly or indirectly. From these results the author deduces that the biologic reactions produced by the injection of sodium nucleinate may be explained as an allergic reaction and that in the healthy body sodium nucleinate which reaches the intestine does not enter the portal veins but is decomposed to some degree in the intestine or its walls and absorbed.

Comparative Study of Antidiphtheritic Serums of Paris and Brussels G. Ruelle—p. 1383
*Interpretation of Negative Cholecystogram P. Buisson—p. 1386

Prognosis of Malignant Lymphogranulomatosis—Of eighty patients with malignant lymphogranulomatosis observed by Goia since 1920, the seventeen patients still living and forty-six of those deceased received roentgen therapy. The average period of survival after the appearance of the first symptoms is five years and four months for the former group, two years and three months for the latter group and three years and one month for the two groups collectively. This compares favorably with the average of seven months for those who received no treatment at all and shows that roentgen therapy is capable of extending the duration of life for a few years. The therapeutic results of roentgen therapy depend primarily on the form of evolution of the disease. In rapid, acute cases, the effect of roentgen therapy is mediocre or absent and occasionally disastrous. In apyretic, slowly evolving cases roentgen therapy may achieve good results depending on the location of the lesion and the stage of the disease. So far as prognosis is concerned the signs indicating a malignant evolution are the involvement of several lymph nodes in rapid succession, the involvement of internal lymph nodes, especially the retroperitoneal and mediastinal lymph nodes, the occurrence of visceral lesions simultaneously or soon after the appearance of adenopathies, multiple gastro-intestinal ulcerations, constant high fever and resistance to roentgen therapy. The disease usually lasts only a few months after the onset of pleurisy, pulmonary lesions on the other hand, are less grave and often respond well to roentgen therapy. An adenopathy that remains localized a long time usually indicates a more benign evolution. A visceral lesion may remain benign a long time if it constitutes the first manifestation of the lymphogranulomatosis, but it assumes a malignant character when the lymph nodes also become involved. Lymphogranulomatosis of the mesenteric lymph nodes has a less grave prognosis than that of the other internal lymph nodes, and lymphogranulomatosis of the mediastinal lymph nodes sometimes responds well to roentgen therapy. Isolated tumors of the gastro-intestinal tract are relatively benign and sometimes well adapted to surgical intervention. A rapid regression of the lymph nodes and the spleen in response to roentgen therapy indicates a benign evolution. Hematologic signs have some prognostic value in association with other signs. Leukocytosis, if constant, and spontaneous constant leukopenia are grave signs, but leukopenia in response to irradiation is a favorable sign. Neutrophilia neutropenia combined with leukocytosis, and monocytosis combined with leukocytosis are signs of a rapid evolution. An eosinophil count of over 15 per cent and a platelet count of from 700,000 to 1,000,000 are found in the grave forms.

Interpretation of Negative Cholecystogram—Buisson states that invisibility of the gallbladder in cholecystography after intravenous injection of the contrast medium is a pathognomonic sign of a pathologic process directly involving the hepatobiliary system. In 650 cholecystographies he obtained negative pictures only in cases in which there was an important lesion of the biliary tract or the gallbladder itself. This contradicts the assertions of other authors that disease processes not directly involving the hepatobiliary system, such as duodenal ulcer or appendicitis can prevent visualization of the gallbladder. Negative cholecystograms were obtained by the author in all cases of (1) chronic sclero-atrophic cholecystitis, (2) chronic

suppurative cholecystitis, dropsy or empyema of the gallbladder, (3) occlusion of the intrahepatic or extrahepatic bile ducts, whether due to calculi lodged in the ducts, neoplastic nodules, parasites from the duodenum or inflammatory processes of the ducts themselves, and (4) stenosis of the ducts or virtual suppression of the gallbladder due to adhesions, scars, adenitis and so on. Negative cholecystograms in patients with disease outside the hepatobiliary tract were obtained by the author only in cases in which intervention also demonstrated one of the forms of hepatobiliary lesion previously mentioned. Positive cholecystograms were obtained in cases of cholecystitis, biliary lithiasis and pericholecystitis not of the aforesaid types, in congenital morphologic anomalies of the gallbladder and in many cases of hepatic disease, even grave and rapidly fatal cases. The negative cholecystograms of other authors can be explained only through the following errors of technique or interpretation: (1) failure to give the iodine compound intravenously or to give a sufficient quantity, (2) failure to fast from six hours before injection to the completion of the cholecystogram, (3) too rapid filling of the gallbladder in patients with cirrhosis, hyperthyroidism or gastro-enterocolic hyperkinesia, (4) retarded filling of the gallbladder in patients with excessive dehydration, (5) weak or transitory filling of the gallbladder due to excessive dehydration or excessive hydration, (6) unusual location of the gallbladder and (7) existence of a lesion of the biliary tract which cannot be diagnosed at surgical intervention.

Measuring Superficial Temperature by Means of Dermatherm of Tyco. A. Chasserini—p. 1497.

Influence of Malaria on Course of Diabetes.—Guglielmo observed two patients suffering from diabetes, who years later contracted malaria. One had a history of successfully treated syphilitic infection acquired before the malaria. After six months of malarial treatment with quinine compounds, the two were cured. During this period neither glycosuria nor glycemia was present. Some months after treatment, the glycosuria was about 40 per thousand and the hyperglycemia (on an empty stomach) 145 per thousand. One patient showed no diabetic manifestations for one and a half years, finally becoming diabetic again. The other died soon afterward from bronchopneumonia. The author does not attribute this temporary cure of diabetes to the antisyphilitic treatment in one patient or to the action of the quinine in both. He does not believe that the malarial parasite exerts a beneficial action on the pancreatic or hepatic cells, but he concludes that malaria influences the course of diabetes through the mechanism of its pyrexia.

- *Von Brugsch Reaction in Jaundice of the New Born. J. Carrera Portela—p. 337.
Schwenker's Treatment in Grave Forms of Diphtheria. F. Cirajas—p. 351.

Von Brugsch Reaction in Jaundice of the New-Born.—Carrera Portela states that von Brugsch claims that his reaction, the positivity of which is indicated by a blue discoloration of the skin following the intradermal injection of a small amount of a 1 per cent solution of potassium ferrocyanide is of value in making a pathogenic classification of certain types of jaundice. He distinguishes four different shades of icteric pigmentation (reddish yellow, greenish yellow, light yellow and amber yellow) which he correlates respectively with the hepatotoxic obstructive hemolytic and chronic forms of jaundice. The fact that the reaction always gives positive results in those types of jaundice which present a pigmentation of a dark orange-reddish hue has led this author to interpret them as an indication of insufficiency of the liver. Dietrich investigated von Brugsch's theory and came to the conclusion that the blue reaction is not related to the cause of the disease but rather to the intensity of the bilirubinemia. The author likewise investigated the prob-

lem and his observations corroborate Dietrich's claims rather than von Brugsch's. He reports the results of the test in fifty-three new-born infants with jaundice of the new-born. The test gives positive results more frequently in younger than in older infants. The positivity of the test diminishes as the infant grows older. Various hues of yellow are shown in the same type of jaundice, whether of physiologic or of syphilitic origin. The orange and reddish hues predominate in cases of jaundice in younger infants and become of a lighter color as the infant grows older. The distribution and intensity of the pigment, the previous presence of icterogenic erythrodermia and the intensity of this erythrodermia do not influence in any way the results of von Brugsch's reaction. Regardless of the type of jaundice, the results of the test are positive when the pigment presents an orange-reddish hue, otherwise they are negative. The factor of primal importance in the results of the test is the color of the pigment. The author performed the reaction twice in two infants who presented a light pale pigmentation the first time the test was made. In the infant in whom the pigmentation was of a pale hue both on the first and on the second time the reaction was performed, the results of the test were negative. In the infant who had a light pigmentation when the test was performed for the first time and in whom the pigmentation changed to a darker hue, the results of the test changed from negative in the first reaction to positive in the second. The author concludes that the reaction will give positive results in all types of jaundice as long as the dark orange-reddish color predominates and that these results do not indicate the cause of jaundice but rather the intensity of the bilirubinemia.

Suppurative Endomyometritis as Cause of Rupture of Uterus.—Friedrich reports the history of a woman, aged 39, who died less than two hours after delivery. The case was at first diagnosed as acute cardiac insufficiency during delivery, but the postmortem examination revealed a spontaneous rupture in the lower part of the uterus and in the upper part of the cervix. The microscopic examination of the uterine wall disclosed an extensive suppurative endomyometritis which probably developed shortly before delivery by an infection from the outside and led to a severe injury of the uterine wall particularly in the region of the isthmus. The author considers the fact that the insertion of the placenta reached partly into the isthmus, a contributing cause of the rupture. Other factors that could have played a part in the pathogenesis of the spontaneous rupture were not present.

Interruption of Pregnancy During Pulmonary Tuberculosis.—After pointing out that opinions about the influence of pregnancy on pulmonary tuberculosis differ widely, Glaser

reports his own observations. Statistical reports show that the course of pulmonary tuberculosis is not more favorable in case of interruption of pregnancy than if it is carried to term. The author's own observations convinced him that pregnancy and delivery have no noticeable influence on the course of the pulmonary tuberculosis. However, in some women an exacerbation of the tuberculous process sets in after delivery. The first six months has been referred to as the "critical half year." During this period, institutional therapy is advisable. The author evaluates the reasons cited in favor of interruption of pregnancy in tuberculous women, and for the majority of cases he does not recognize as valid the medical, the social or the eugenic indications. He demonstrates the necessity of treatment for tuberculous pregnant women; he discusses the course of pregnancy, delivery and puerperium of women in whom collapse therapy has been resorted to and he directs attention to the possibility of reciprocal modification. He gives a tabular report of the results obtained with collapse therapy in tuberculous pregnant women in recent years. From the favorable results of a suitable treatment the demand is deduced to reject interruption of pregnancy in all women in whom the tuberculosis can be treated but in whom treatment has not yet been instituted. Occasional exceptions that justify an abortion are conceded. The author thinks that new pregnancies are undesirable before permanent cure has been obtained but he considers sterilization justified only in exceptional cases.

Differentiation of Hormonal Substances—Kleine and Paal show that the positive acetonitrile reaction (protection against acetonitrile) is not strictly specific for the presence of thyroidal substances, because partial protection could be obtained with tyrosine, with an ovarian preparation, with carbohydrates and with their products of disintegration. However, by means of the so-called transmitted reaction, the acetonitrile test could be made more specific. When normal rabbits were given three injections of dextrose solution, of the ovarian extract or of tyrosine their blood serum gave a negative acetonitrile test twenty-four hours after the last injection. This transmitted reaction improved the diagnostic value of the acetonitrile test. The authors report their studies on a preparation of the posterior hypophysis, on epinephrine, on various ovarian hormones and particularly on fluids from ovarian cysts. They conclude that 1. The preparation of the posterior hypophysis gives a positive acetonitrile test, but hydrolysis in the oxygen stream destroys the protective action against acetonitrile. In contradistinction to the thyrotropic substance of the anterior hypophysis, the preparation of the posterior hypophysis does not produce a histologically demonstrable activation of the thyroid. 2. A positive acetonitrile test can be produced with epinephrine. However, in contradistinction to the posterior hypophyseal extract, to the thyrotropic substance of the anterior hypophysis, to thyroxine and to folliculin, epinephrine shows no protective action against acetonitrile in the transmitted reaction. The histologic test reveals no thyroid activation. 3. Folliculin gives a positive acetonitrile test and this protective action against acetonitrile is not destroyed by hydrolysis in the oxygen stream. The histologic test shows no thyroid activation. 4. Fluids from nonblastomatous follicle cysts produce positive acetonitrile reactions. These positive reactions are probably due to the presence of folliculin, for the positive estrus reaction, in one instance and also the persistence of positivity of the acetonitrile test following hydrolysis in the oxygen stream seem to indicate this. 5. Cystic fluids from benign and malignant epithelial ovarian blastomas produce positive acetonitrile reactions. These positive reactions are probably partly the result of the presence of anterior hypophyseal substances, for in one instance the Aschheim-Zondek reaction I was positive, but they must be due also partly to the presence of folliculin (positive estrus reaction). 6. Cystic fluids from pseudomucin cystomas can produce positive acetonitrile reactions. In these cases they are probably caused by the presence of folliculin since one case gave a positive estrus reaction. 7. Cystic fluids from ovarian dermoids give positive acetonitrile tests, and here again the presence of folliculin seems responsible, since here too the estrus reaction was positive. 8. Cystic fluids from parovarian cysts give positive acetonitrile reactions but in this case the positivity must be the result of substances from the anterior hypophysis, for the estrus reaction was negative.

*New Method for Quantitative Histidine Determination and Its Application in Examination of Biologic Fluids Particularly of Urine from Pregnant Women R. Kapeller-Adler—p. 131

Determination of Histidine in Urine of Pregnant Women—Kapeller-Adler describes a new method for the colorimetric determination of histidine. Histidine, when brought carefully into reaction with a solution of bromacetic acid, and after that with an ammonia ammonium carbonate mixture assumes, when heated, a deep blue-violet color. The sensitivity of this reaction is 1:50,000. Compared to other methods for the determination of histidine, this method has the advantage that it is specific for histidine, for even the closest derivatives of histidine do not give this reaction. Histamine gives a positive reaction, consisting of an extremely weak gold yellow coloration and methyl-histidine gives a slight red-violet coloration. The author has perfected the method for the quantitative determination of histidine in biologic fluids, particularly in urines. Tests were made on urines from normal men and women, from pregnant and puerperal women and from persons with various disorders. It was found that the urines from pregnant women always contained histidine in smaller or larger quantities (from 6 to 74 mg. per hundred cubic centimeters, and sometimes as much as 800 mg. in the daily quantity of urine).

*New Rapidly Curative Method of Acute and Chronic Uncomplicated Gonorrhea in Men H. Tischler—p. 1265

Treatment of Gonorrhea in Men—Tischler employs a bacteriolytic, which acts specifically on gonococci and which does not irritate the most sensitive urethra. In anterior gonorrheal urethritis his method is as follows. After urination, the urethra is irrigated with a permanganate solution of 1:10,000. This irrigation has the object of eliminating the coating of pus. Then a strip of medicated gauze, from 1 to 2 cm. in width and slightly longer than the anterior urethra, is saturated with the antgonococcal bacteriolytic and introduced by means of a hollow sound. A little more of the bacteriolytic is added, so that the gauze strip is well saturated. To facilitate the introduction of the gauze, liquid petrolatum is applied both to the end of the gauze strip and to the sound. The author advises that the urethra of sensitive patients be anesthetized with a 5 per cent solution of procaine hydrochloride and, in order to avoid unnecessary irritation, that care be taken that the sound does not advance up to the external sphincter. Dry cotton is applied and fixed by means of adhesive tape to the end of the gauze strip protruding from the urethra. The patient is advised to limit his water intake so as to avoid frequent micturition, in order to retain the gauze strip for a comparatively long time, if the treatment is given in the evening it can be retained until the next morning. The treatment is repeated daily, and patients who have had several attacks of gonorrhea may be treated twice daily. In total gonorrheal urethritis the treatment is similar to that of the anterior form. The introduction of the gauze strip is tolerated even in epididymitis, but the treatment is not advisable in cases of complication with cystitis and acute prostatitis. The advantages of the author's method are that it shortens the time of treatment and that the gauze strip effects drainage of the urethra and prevents the development of a stricture. Moreover the urethra retains its former elasticity and its epithelium does not undergo such changes as are frequently observed following the use of silver solutions.

*Poliomyelitis in Adults F Nagel — p 1328
*Treatment of Acute Anterior Poliomyelitis by Means of Blood Transfusion from Convalescents I Sherman — p 1332

Nerve Stretching Reflexes—Feureisen aims to determine whether Kehrer's nerve pressure or nerve stretching reflexes indicate an increase in intracranial pressure or a cerebral swelling, or whether they merely indicate a more or less diffuse, latent hyperalgesia. The reflexes are elicitable by pressure on or stretching of nerve trunks, particularly at the sites of exit of the trigeminal and occipital nerves. In a large percentage of patients with brain tumor, Kehrer's reflexes were positive but there were some cases of brain tumor in which these reflexes remained negative. Recently however, the author observed in a patient who had a tumor of the frontal lobe that proved inoperable but could be favorably influenced by roentgen treatment that pressure on the trigeminal points produced an intense pain reflex while the patient was lying down, whereas the reflexes could not be elicited when he was sitting up or standing. This observation differentiates Kehrer's reflexes from Vallier's pressure points observed in neuralgias, neuritides and hyperalgesias. The author admits that only some of the patients with brain tumor showed this change in the reflexes in different positions. In some patients there were no changes, while in others the reflexes were negative in the reclining position and positive in the erect position. In other patients, the reflexes showed the same behavior as in the described case. The first observations seemed to indicate that tumors in the anterior cranial fossa cause an intensification of Kehrer's reflexes when the patient is reclining, while tumors in the posterior cranial fossa cause an intensification when the patient is standing. Later observations did not corroborate this assumption, but the author thinks that the fluctuations in intensity resulting from positional changes do nevertheless increase the diagnostic value of Kehrer's reflexes and for cases in which such fluctuations are observable he accepts Kehrer's maxim: "If a patient presents exclusively or predominantly signs of an organic lesion of the brain and in spite of prolonged rest in bed persists in showing the pain reactions of the trigeminal and occipital nerves, an intracranial pressure increase or a swelling of the brain exists and if there are no signs of meningitis and toxic causes cannot be found a brain tumor exists." Another aid in differentiating Kehrer's signs from mere hyperalgesic pressure points is the strong pain (evasion) reflex that becomes noticeable although the patients assert that the pressure did not cause pain.

Poliomyelitis in Adults—Nagel's observations during the epidemic of poliomyelitis in Leipzig in 1932 showed that about 15 per cent of the patients were adults and that the adults contracting the disease were in greater danger since their mortality rate was much higher than that of children. The author was unable to corroborate the observation that adults show more often an atypical course of poliomyelitis than do children; he found manifold symptomatology but not more so than in children. He gives an outline of the typical course of the disease which he thinks will aid in the diagnosis during the preparalytic stage and he advises that even slight meningeal symptoms should be given careful consideration but he does not think that the examination of the cerebrospinal fluid is of value for the differential diagnosis nor does he consider the number of cells in the cerebrospinal fluid and the first extension of the paralysis a reliable basis for the prognosis. In discussing the treatment the author mentions the various forms of serotherapy, the use of horse serum as well as of convalescent serum and the intramuscular, intravenous and intraspinal administration. He shows how widely opinions differ in regard to the efficacy of serotherapy and he cites one statistical report

demonstrating conclusively that after serotherapy the incidence of paralysis as well as the mortality rate is higher than in cases in which serum is not employed. In view of his own experiences with serotherapy, he thinks that intramuscular or intravenous injections of serum or blood may perhaps be tried, but he advises against intraspinal injection of serum. He thinks that physical therapy is helpful for the improvement of impaired muscles.

Treatment of Acute Anterior Poliomyelitis—Sherman treated fifty-five patients having acute anterior poliomyelitis by means of convalescent serum. The serum was administered intramuscularly or intraspinally, and the quantities varied between 50 and 100 cc. Since the results of this serotherapy were not entirely satisfactory, he decided to employ transfusions of blood from convalescents, reasoning that thus the blood is fresh and unchanged that it can be given in larger quantities than the serum and that it is possible that the protective power of the whole blood is greater than that of the serum. Transfusion of blood from convalescents was resorted to in seventy-one cases. The smallest quantity of blood given was 150 cc while some patients received as much as 400 cc. A comparison of the results of the serum therapy with those of the blood transfusions demonstrated the superiority of the transfusion method. Not only did the transfusion reduce the mortality rate and the frequency of paralysis but its efficacy was demonstrated particularly in the course of the fever and in the general symptoms of the acute infectious disturbance. He suggests that health organizations should keep a record of donors, so that they will be available at any time.

So-Called Glycolysis of Blood—Loewenstein and Botstiber point out that for serial determinations of the blood sugar the method of Hagedorn-Jensen has been considered the best, because in this method the blood can be kept for several hours in a solution of zinc hydroxide, and thus it is possible to analyze several specimens together. The authors, however, noticed certain irregularities that induced them to determine whether the blood specimens brought in the solution of zinc hydroxide really retain their original sugar content. They were able to show that even in the micromethod of Hagedorn-Jensen there develops "glycolysis" or rather a diminution of the reduction capacity of the blood, unless the blood is completely deproteinized immediately following its withdrawal. The diminution is greatest after about three hours. The reduction is partly reversible, and it is more pronounced in the blood than in the serum. This glycolysis or diminution in the reduction capacity predisposes to errors particularly in the serial determinations during tolerance tests.

Posterior Lobe of Hypophysis and Eclampsia—Ohligmacher mentions a number of authors who assumed a relationship between the posterior lobe of the hypophysis and eclampsia. He calls attention particularly to Fauvet's studies reported in the *Klinische Wochenschrift* (10 2125 [Nov 14] 1931) abstr. THE JOURNAL Jan 23 1932 p 358. In this report Fauvet shows that the anatomopathologic changes typical for eclampsia

can be produced in animals by the injection of the hormones of the posterior hypophysis. Because of the great importance for the problem of eclampsia, the author decided to repeat these experiments. In spite of resorting to varying dosages and periods of injection and although he made the experiments on animals from various litters and on pregnant animals and on males, he never was able to produce the necrotic foci in the liver and the other changes described by Fauvet. He concludes that the theory of the role of the posterior hypophysis in the pathogenesis of eclampsia cannot be considered proved but that, like most other theories on eclampsia, it is still an open question.

Development of Antrum Gastritis—Overgaard reports experiments on dogs. One group was given daily histamine injections while the stomach was empty, so that the gastric juice that was secreted under the influence of the histamine could influence the mucous membrane for some time and in these animals considerable inflammation resulted. That these inflammatory changes were not produced by the histamine injection as such but rather by the gastric juice secreted under histamine action is proved by the fact that dogs fed immediately after the injection did not develop such inflammatory changes. In order to establish still more conclusively that the changes were the result of the action of the strongly acid gastric juice, a number of animals were given a solution of hydrochloric acid by means of a stomach tube. The concentration of the solution corresponded to that of the gastric juice secreted under histamine action. The dogs treated with the solution of hydrochloric acid likewise developed gastric symptoms. In some of the animals treated with a somewhat different technique, ulcerations developed in the stomach and the duodenum and their histologic structure resembled the ulcers developing spontaneously in human beings. The microscopic studies convinced the author that acute inflammatory changes develop in the gastric mucous membrane if it is exposed for longer periods to the influence of a strongly acid undiluted gastric juice. These gastric changes resemble greatly those observed in antrum gastritis in human subjects.

Acute Benzene Poisoning—Schneider observed a youth, aged 17, who, while lifting a hose filled with benzene, got a gush of it into his mouth and probably swallowed some of it. He immediately felt pains in the chest and became dizzy. The gastric contents, when pumped out two hours later, had no benzene odor. The pains in the chest increased particularly on the right side, and severe palpitation of the heart set in. The following morning the pains were so severe that he could hardly breathe, and he was hospitalized. On the right side, beginning with the fifth rib, there was decreased resonance and the respiration was weakened. Examination of the urine revealed albuminuria increased urobilinogen and cylindruria. The hemogram disclosed a leukocytosis, and the author thinks that this as well as the fever were secondary changes and the result of the pulmonary symptoms. The thoracic pains and the pulmonary symptoms were most likely caused by a hemorrhagic focus near the diaphragm and by an involvement of the bronchus. The hemorrhagic character is assumed on the basis of observations in other cases. It is likely that the fright from the sudden gush caused the aspiration of some of the fluid benzene. The patient recovered within a month. The favorable course and rapid

recovery indicate that the patient absorbed only a small quantity of benzene, and for this reason the suddenness and the severity of the pulmonary symptoms are the more surprising. The author thinks that the fact that the accident happened shortly after the patient had eaten a heavy meal and the tendency of benzene to combine with fats were important factors in this case, for it has been shown in animal experiments that an increased fat content of the blood makes for a greater susceptibility to benzene.

Differential Diagnosis of Appendicitis—Berner calls attention to an anomaly in the intestinal tract that may lead to an incorrect diagnosis of appendicitis and of ulcer of the stomach or duodenum. He describes his observations on a man, aged 33. There was tenderness at McBurney's point but no vomiting or constipation and the hemogram was normal, at any rate there was no leukocytosis. Roentgenoscopy of the intestinal tract disclosed that the appendix was on the left side. Examination of the upper portion of the intestinal tract following a contrast meal revealed that the duodenum took a normal course to the papilla but then turned to the right, backward and upward. The duodenojejunal flexure was absent and the jejunal loops were nearly all in the right side of the abdomen, only the terminal portions of the ileum were in the middle of the abdomen and the cecum was on the left side. The author thinks that the anomalous course of the duodenum and the fact that most of the loops of the small intestine were on the right side demonstrate a malformation of the mesentery, caused by an incomplete torsion of the root of the mesentery during the embryonal period. He calls attention to other reports on this anomaly and emphasizes the dangers to which such patients may be exposed if the anomaly is not recognized. He considers it advisable to inform the patients that they have the anomaly.

- Diagnosis of Latent Phlebitis in Lower Extremities O. Meyer — p. 1297

Pernicious Anemia and Pregnancy—Eydling relates the histories of two women with pernicious anemia, in whom liver therapy, particularly by injection, had produced remissions and who later became pregnant. The pregnancy took a normal course in both women and the infants were healthy. The author calls attention to the fact that, since the introduction of liver therapy, the unfavorable influence of pernicious anemia on pregnancy does not have to be feared as much as formerly. He thinks that interruption of pregnancy is not necessary, if it is possible to produce remission by means of liver therapy, and that suitable treatment and constant hematologic control will protect the mother from grave dangers. Since in the reported cases the infants did not show abnormal blood pictures, the author thinks that the prognosis for the life of the infant has also become more favorable by the maternal liver therapy.

Ointments and Cosmetics Containing Cholesterol—Moncorps and his associates investigated (1) the occurrence of ergosterol or vitamin D in ointments and cosmetics that contain cholesterol, (2) the possibility of percutaneous absorption of vitamin D, and (3) the quantitative ratio between supply and intake in percutaneous administration. In studying the occurrence of ergosterol in ointments containing cholesterol, they studied particularly anhydrous wool fat. The presence of ergosterol was detected and by means of ultraviolet irradiation this ergosterol could be transformed into vitamin D. The possibility of percutaneous absorption of vitamin D was proved in anatomic and therapeutic studies on animals. The anatomic studies revealed that cholesterol ointment and to a lesser degree also irradiated wool fat, produce pathologic changes on the vessels and the internal organs that are identical with those following oral poisoning by vitamin D. The therapeutic experi-

ments showed that rats with rickets could be cured by irradiated wool fat. In regard to the quantitative problem, the authors express the opinion that it is not likely that the derivatives of wool fat used for therapeutic or cosmetic purposes, including hair tonics containing cholesterol, have a detrimental effect on the health, especially if a transformation of ergosterol into vitamin D by irradiation is avoided, but that in extreme cases an injurious result is possible. They consider it entirely wrong to recommend a skin cream that contains irradiated ergosterol as a cosmetic and a protection against sunburn, because this substance is a potent therapeutic agent and not a cosmetic the use of which can be recommended to every one.

Histogenic Antibodies in Allergic Skin Diseases—Perutz emphasizes that, in order to classify a skin disease as an allergoderma, three points have to be proved: (1) the specificity of the hypersusceptibility, (2) the possibility of experimental sensitization, and (3) passive transmission of the allergy. He reviews the literature. The opinions of the investigators are divided as regards the passive transmission of allergy. He shows that the cellular localization of the allergy has been demonstrated, that it has been possible to transmit the allergy to a healthy individual by means of the serum of a susceptible individual, and that with the aid of this method it has been possible to identify a number of disturbances as allergic. He considers the problem of passive transmission largely solved, but, to demonstrate the antigen-antibody character of the transmission more clearly, he devised a control reaction. The reacting body belongs to the group of thermolabile substances, because, whereas the passive transmission of the normal content of a blister gave a positive result, transmission proved impossible after the content of the blister had been inactivated by heating and keeping it at a temperature of 55 C for half an hour. The author suggests that in passive transmission experiments the active as well as the inactivated content of a blister should be injected, and that then the allergen should be applied. Only the site that has been treated with the active content of a blister, but not the one that has been treated with the inactivated content should react to the allergen application with eczematous manifestations.

Treatment of Juvenile Uterine Hemorrhages—Heynemann emphasizes that in cases of extragenital origin, that is, when the uterine hemorrhage is the result of cardiac, vascular, renal, pulmonary, or hemopathic conditions, it is necessary to treat the underlying disease. He thinks that further research will probably disclose that functional disturbances of the blood are more often the cause of the severest uterine hemorrhages than was formerly assumed. Although comparatively rare in young girls, the possibility of the presence of genital tumors

and polyps should not be overlooked as a cause of hemorrhages. In other cases the hemorrhages are generally of endocrine origin, and for these hormone therapy seems indicated. However, the results heretofore obtained with hormone treatment have not been entirely satisfactory. The author thinks that, although the knowledge about the numerous hormones is not complete, there are certain pointers that should be followed. In menorrhagia he strives to effect improvement by general measures, particularly when the patient is weak and undernourished. If this is not the case and the rectal gynecologic examination reveals no abnormality, uterus-contracting medications should be given during the bleeding, and follicular hormones could be administered between the menstrual periods. If there is a noticeable, genital hypoplasia, a preparation of the anterior hypophysis may be tried. Menorrhagia may also occur in young girls in whom the extragenital endocrine glands do not function properly. The glands most frequently involved are the thyroid and the hypophysis. If hypofunction of the thyroid exists, thyroid extract should be given, but if there is hyperfunction, suitable internal or surgical measures should be resorted to. When menstruation is greatly prolonged, glandular hyperplasia may be the cause. In young girls with this complaint, curettage occasionally became necessary, but the author thinks that, in the future, treatment with the new corpus luteum hormones and the B preparations of the anterior hypophysis may replace curettage. The author advises that roentgen and radium therapy be avoided as much as possible, however, if all treatments should fail, he considers a temporary exclusion of the ovarian function by roentgen rays preferable to extirpation of the uterus. He thinks that the prognosis of juvenile uterine hemorrhages is more favorable today than it was formerly.

Conception Following Treatment for Inflammation of Adnexa—Of a large number of women who had undergone a conserving operation, Hübscher reexamined 102. The surgical treatment was confined to the removal of adhesions or to the extirpation of one tube or of one ovary, which in some instances was combined with salpingostomy. He found that conception had taken place in 137 per cent, and, when those were subtracted who had undergone salpingostomy (which he considers useless), the incidence of conception was 23 per cent. Of the women who had received only conservative treatment, 133 could be reached for an after-examination. Of these, 256 per cent had become pregnant again. From these comparatively low percentages the author concludes that the prospects for a later conception are not favorable after inflammations of the adnexa. To what extent newer methods of treatment will improve the prognosis for later pregnancies the author is unable to determine, but he thinks that in view of the anatomico-pathologic behavior of the tube after an inflammation the prospects are not favorable.

Air Test to Determine Completeness of Placenta—Richter mentions the methods that have been recommended for testing the completeness of the placenta. He tried Franken's air test on 250 placentas. The placenta, held by the umbilical cord, is put into a wash basin that contains warm water. Then air is introduced slowly through the umbilical vein by means of a syringe of 200 cc capacity. From 150 to 200 cc is sufficient for most placentas, however, if a greater quantity is required, the syringe is refilled and more air is introduced. The author points out that even the inspection under water has advantages over the ordinary inspection, in that, without injury to the tissue the blood coating is removed and the decidua becomes plainly visible as a grayish membrane, and defects in the pink chorion tissue are more easily recognized not only because of the greater contrast but also as a result of the inflation of the placenta. The slightest injury of the chorionic tree opens the placental circulation and air bubbles rise to the surface. The size of the air bubbles should be taken into consideration. If only small bubbles develop the tears are merely superficial and do not necessitate an intervention. In evaluating the results obtained with the air test on the 250 placentas examined he points out that the air test (like the tests that employ other mediums for filling) indicates only an injury of the chorionic tree but not a loss of villous tissue. Consequently, a careful inspection should always be

combined with it. Together the two methods are much more reliable than inspection alone. He thinks that the test should find a wide application in view of its simple technique.

*Clinical Picture and Therapy of Rhinoscleroma. A. Dobrzanski—p. 700
Mutability of Rhinoscleroma Bacillus. Preliminary Report. H. Meisel and E. Mikulaszel—p. 703

Treatment of Rhinoscleroma.—Dobrzanski states that rhinoscleroma gives a characteristic clinical picture. On the few occasions in which it is difficult to diagnose the decision should be aided by bacteriologic, serologic, respiratory and blood tests together with a biopsy. It is curable in all instances except badly neglected cases presenting profuse cicatrices and growths together with rhinoscleromatous changes in the lower part of the trachea and in the bronchus that bring about the suffocation of the patient. Rhinoscleroma demands a long period of adapted and controlled treatment extending over several years. The length of treatment will have a bearing on its recurrence. The author advocates both the bloody and the bloodless operation such as diathermy and galvano-cautery in conjunction with suitable mechanical expanding pressure. Independent of this the entire respiratory tract should be submitted to roentgen irradiation beginning from the nose all the way down to the bronchi. Injections of sodium bismuth or antimony may be given and some authors state that a combination of these solutions gives good results in individual cases.

Pulmonary Tuberculosis and Syphilis. F. P. Chkalov—p. 449

Scarlet Fever and Heart Disease.—Molchanov observed seventeen instances of endocarditis following scarlet fever. The age of the patients was between 4 and 12 years. A simultaneous joint involvement was noted in fourteen patients developing endocarditis. The author is of the opinion that this type of endocarditis should be regarded as a rheumatic form as was proved in an autopsy on one of the patients. The simultaneous occurrence of endocarditis and of joint inflammation cannot be regarded as a coincidence. He concludes that scarlet fever may cause endocarditis and does so more frequently than was formerly believed. The author offers the theory that the late appearance of the rheumatic complication in scarlet fever is an allergic reaction on the part of children already predisposed to it.

*Ovarian Pregnancy. E. Thorgersen—p. 972
General Remarks on Treatment of Mental Disease with Casuistic Contribution. Treatment with Ovarian Extract, Thyroid Tablets and Compound Solution of Iodine. O. Lingjærde—p. 989
*Pneumonia with Empyema and Pyemia Due to Anaerobic Gram Negative Leptothrix. Fatal Case. T. Thjotta—p. 998

Funicular Myelosis and Pernicious Anemia.—Holst says that funicular myelosis occurs most often in pernicious anemia but may also appear in other diseases. The impression seems to be gaining that funicular symptoms in pernicious anemia are almost as frequent as gastric achylia (cf. Naegeli's pernicious triad). The spinal symptoms are often so inconspicuous as to be overlooked unless a systematic careful examination

is made at intervals during the anemia. There is no fixed relation between the symptoms of funicular myelosis and of anemia. Funicular myelosis may be an initial symptom (like achylia) followed sooner or later by anemia. In the first of the two personal cases described there were ataxia, spastic paresis and astereognosis, although the anemia had yielded to liver treatment, and in the second, after marked improvement of the anemia, there was acute onset of spinal symptoms with progression and fatal outcome. In Holst's opinion, graver cases of spinal symptoms have become more common in recent years. The anatomicopathologic changes in funicular myelosis consist of scattered degenerative foci in the white substance of the spinal cord. It is not yet definitely known, he says, to what extent liver therapy affects the myelosis, but the treatment should be instituted as early as possible and large doses should be given over longer periods. He cites the results of necropsy in two cases of pernicious anemia in which funicular myelosis was the immediate cause of death.

Ovarian Pregnancy.—Thorgersen discusses the etiology, pathogenesis and symptoms of ovarian pregnancy. He considers inflammatory changes in the small pelvis with formation of adhesions the main cause, and irregular hemorrhages and abdominal pain the most important clinical symptoms. Clinical diagnosis is impossible and even during operation diagnosis may be difficult. In the first of his two cases with ruptured pregnancy after six weeks, Spiegelberg's criteria were all fulfilled. The second patient had been sterile for eight years pointing to possible abnormal changes in the ovaries and tubes which might explain the origin of the ovarian pregnancy. In the first half of the pregnancy there were two pronounced attacks of abdominal pain with hemorrhage. Pains set in at term, but they ceased and were followed by hemorrhage, operation was done on the diagnosis of extra uterine pregnancy.

Pneumonia with Pyemia Due to Leptothrix.—In this fatal case, several bone abscesses developed. The illness lasted for five months and led to great emaciation. From pus from the empyema cavity and the bone abscesses and from the sputum, Thjotta cultivated a gram negative organism consisting of long threads without branching. The organism grew only under anaerobic conditions and particularly in dextrose broth containing sterile pieces of fresh potato, it could not be cultivated on surface mediums and is assumed to produce some substance that hinders the development of surface colonies. The organism split carbohydrates and produced abundant indole and is classified as aleptothrix. It is regarded as the undoubted cause of the disturbance; there were no other organisms in the material examined, the leptothrix was established in all the material and in pure culture and the patient's blood contained complement binding antibodies against the leptothrix strain in dilution down to 1:500. The manner of infection is unknown.

DISEASE OF THE UPPER RESPIRATORY TRACT

PROBLEMS CONNECTED WITH THE ETIOLOGY
AND PROPHYLAXIS

A R DOCHEZ MD

KATHERINE C MILLS

AND

YALE KNEELAND JR MD

NEW YORK

Influenza in its pandemic form is a dramatic calamity, happily seen only at long intervals of time. In recent years, however, minor winter outbreaks of epidemic disease of the respiratory tract, characterized by acute onset, prostration, fever and comparatively little involvement of the upper air passages, have more and more tended to be called influenza, although the identity of these disorders with pandemic influenza has been questioned. On the other hand, the common cold is always with us, it is regarded as a trivial disorder, and yet when one considers that it is the antecedent factor in sinusitis, bronchitis, bronchopneumonia and many cases of lobar pneumonia not to mention its more remote relationship to cardiovascular and renal disease, it appears in reality a very serious disorder indeed. It is also worthy of note that some relationship seems to exist between it and influenza at least the interpandemic type for it is a matter of common observation that an increased incidence of the one is usually found in conjunction with an outbreak of the other. It is not surprising, then, that much study has been devoted to this malady.

There is some relationship between the common cold and weather conditions, that weather was long thought to be of primary importance is indicated by the name of the disease itself. There is no question now, however, that the malady is primarily an infectious one and that the effect of weather is secondary. Convincing evidence of this lies in the well known observation that small colonies of individuals if wholly isolated from the outside world are completely free of colds as long as this isolation is maintained no matter to what extremes of cold and exposure they are subject.¹

From the Department of Medicine, Columbia University College of Physicians and Surgeons, and the Presbyterian Hospital.

Read before the Section on Pharmacology and Therapeutics at the Eighty-Fifth Annual Session of the American Medical Association, Milwaukee, June 16, 1933.

1. A recent clear-cut demonstration of this fact is to be found in the paper by H. H. Paul and H. L. Fiese (An Epidemiological and Bacteriological Study of the Common Cold in an Isolated Arctic Community [S. telegram] *Am. J. Hyg.* 17: 512 (1933)). The observers noted an almost total absence of disease of the upper respiratory tract until a few days after the arrival of the first ship in the spring. Then within a week, 5 per cent of the initial party were stricken. No significant change in the incidence of the upper respiratory tract could be demonstrated at this time.

Assuming then that colds are infectious, one may consider briefly successive steps in the search for the infecting agent.

By use of the plate method of bacteriologic study, it has been possible to isolate a large number of different micro-organisms from the upper respiratory tract, and as one or another of these has happened to be prominent in a given outbreak of colds, etiologic significance was naturally attributed to them. Thus, various streptococci, pneumococci, certain members of the gram-negative coccus group, staphylococci and *Haemophilus influenzae* were at different times thought to be the causative agents of the common cold. Further to complicate the bacteriology of the upper respiratory tract was the announcement in 1922 by Olitsky and his co-workers² of the discovery of a group of minute gram-negative organisms, present in nasal washings, which passed through a Berkefeld filter and grew only in the absence of oxygen. It can readily be seen that the finding of such a multiplicity of bacteria has served to make the problem more and more confused.

The problem of influenza on the other hand seemed at first more simple. In 1892, Pfeiffer³ announced the isolation of the bacillus now known as *Haemophilus influenzae*. During the pandemic of 1889 and for many years thereafter this organism was generally regarded as the cause of the disease. In 1918 however when the world was revisited by influenza, a vigorous controversy sprang up as to the exact role this organism played. Those who believed that *H. influenzae* was the etiologic agent pointed to its almost universal presence in cases of the disease studied in certain localities, whereas the opponents of this view emphasized the failure to isolate it in some regions, its presence in normal individuals, its low pathogenicity for animals, and the wide variety of strains recovered from simultaneous cases of the disease.

A systematic reevaluation of the relationship of Pfeiffer's bacillus to influenza has not been possible since that time, owing to the fact that no pandemic has occurred, and studies on the interpandemic form of the disease are open to criticism. On the other hand, valuable data have been accumulated dealing with the bacteriology of colds. In the past ten years several careful studies⁴ of groups of individuals not only

when suffering from colds but at regular intervals throughout the entire year, have shown that there is a "basal flora" of the upper respiratory tract composed not only of the organisms generally thought to be non-pathogenic but also for longer or shorter periods, of organisms that are known to be highly pathogenic, such as hemolytic streptococcus, pneumococcus, and *H. influenzae*. The presence of such organisms is by no means necessarily associated with symptoms of infection of the upper respiratory tract, they may not increase in number or incidence with the onset of an acute cold, and the only certain relationship that can be established between them and respiratory infection is their activity in the secondary inflammatory processes of the upper respiratory tract. Similar surveys dealing with the presence of the gram-negative filter-passing anaerobes in individuals throughout the year have shown that no causative role can be ascribed them in connection with the common cold. Consideration of these results has now led most investigators to believe that the cause of the common cold lies elsewhere than in the visible bacteria that can be cultivated from the upper respiratory tract.

On the other hand additional light on the mechanism of secondary infection has been thrown by recent investigations in infants.⁵ The upper respiratory tract of the infant is sterile at birth but during the first months of life a basal flora is acquired entirely comparable to that of adults and the first appearance of pathogenic organisms does not necessarily usher in disease. It has been observed that among institutional infants living in wards in which the opportunity for the dissemination of pathogenic agents is good, a very high incidence of respiratory disease occurs roughly between the ages of 8 and 14 months. In the early autumn, when the carrier rate for pathogenic bacteria is very low an outbreak of colds occurs without any alteration in the basal flora, these colds as a rule are mild and uncomplicated. The agent that produces these colds, however, seems capable of preparing the soil for the dissemination of bacteria since the carrier rate of pathogenic organisms begins to rise. In midwinter this carrier rate may reach a very high level, 80 per cent or more, and then a wave of respiratory disease occurs which is quite different in character from the autumn colds. This change is particularly noticeable in the highly susceptible group already described since in this group nearly every infant affected presents the picture of an acute illness either of the type of influenza or of that of an acute local inflammatory process. In an outbreak of respiratory disease of such a character there would seem to be two types of causative agents acting in cooperation, probably comprising an initiating agent which can give rise to a mild disturbance such as the common cold and in certain instances one or another pathogenic bacteria which are by it empowered to invade the host and give rise to more severe secondary manifestations.

Kiuse⁶ in 1914 was the first to suggest that colds may be due to a filtrable virus and he reported the experimental production of colds with bacteria-free filtrates. Foster⁷ in 1920 repeated these experiments

with similar results. Certain other observers failed in the attempt to confirm them. In the past five years a great deal of additional light has been shed on the importance of a filtrable virus in the etiology of colds. It has been demonstrated⁸ that chimpanzees are susceptible to colds and that these colds closely resemble those observed in human beings, when these animals are inoculated intranasally with bacteria-free filtrates of nasal washings obtained from early human cases of the common cold in about 40 per cent of instances they contract a typical common cold. This observation has been repeated many times and also extended to include human beings. In the case of the ape, in which one must rely wholly on objective changes to establish a diagnosis the incubation period of the experimental cold is ordinarily forty-eight hours. Human subjects however usually complain of the first symptoms within twelve to twenty-four hours from the time of inoculation. For the next forty-eight hours, as a rule manifestations of infection of the upper respiratory tract increase, improvement then rapidly takes place and symptoms have usually disappeared at the end of five days unless some complication develops. Most of these experimental colds have been mild and they resemble in every detail the disease as found in nature. In every study both on apes and on man a rigid quarantine has been established both before and after inoculation.

On chimpanzees, an observation of great interest was made following inoculation of bacteria-free filtrates from colds there was a springing into prominence of pathogenic bacteria previously inconspicuous in the noses and throats of the animals. In later studies¹⁰ a shift from the R to the S type of *H. influenzae* was demonstrated during the period of the cold and it was noted that in each instance when an S form appeared during the experimental cold, it was of the same type as the one recovered from that particular animal in previous colds. Only R forms (which have no type specificity) could be cultivated during intervening healthy periods. These results are suggestive experimental evidence that the etiologic agent of the common cold is able to activate pathogenic bacteria already present in the respiratory tract.

Many repetitions of these transmission experiments and many negative controls with material derived from normal individuals, are convincing evidence that there is present in the upper respiratory tract in cases of acute colds a filtrable virus that can give rise to a typical cold when inoculated into human volunteers or anthropoid apes. Further studies of the characteristics of this virus are now available. It survives anaerobically in the cold for at least thirteen days, it is inactivated at comparatively low temperatures by heat, and lastly,¹¹ it has been demonstrated to multiply in tissue culture medium of the type previously employed in the cultivation of vaccine virus. Positive experimental infections have been obtained with tissue cultures of the cold virus as many as fifty generations after the original seeding. These results, later confirmed by

Powell and Clowes,¹² indicate that the cold virus is similar to other typical filtrable viruses that have been carefully studied.

In regard to influenza, it seems logical to inquire whether or not a filtrable virus may be the cause. One is impressed with the extreme difficulty encountered in reproducing experimentally a picture that resembles influenza, even when presumably susceptible volunteers are brought into direct contact with acute cases of the disease, as was done by Rosenau.¹³ Various reports dealing with inoculation of cultures of *H. influenzae* leave the reader in doubt as to whether the disease produced was typical influenza. A series of experiments performed by Yamanouchi and others¹⁴ seems to point toward the presence of a filtrable virus in individuals suffering from pandemic influenza. They succeeded in producing what they described as the typical disease by inoculation of filtered blood and nasal washings into healthy volunteers. On the other hand, Costa Mandry and his co-workers¹⁵ in a recent sharp outbreak of influenza in Puerto Rico failed to communicate the disease experimentally to human volunteers. This study was made late in the course of the epidemic when changes in the susceptibility of the population to infection may have occurred. In 1931 Long and his associates¹⁶ reported the production in chimpanzees, inoculated with a filtrable agent derived from influenza of a syndrome characterized by prostration, fever and leukopenia. Additional evidence that a filtrable virus is the cause of influenza has recently been brought by Smith, Andrewes and Lairlaw¹⁷ who have produced an acute febrile infection of the respiratory tract of ferrets by intranasal inoculation of filtered nasopharyngeal washings derived from cases of influenza in human beings.

A filtrable agent has recently been cultivated in tissue medium from human cases of influenza in two separate outbreaks of the interpandemic form of the disease.¹⁸ In testing various generations of one of these culture strains on human volunteers, two types of response have been noted. One consisted of typical symptoms of a rather severe common cold; the other, of symptoms of irritation of the upper respiratory tract which were mild in character but, in addition, definite malaise, slight prostration and a little fever, the rise in temperature never exceeding 1 degree F. These experiments indicate that in the interpandemic form of influenza in instances of the disease that are clinically indistinguishable from pandemic influenza there is present a filtrable virus very similar in nature to that of the common cold.

The importance of the relationship of *H. influenzae* to human influenza has not as yet been satisfactorily determined. There has recently been investigation of a disease in animals, swine influenza, in which more than one etiologic agent is necessary in order to produce the

typical natural disease. The studies of Shope¹⁹ have shown that in this disease the active agent of infection is a filtrable virus. This virus, when present alone, produces a very mild disease. However, when there is added either in the natural or in the experimental disease the organism *H. influenzae*-suis this disease assumes a severe and fatal character. Experimental inoculation of pure cultures of *H. influenzae*-suis alone produces little or no manifestation of infection. The investigations thus far briefly reviewed indicate the complex nature of infections of the upper respiratory tract and the possible cooperative rôle played by filtrable viruses and visible bacteria. For many years, efforts have been made to mitigate the severity and cut down the number of these infections by employing vaccine composed of the visible pathogenic organisms of the respiratory tract. In view of the fact that many of these organisms are now believed to be secondary in their activity, the disappointment that has come from the use of such vaccine was to be expected. There are, however, many supporters of this method of prophylaxis, but most agree that the procedure is only partially successful. On the other hand many large studies carefully conducted with adequate controls have shown no real difference in incidence and severity of colds among the vaccinated as compared with the non-vaccinated groups. These studies²⁰ present strong evidence that at most mixed vaccines confer only the slightest protection against diseases of the upper respiratory tract. Since the initiating agent of the common cold is a filtrable virus, this result is not unexpected.

One might however hope to influence favorably the incidence and course of the secondary bacterial complications of the common cold by employing a vaccine comprised of the organisms concerned. We have made a study designed to throw light on this possibility. A simple antigenic mixture consisting of heat-killed cultures of pneumococci, *H. influenzae* and *Streptococcus hemolyticus*, organisms previously found to be important as secondary invaders, was selected for purposes of vaccination. This vaccine was given at weekly intervals over a long period of time, nine injections in the autumn followed by a similar number in February and March. Infants belonging to the age group highly susceptible to respiratory infection, previously mentioned, were chosen for immunization because in them the incidence of severe respiratory infection is very high. Because of the practical difficulties of the study incident to the careful bacteriologic observations made a small group comprising twenty infants was vaccinated. Unvaccinated infants of the same number and age, and living under exactly similar conditions served as a control group.²¹

A careful analysis of the clinical phenomena observed in the vaccinated group indicates the following outcome. There was no reduction in the number of simple colds or of respiratory infections associated with fever in the vaccinated as compared with the nonvaccinated

groups. There was, however, an apparent reduction in the severity of infections in the vaccinated infants as judged by the average duration of the febrile period. This was shorter by 40 per cent in the vaccinated as compared with the unvaccinated group. There were five instances of pneumonia among the nonvaccinated and only one among the vaccinated. This study indicates how incomplete the protection is which results from such a vigorous course of vaccination against the organisms presumably concerned. The technic of carrying out such immunization is time consuming and burdensome and, in view of the relatively slight protection obtained, does not seem promising for general use.

Certain other measures have been extensively employed in the attempt to prevent infection of the upper respiratory tract. Among these has been the addition of high concentrations of certain vitamins to the diet. Early investigators, who noted that the chronic respiratory disease of rats on a diet deficient in vitamin A could readily be cured by feeding vitamin A, hoped that the addition of large quantities of this vitamin to the diet might enhance human resistance to respiratory disease. Consequently, large amounts of this and other vitamins have been fed to groups of individuals and the effect on the incidence and character of respiratory infection has been observed. The careful studies of Barenberg and others²² are convincing evidence that children given large doses of vitamins A and D fare no better in regard to the occurrence of respiratory disease than do those on an ordinary diet.

In addition to its antirachitic properties, ultraviolet radiation has been proposed as an aid to general health, and this agent has also been tried as a prophylactic measure against colds in adults. The well controlled studies on this subject in the Johns Hopkins group, however, seem to indicate that regular exposure to ultraviolet rays does not diminish the incidence of colds in the light-treated group. These investigators²³ have also analyzed the importance of abnormalities of the upper air passages, hygienic sleeping conditions, clothing, exercise, habits and the like in susceptibility or resistance to respiratory infection. They have not found that any of these factors play an important role in determining the incidence of infections of the upper respiratory tract.

A consideration of the results obtained up to the present from efforts to prevent or control infection of the upper respiratory tract leads one to ask whether any clues exist that may be followed with any hope of success in solving the problem of colds and influenza. The most promising method of attack would seem to derive from the newer conceptions of these diseases, which have been developed in recent years. The knowledge that they are primarily infectious due to agents belonging to the group of filtrable viruses and that in some instances the etiology may be complicated by the presence of one or more of the well known pathogenic bacteria should so clarify the understanding of them that henceforward more rational methods of control may be undertaken.

THE TREATMENT OF SCARLET FEVER WITH ANTITOXIN

LUKE W. HUNT, MD

CHICAGO

The most important factors in the management of scarlet fever are the early diagnosis of the disease and the administration of an adequate amount of scarlet fever antitoxin. If this is done, a favorable effect will be noted on the severity of the febrile stage of the disease, on the course and duration of the fever, on the intensity and duration of the skin lesions, and on the occurrence of complications. These statements are supported by numerous reports that have appeared in the literature during the last few years, and by a study of 2,303 cases of scarlet fever admitted to the Durand Hospital during the years 1924 to 1931 inclusive, in 882 of which scarlet fever antitoxin was administered. This study deals with the last group. The antitoxin used was commercial concentrated and refined serum, standardized by means of skin tests in susceptible persons. One therapeutic dose (sufficient antitoxin to neutralize 300,000 skin test doses of toxin) was given intramuscularly in most cases, although in some of the severe cases two, three, four or more therapeutic doses were given. The dosage and accurate standardization of the antitoxin are important factors in evaluation of the effect of the antitoxin, and the results obtained by various workers can be compared only when this has been recorded and taken into consideration.

It is realized that scarlet fever is a disease subject to wide variation in severity from year to year, and even within the same season, and with this fact in mind the results were tabulated for each year, but the comparative results obtained in the cases in which antitoxin was administered and in those in which antitoxin was not administered did not vary to any extent throughout the entire period. Furthermore, to make the study of the two series as comparable as circumstances would permit, the cases were divided into mild, moderately severe and severe, according to the symptoms. The mild cases are those presenting little fever, and mild and transient eruptions, moderately severe cases are those in which the temperature was in practically all instances 102 F. by mouth and in which there was a moderate degree of toxemia, the cases described as severe were characterized by high fever, extensive eruption, stupor, delirium or severe septic complications. Of the 882 cases in which antitoxin was administered, 275 were classified as mild, 487 as moderately severe and 120 as severe cases, while in the group in which antitoxin was not administered 573 were mild cases, 743 were moderately severe and 105 were severe cases. The general treatment aside from the use of antitoxin was the same in the two series. At first antitoxin was given only to the sickest patients; later it was given all acutely sick patients. It is thought that the cases in which antitoxin was not administered during the period of eight years furnish quite an accurate control to the ones in which antitoxin was administered. Any disparity should operate against the results in the antitoxin group.

In attempting to evaluate the results obtained from the use of the antitoxin attention has been concentrated

Aided by a grant from the Fenger Memorial Fund From the John McCormick Institute for Infectious Diseases Read before the Section on Pharmacology and Therapeutics at the Eighty-Fourth Annual Session of the American Medical Association Milwaukee June 16, 1933

principally on its value in the prevention of complications and to a lesser extent on its effect on the general clinical course of the disease. The favorable effect of the antitoxin on the clinical course of the disease has been observed by practically all workers who have used the antitoxin extensively.

EFFECT OF SCARLET FEVER ANTITOXIN ON THE CLINICAL COURSE OF THE DISEASE

In early cases the rash is the most convenient indicator of the action of the antitoxin. If enough antitoxin has been given, the typical punctate rash fades within twelve to twenty-four hours and may be absent with only a subcuticular flush persisting. If the rash has been present for three or four days, the effect of the antitoxin on the rash is not so striking but it has a tendency to run a course somewhat similar to the rash in cases in which antitoxin has not been administered. Corroborative evidence that the skin lesions are milder is shown by the fact that the degree of desquamation is markedly less in patients receiving antitoxin, being usually slight and lasting sometimes for only a few days. With the disappearance of the rash there is a marked improvement in the general condition of the patient, especially noticeable in toxic cases. Another

effect of the antitoxin is the unmasking of such complications as are already present. The removal of the toxic element of the disease makes the recognition and proper treatment of early complications more certain. The manner in which scarlet fever antitoxin influences the fever during the acute stage of the disease is an important index of the general effect on

FIG. 1.—Composite temperature charts of uncomplicated cases: solid light line, twenty moderately severe cases treated without antitoxin; broken light line, twenty moderately severe cases treated with antitoxin; solid heavy line, twenty severe cases treated without antitoxin; broken heavy line, twenty severe cases treated with antitoxin.

the clinical course. This effect is shown in the accompanying chart. Often there is a slight rise in temperature after the injection of serum followed within a few hours with a marked decline in practically all cases in which sufficient antitoxin has been administered early in the disease. Frequently there is a decline from 104 or 105 F within twenty-four hours. However, if the antitoxin has been given relatively late in the disease the fever is practically always favorably modified but usually not to the same extent as in those cases in which antitoxin is administered earlier.

COMPLICATIONS

Aside from the toxic and septic cases the febrile period of scarlet fever is not attended with particular danger. Most deaths result from complications which likewise constitute the major medical problems. Complications develop in a fairly high percentage and therefore are more to be feared than the chances of death.

The frequency of the more important complications in the series in which antitoxin was administered and in the series in which antitoxin was not administered is presented in tables 1, 2, 3 and 4. From a study of these results three striking facts are disclosed: 1. A

large number of serious complications occurred in the mild cases in which antitoxin was not administered. 2. A large number of severe cases were free from complications in the series in which antitoxin was administered, in contrast to the large number of severe cases that showed complications in the series in which

TABLE 1.—Complications in 848 Mild Cases of Scarlet Fever, With and Without Antitoxin

Complications	Percentage of Complications in 270 Cases According to Day of Attack on Which Antitoxin Was Given					Total Percentage	Percentage of Complications in 777 Cases Without Antitoxin

antitoxin was not administered. 3. A small number of complications occurred when the antitoxin was given during the first two or three days of the disease.

It has been said that mild scarlet fever was of little value in evaluating the effect of antitoxin, but this is not the case, since practically every physician who has treated many cases of scarlet fever has frequently observed the serious complications that may develop from mild cases. In this series, in the group of mild cases in which antitoxin was not administered there were eighteen cases of suppurative otitis media, in two of which mastoiditis developed and operation was performed, seven cases of acute hemorrhagic nephritis, cervical abscesses developed in two and there was one

TABLE 2.—Complications in 1230 Moderately Severe Cases of Scarlet Fever With and Without Antitoxin

Complications	Percentage of Complications in 457 Cases According to Day of Attack on Which Antitoxin Was Given					Total Percentage	Percentage of Complications in 771 Cases Without Antitoxin

case of bronchopneumonia and one of streptococcal meningitis. Of the 120 severe cases in which antitoxin was administered 51 were without complications, while in 105 severe cases in which antitoxin was not administered only 5 were without complications. Most of the serious complications in the group in which antitoxin was administered occurred in those in which antitoxin was given on the fourth day of the disease.

or later. In some of these cases the complication had already occurred or was in the incipient stage when the antitoxin was given. No pronounced effect was observed on the course of complications that had appeared before antitoxin was given. Definite differences appear in the frequency of complications in the two series.

TABLE 3—Complications in 225 Severe Cases of Scarlet Fever, With and Without Antitoxin

Complications	Percentage of Complications in 120 Cases According to Day of Attack on Which Antitoxin Was Given						Percentage of Complications in 101 Cases Without Antitoxin
	First Day 1st Cases	Second Day 30 Cases	Third Day 24 Cases	Fourth Day 16 Cases	Later Than Fourth Day 35 Cases	Total Per centage

Deaths	0	6.6	0	12	25.5	11.6	21.9
Total percentage	26.6	26.6	62.5	87	57	91	92

Suppurative otitis media occurred in 18 mild cases, in 112 moderately severe cases and in 35 severe cases in the series in which antitoxin was not administered, while there were 3 cases of suppurative otitis media in the mild cases, 10 in the moderately severe cases and 23 in the severe cases in which antitoxin was administered. In 12 of the 23 severe cases in which the complication developed, the antitoxin was given on the fifth day after the onset of the disease or later. Of the total number in which antitoxin was not adminis-

tered the series in which antitoxin was administered. There were also fewer cases of mild nephritis, cases that showed albumin and casts for several days, in the series in which antitoxin was administered. Cases of transient albuminuria that appeared at the height of the febrile period are not included in this group.

Multiple arthritis occurred principally in the moderately severe and in the severe cases. There was a marked variation in the tendency to arthritis at different times during the various years. It was most frequent in the second and third decades of life and was especially apt to occur in those patients who had had rheumatism previously. The frequency of this complication is less in the series that received antitoxin but in some instances the condition may have been diagnosed as part of a serum reaction when in reality it was true scarlatinal arthritis.

A mild to moderate degree of cervical lymphadenitis is present in practically every case of scarlet fever and is considered a part of the disease. Severe cervical adenitis appeared in 1 mild case, in 2 moderately severe cases and in 3 severe cases in which antitoxin was administered while there were 3 in the mild cases, 7 in the moderately severe and 9 in the severe cases in which antitoxin was not administered. Among this group, cervical abscesses developed in 10 cases in which antitoxin was administered and in 19 cases in which antitoxin was not administered.

Purulent sinusitis was less frequent in the series in which antitoxin was administered except in the severe cases in which there was a slight increase. Sinusitis is commonly present at the onset of the disease and before the development of the rash, so that one would not expect its incidence to be influenced by antitoxin. Six cases of orbital cellulitis secondary to an ethmoiditis occurred in the series in which antitoxin was not administered and in 2 cases in which antitoxin was administered.

Eight cases of myocarditis, four of endocarditis and one of pericarditis were recognized in the series in which antitoxin was not administered while four cases of myocarditis and two of endocarditis were recognized in the series in which antitoxin was administered. In two of the latter antitoxin was given on the fourth day or later of the disease. Two cases of myocarditis and one of endocarditis in the series in which antitoxin was not administered resulted in death, while two cases of myocarditis in the serum-treated group proved fatal.

Pleurisy with effusion occurred in five cases in which antitoxin was not administered and in two cases in which antitoxin was administered, one on the eighth day of the disease and one on the second day of the disease.

Acute appendicitis occurred in two cases in which antitoxin was not administered. One of these patients was operated on.

Osteomyelitis of the femur occurred in one case in which antitoxin was given on the third day.

There were five cases of recurrent scarlet fever in the series. In two of these antitoxin was given on the second day of the disease, and in the others, antitoxin was not administered.

There was one death (of streptococcal meningitis) in the mild cases, one in the moderately severe and twenty-three in the severe cases in which antitoxin was not administered while there were no deaths in the mild and moderately severe cases and fourteen deaths in the severe cases in which antitoxin was administered. In two of the fatal cases in the antitoxin-treated series

tered mastoiditis developed in 34 and operation was performed, while there were 8 such cases in the series in which antitoxin was administered. In 5 of the latter, antitoxin was given on the fourth day of the disease or later.

Acute hemorrhagic nephritis occurred in 7 mild cases, in 10 moderately severe cases and in 13 severe cases in the series in which antitoxin was not administered while this complication developed in none of the mild cases, 2 moderately severe cases and 4 severe cases in

antitoxin was given on the fourth day, and in ten on the fifth day or later of the disease. Four of these patients died within eighteen hours after admission. In the series in which antitoxin was administered, only two deaths occurred in patients that had received antitoxin before the third day. One of these died of streptococcal meningitis twelve hours after admission.

In a recent study of serum reactions in 876 cases of scarlet fever, the cases recorded in this series in which scarlet fever antitoxin had been administered, it was found that reactions occurred in 22.7 per cent, or in 20.8 per cent if cases presenting a history of previous administration of serum were excluded. The same study showed serum reactions in 28.1 per cent of 2,859 patients who had received diphtheria antitoxin. It was also stated that the frequency of these reactions depended on the susceptibility of the individual, the previous administration of serum, the toxicity of the serum, the age of the serum and to the greatest extent on the amount of serum injected. One of the most important factors in determining the frequency of serum reactions in scarlet fever is the previous administration of serum, as many of these patients have been immunized with toxin and antitoxin or have had

obtained when the antitoxin is given early in the course of the disease and in sufficient dosage.

5 Serious complications often develop from mild cases of scarlet fever treated without antitoxin.

6 Serum reactions occurred in 22.7 per cent of the patients of the series or in 20.8 per cent if those with a history of previous administration of serum are excluded. They were not more severe and were less frequent than after the use of diphtheria antitoxin.

AN ANTISERUM FOR THE TREATMENT OF TULAREMIA

LEE FOSHAY, M.D.

CINCINNATI

The antiserum used in these clinical trials was made by inoculating goats subcutaneously with formaldehyde-killed suspensions of *Pasteurella tularensis*. One batch of serum represented mainly avirulent strains. For all others virulent strains were used. None of the serum was concentrated or refined. It was cleared by centrifugation or filtration and different samples were treated or used in different ways. Some were preserved with phenol, some were preserved with merthiolate, and some were used without a preservative. Some were used when fresh and others were stored for from three months to one year before using. Dosage has been varied both in amount and in number of injections to determine if possible the general requirements for cases of average severity. Serum has been administered subcutaneously, intramuscularly and, most frequently, intravenously.

The diagnosis has been confirmed in each case by agglutination or intradermal tests, frequently by both procedures. The third year's experience with the intradermal reaction provoked by injection of the standardized detoxified suspension confirms the results of previous studies.¹ The response is absolutely specific and certain if the test is made properly. The reaction will betray the presence of tularemic infection from the second day to the fifteenth month of disease. It is especially useful during the first twelve days, when agglutination tests are usually negative. Positive reactions were obtained with negative agglutination tests in seven early cases in this series.

Sixty-nine patients received the serum. Thirty-one were treated and studied by me and the remainder were treated at other hospitals or by their personal physicians. No patient was treated during the first six days of illness. Five were treated on the seventh day and eight more before the end of the tenth day. The majority were treated during the first five weeks of illness, the average time of receiving serum being the twenty-first day of disease. Four deaths occurred. In one case the disease was complicated by diffuse arteriolar sclerosis of long standing with nephritic and cardiac failure. In the other three there were extensive tularemic infiltrations of the thoracic and abdominal viscera before serum was given.

Following adequate serum therapy there is a rapid fall in temperature, a marked diminution in the sizes

TABLE 5—Frequency of Serum Reactions in Scarlet Fever Patients Receiving Different Quantities of Scarlet Fever Antitoxin

Amount of Therapeutic Serum Doses	Cases Showing Reaction			Total Cases	Percentage of Cases Showing Reaction	Percentage of Cases Showing Reaction Excluding Those with History of Previous Administration of Serum
	No History of Previous Administration of Serum	History of Previous Administration of Serum	Cases Observed Ten Days or More Without Reaction			
10-15	1	168	27	635	22.3	20.8
20-30	2	7	2	34	20.6	
30-54	3		5	5	0	
50-72	4		4	4	0	
70-93	5	1	4	5	20.0	
		176	22	618	22.7	

diphtheria or tetanus antitoxin. With the general use of toxoid for immunization against diphtheria and new methods of concentrating and refining the serum, it is to be expected that the frequency of serum reactions after the use of any antitoxin will be less than at present. In this series the reactions were not more severe than after the use of diphtheria antitoxin. The frequency of serum reactions in this series is recorded in table 5.

CONCLUSIONS

Results in 2,303 cases of scarlet fever of different degrees of severity, in 882 of which scarlet fever antitoxin was administered indicate that:

1 Scarlet fever antitoxin exerts a favorable influence on the clinical course of the disease. This is evidenced by a lessened severity of the febrile stage of the disease, on the course and duration of the fever and on the extent and duration of the skin lesions.

2 Complications are less frequent in patients treated with an adequate dosage of scarlet fever antitoxin.

3 Almost all the complications that occurred in the series in which antitoxin was administered appeared in patients who received the antitoxin relatively late in the disease.

4 As in diphtheria, the best results in the treatment of scarlet fever with antitoxin on the clinical course of the disease and the prevention of complications are

1. Foshay, Lee. Tularemia: Accurate and Earlier Diagnosis by Means of the Intradermal Reaction. *J. Infect. Dis.* 51: 266-271 (Sept. Oct.) 1933.

of the enlarged lymph nodes and disappearance of pain at the sites of glandular enlargements. If a painful primary lesion is present, the pain soon disappears and an acceleration in the healing process is noted. Erythematous lesions usually disappear within a week. Relief from severe headache is often the first noted favorable change occurring usually the day after the first serum injection. Arthralgias, myalgias and general malaise are usually greatly lessened during the first three days and may disappear entirely, but sometimes they recur intermittently for brief periods until complete convalescence is established.

Coincident with these changes there is a fall in the leukocyte count and a complete disappearance or very marked diminution in the reaction to subsequent intradermal tests. This desensitizing action of the serum is very striking and seems to be closely associated with its curative action. A completely negative skin test three or four days after administration of the serum almost always indicates a prompt and uneventful convalescence whereas positive reactions at this time have almost invariably preceded a recurrent glandular enlargement later in convalescence or a prolonged return of myalgias and malaise occasionally with recurrent brief periods of low grade fever. Hence the skin test may be used as a fairly reliable index of the adequacy of serum treatment and as a prognostic aid in estimating the length of convalescence and the likelihood of occurrence of sequelae.

Without taking sides in the controversy concerning the harmful versus the beneficial role played by the allergic or hypersensitive state in infections, I would like to emphasize that the rate of recovery and the degree of completeness of recovery from tularemia induced by specific therapy vary directly as the rate

the majority have fallen to about 1:40, and often with a previously absent prozone inhibition in dilution 1:10. One patient became infected during the third month of pregnancy. She responded favorably to serum treatment and was well two months after the onset of infection. She came to term without difficulties and delivered a normal baby. Agglutination tests were made with serum from both maternal and fetal bloods. Each was positive in all dilutions through 1:160, showing that these agglutinins can pass the placenta.

Chart 2—Effect of inadequate treatment in two patients given single small doses of potent serums

A very important therapeutic result is the great shortening of the period of disability. Five men were able to return to arduous rabbit hunting within ten days from the injection of serum. Eleven patients treated in the laboratory were maintained as ambulatory cases. Seven of these did not have to abandon their customary work for as much as one week and the remainder were able to resume their usual work before the end of the second week. This is in great contrast to the general experience with untreated cases, although there is not sufficient reliable information on this point to make an accurate comparison.

One patient who had received one small injection of goat serum showed the usual temporary improvement in regard to temperature and sizes of involved lymph glands. On the twenty-third day after the injection of serum he was having malaise as severely as before and had four lymph glands each at least 1 cm. in diameter in one axilla. Extreme sensitivity to goat serum made it unwise to try it again. With the hope of shortening the disease and preventing glandular suppuration, he was given by vein 18 cc. of my own serum. At the time of injection he had an indurated, painful, 9 by 7 cm. inflammatory reaction from a positive skin test on his forearm. Thirty hours after the injection of my serum he was free from malaise, his lymph glands were impalpable and the reaction to the skin test had been entirely effaced. This seems to me to be strong evidence in support of my belief that vaccination of laboratory workers as I have practiced it, is an efficient prophylactic measure.²

The goat antiserum is not bacteriostatic or bactericidal. On the contrary, its effect on living bacteria, as judged by animal inoculations, seems to be an exaltation of virulence. Nor is it protective for mice, rats, guinea-pigs or rabbits, even in amounts very large in relation to the weights of these animals as compared with effective human doses. Its beneficial action in man seems to be due to the reduction of inflammatory

Chart 1—Effect of antiserum on temperature and enlarged axillary glands in two patients adequately treated with a single intravenous injection

and degree of reduction of the specific hypersensitivity. This has been observed in patients treated by vaccines as well as in those treated by antiserum.

In one patient with the typhoidal type of disease the serum caused a rapid rise in the phagocytic index from 18 per cent to 100 per cent, although it did not prevent his death. The effects of serum therapy on agglutinin titers have been very irregular. Some titers have been greatly increased a few have disappeared entirely and

edema and stimulation of phagocytosis, both of which seem to be dependent in some way on its desensitizing property

Chart 1 shows the effect of the antiserum on the temperature and the enlarged lymph glands in two patients who were adequately treated by a single intravenous injection. Experience has shown that single doses of from 10 to 15 cc are not sufficient for the case of average severity. Out of thirty-five such patients treated with one injection, only twelve made rapid recoveries. In case 34, the irregular temperature that follows four successive afebrile days is due to serum sickness, the longest and most severe that has occurred. The serum used in this case was made almost entirely from avirulent strains. Out of ten patients treated with this batch of serum, only two made good recoveries. These two received 18 and 23 cc of it, respectively. In doses from 10 to 15 cc its potency seemed to be low. Case 43 shows a fairly good therapeutic response to a small single dose of serum made from virulent strains only.

Chart 2 shows the effect of inadequate therapy in two patients treated by single small doses of potent serums. The delayed fall in temperature and the secondary enlargement of glands after an initial reduction are characteristic. Glandular suppuration occurred in each case, on January 14 in case 31. It seems probable now that at least half of the patients received too little serum. The very mild short period of serum sickness in case 41 is representative of 90 per cent of such disturbances.

Chart 3 shows the effect of two doses of potent serum in a case of unusual severity. The patient had diffuse bronchitis and bilateral pleurisy and was profoundly intoxicated. Large multiple painful ulcers were present on each hand. The therapeutic result was extremely good. The serum sickness was mild and

Chart 3—Effect of two doses of potent serum in a case of unusual severity

caused no constitutional disturbance as is usually the case. This patient was doing all the work in a large house and managing a large family of children with scarcely more than normal fatigue six weeks after the onset of illness.

SUMMARY

The antitularense goat serum has been shown to have a favorable therapeutic effect on tularemia in man. Although approximately half of the patients are now believed to have been inadequately treated because of the testing of the variables mentioned in the first paragraph the mean duration of disease of the entire group has been reduced to almost one-half that of the control series. The duration of adenopathy and the period of disability have been appreciably and significantly shortened. The mean febrile period has not been shortened. As many of the patients were treated late in the course

of disease, and as febrile days due to serum sickness were included in the analysis, this result is not surprising. The incidence of serum sickness was somewhat high for the small amounts of serum that were used, but only four occurrences could be called severe and none were serious. The great majority were so short and so mild that they were of little consequence. The incidence of suppurative adenitis was higher than anticipated. I believe this was because insufficient serum was given to such a large proportion of the patients.

Recommendation for dosage for future patients with infections of average severity would be two intravenous injections of 15 cc each, on successive days, of an antiserum made from virulent strains of the organism. When the lymph glands are already larger than 5 cm in diameter, three such doses would be better if glandular suppuration is to be prevented. Patients with the typhoidal type should also be given serum in much larger amounts.

Most important of all is the matter of early diagnosis. If diagnoses can be made and confirmed before the tenth day of disease and if patients can be treated, I believe that many deaths can be prevented, also that most of the prolonged distress caused by tularemia can be greatly shortened. The general use of the intradermal test in conjunction with the antiserum could make this desirable situation possible.

IMMUNIZATION WITH BACILLUS PERTUSSIS VACCINE

LOUIS W. SAUER, M.D.

EVANSTON, ILL.

That untreated whooping cough may run a mild course has long been known. Before the days of pertussis vaccine Neurath in the first edition of Pfandl and Schlossmann's "Handbuch," says "bed-rest in a fresh, warm, dust-free atmosphere without drafts, not infrequently aborts the disease." And Pospischill, in his book "Pertussis," written after he had seen over 25,000 cases, says "Most whooping cough patients need no physician but those who do, need him badly." The outstanding pertussis vaccine study is that of the Danish physicians who injected in the Faroe Islands, 2,094 patients and 364 children as a prophylactic measure. In the Cutter Lecture, Madsen¹ says "Vaccination has no effect once the disease has broken out."

It should be used to the widest possible extent as soon as an epidemic threatens. Vaccination is most effective if completed a week before the disease breaks out.

The effect is greatest in patients showing a strong reaction at the point of injection. No absolutely sure prophylactic effect has been obtained but the infection is lighter.

Three hundred and sixty-four children were injected one to three months before being exposed to contagion, in spite of this they all without exception caught whooping cough.

The epidemic on a whole was very light. Their conclusions differ little from my own experience with the various commercial vaccines used between 1915 and 1925. Because the advocates of pertussis vaccine failed to bring sufficiently convincing and adequately controlled evidence during

the twenty years that passed after Nicolle and Connor first used *Bacillus pertussis* vaccine, it was removed from New and Nonofficial Remedies in 1931.

In diagnostic cough-plate work that my associates and I have carried on since 1925, Miss Hambrecht noted that hemolysis was usually more pronounced in freshly isolated strains than in cultures long under cultivation. Bordet and Sleswyck² had found in 1910 that recently isolated strains differ serologically from old stock cultures grown without blood. Since 1925

TABLE 1—*Prophylaxis and Immunization Compared*

	Prophylaxis (Danish Study 1923)	Immunization (Livinston Study 1923-1924)
Number of susceptibles	364	791

Result	All contracted pertussis	None contracted pertussis

we have made B. pertussis vaccine according to the Danish Statens Serum Institut specifications, except for the following details. From five to seven recently isolated, strongly hemolytic strains have been selected each time the vaccine has been made, because hemolysis was considered a criterion of virulence. Since the only known habitat of the Bordet-Gengou bacillus is man (and it is naturally pathogenic only for him) the bacillus is grown on medium made with fresh, defibrinated human blood. To minimize the culture medium content, the forty-eight hour growth is scraped off and mixed with 0.5 per cent phenolized physiologic solution of sodium chloride. To insure purity a stained smear of each surface growth is examined before it is harvested. After a week in the refrigerator (during which time it is shaken daily), the concentrated suspension is cultured for sterility on three successive days. After dilution with 0.5 per cent phenolized physiologic solution of sodium chloride so that 1 cc. contains about 10 billion bacilli, it is tubed, sealed and refrigerated until shortly before it is used. Vaccine so prepared, preserved and refrigerated should possess marked antigenic value.

Between 1925 and 1928, 100 whooping cough patients and exposed susceptible children (in families with pertussis) were given three injections at intervals of four days (0.5, 0.7 and 1 cc.)—a total of 22 billion bacilli, as directed by Madsen. The only death was in an infant who contracted pertussis bronchopneumonia during the second week after the injections. Compared with 100 unvaccinated patients seen during that time (controls), no mitigation of symptoms could be attributed to the vaccine. The number of mild and severe cases in the two groups was about equal.

Since May, 1928, the vaccine has been used as an immunizing agent. Detailed evidence of active immunization, presented in a preliminary report³ has been augmented by sufficient new data to justify the present five year summary. A total of 394 selected young non-immune children have been injected with from 7 to 8 cc.

of the vaccine several months before any were exposed. In most families an older, susceptible child served as control. Since 1931, the total of from 70 to 80 billion bacilli is divided as follows. One cubic centimeter is injected into the deltoid region of each arm, a week later 1.5 cc. is injected into the biceps region of each arm, a week later, 1.5 cc. is injected into the triceps region of each arm. Last year, to determine whether the entire amount could be given in one injection, 0.7 cc. of a vaccine containing 50 billion bacilli per cubic centimeter was injected in each arm in a small series of young children. Because about 20 per cent of the injections were followed by a small, sterile local abscess the customary routine was resumed.

The parents are forewarned of a transient rise in temperature, the temporary local reactions (redness, induration and tenderness) and the subcutaneous nodules which may persist for a few weeks at the site of each injection. Their eager cooperation, although immunity is not assured, bears testimony to what extent this disease is dreaded by the parents of young children. Only two among those solicited in the course of five years did not grant permission.

The local and systemic reactions are due to the vaccine (dead bacilli and endotoxin), not to the phenol or to medium proteins. The human blood in the medium eliminates reactions due to alien blood proteins. Allergic reactions, sensitization to foreign protein or susceptibility to the Arthus phenomenon need not be feared regardless of the amount of vaccine injected or the time interval between injections. All but 3 of more than 2,000 injections were given on the scheduled day. No infection of the skin has occurred. If a very severe reaction follows an injection the next injection may be postponed a few days or only 1 cc. may be given (bilaterally) at subsequent injections and an extra one given a week after the third injection. During 1933 more than a hundred "Cradle" infants less than 3 months of age have been given 1 cc. (bilaterally) for three successive weeks—a total of 6 cc. in fourteen days. Reactions were surprisingly mild. Although it has not yet

TABLE 2—*Immunization with Bacillus Pertussis Vaccine*
(Total 70-80 Billion Bacilli)

Series	Number of Susceptibles Injected	Average Age	Number of Household Exposures	Number of Accidental Exposures	Contracted Pertussis
1928-1929	100	28 mos.	9	87	0
1930	94	18 mos.	7	44	0
1931	83	14 mos.	8	27	0
1932	103	11 mos.	5	4	0
Five year total	394	18 mos.	29	162	0
1933	85	8 mos.	0	0	0

been determined whether infants so young will develop an active immunity from a total of 60 billion bacilli, the managing director of the Cradle has requested that the injections be continued as a routine procedure.

The accompanying tables are submitted as proof that active immunity was conferred by the vaccine. In the course of five years the thirty-one control children in twenty-four of the families contracted typical whooping cough. Positive cough plates, lymphocytosis and the nature of the cough verified the diagnosis. Twenty-nine of the injected children were thus exposed to their coughing brothers or sisters. The infected were not separated from the injected, but they were urged to play and eat together throughout the quarantine period. In two families of three children each an un.injected

² Bordet J. and Sleswyck. Serodiagnostic et variabilité des microbes suivant le milieu de culture. Ann. Inst. Pasteur 24: 476, 1910.
³ Sauer, Louis. Whooping Cough. A Study in Immunization. J. A. M. A. 100: 239 (Jan. 28) 1933.

infant contracted the disease from the control child, but the child injected three years previously escaped. In one family, twin girls (controls) contracted pertussis simultaneously during an epidemic in school, their younger sister, injected four years previously at the age of 9 months, escaped. In twelve recent cases of typical whooping cough in the controls, the injected child was tête-à-tête with the coughing control at the time the (positive) cough plate was exposed. The children kissed each other at the completion of the cough plate exposure, but the injected child failed to contract the disease. The injected children were exposed daily throughout the incubation, catarrhal and paroxysmal stages, but none contracted whooping cough. Not one of the 162 injected children accidentally exposed during the five years has had a cough that in any way resembled pertussis.

Because the disease is relatively benign except for the first two years of life,⁴ and as four months should elapse for immunization to occur, injections should be started early, preferably during the second half year of life.

COMMENT

The comparative complement fixation tests of Huenekens⁵ made it seem doubtful whether vaccine several months old would be effective. The more recent work of Mishulow, Oldenbusch and Scholl,⁶ however, shows that properly prepared and preserved pertussis vaccine, stored at from 8 to 10 C, will keep its antigenic potency for several years. Leslie and Gardner⁷ have concluded that the pertussis bacillus is a uniform species without fixed types and that all strains fall into four agglutinative groups or phases. They say that "for prophylactic vaccination in the human subject phase I vaccines made from recently isolated strains are more promising than those made from old cultures." Sauer and Hambrecht⁸ in the isolation of B pertussis bacteriophage, found that freshly isolated strains differ from old laboratory cultures in morphology and colony formation.

Without a reliable immunization test (skin test), actual exposure remains the ultimate test of immunity. The data at hand lead one to believe that pertussis vaccine is not a curative agent but that, like B typhosus vaccine, B diphtheria toxoid and S scarlatinae toxin, it will actively immunize susceptible persons. In the immunization process three factors seem to play a role: the potency (recently isolated strains grown on medium made with human blood) the dosage (twenty times the Huenekens three times the Madsen dose), and the time interval (at least several months) between injection and exposure. Until the relative importance of each factor has been determined or until potency tests or standards have been established, all details of technique should be adhered to. It is urgent that the maximum potency of the material be maintained.

In anticipation of the trials to which the vaccine might be subjected when prepared and distributed com-

mercially,⁹ the added question of age limit or deterioration assumes importance. To retard deterioration the vaccine should be preserved in nonsoluble glass vials with nonsoluble rubber stoppers and should be refrigerated until shortly before it is used by the physician. The data so far available seem to indicate that, if the vaccine is prepared, preserved and refrigerated as outlined, it probably will retain its antigenic power for twelve months (or more) after it is made. These precautions should facilitate the production and distribution of potent material.

SUMMARY

Bacillus pertussis vaccine (1 cc = 10 billion bacilli), made from recently isolated, strongly hemolytic strains, grown on Bordet medium made with freshly defibrinated human blood, has been injected as an immunizing agent in 394 selected young nonimmune subjects. The total of 7 to 8 cc (70 to 80 billion bacilli) is divided into three weekly (bilateral) injections of 1, 1.5 and 1.5 cc, respectively. In the course of five years the thirty-one control children in twenty-four of the families contracted unquestionable whooping cough. Twenty-nine of the injected children were exposed throughout the incubation, catarrhal and paroxysmal stages but none contracted the disease. Not one of 162 injected children accidentally exposed has had a cough that in any way resembled pertussis. Active immunity is completed in four months and lasts for years. Infants withstand the injections remarkably well. The best age for immunization is the second half year of life.

CONCLUSION

From 7 to 8 cc of a special B pertussis vaccine (containing 10 billion bacilli per cubic centimeter) protects the nonimmune child if the injections are completed at least four months before exposure occurs.

636 Church Street

ABSTRACT OF DISCUSSION

ON PAPERS OF DR. DOCHETZ, MISS MILLS AND
DR. KNEELAND, DR. HUNT, DR. FOSHAY
AND DR. SAUER

DR. WILLIAM H. PARK, New York. At the Willard Parker Hospital at the beginning of the antitoxin treatment of scarlet fever, we alternated cases and found that those presenting a high temperature and especially those definitely toxic, were greatly benefited by the serum. We found that patients with a temperature of less than 102 showed but a slight benefit and we thought that was more than compensated for by the serum sickness which frequently developed. We therefore made it a rule to give the serum only to patients with a temperature of 102 or over. We found that the intravenous injections gave much more prompt results in toxic cases than intramuscular injections. More work ought to be done on the antibacterial part of the serum because when the disease has advanced to the septic stage the antitoxic serum has no effect. Apparently an antibacterial serum has a definitely curative effect in some of these cases. I certainly endorse Dr. MacVail's statement that physicians should try to know the type of microorganism concerned before they use the specific serum or the bacteriophage. I was greatly interested in Dr. Sauer's report. We have tried every method of immunization against whooping cough that has been suggested. The results on the whole were very disappointing. We have never used the amounts which Dr. Sauer is using. I think that possibly Dr. Kneeland has gone too far in denying that ordinary bacteria start a common cold. In the big epidemic of 1918 three of my technicians were accidentally sprayed by fresh influenza cultures (Pfeiffer) and two of them developed definite rhinopharyngeal colds within twelve hours. The symptoms lasted for a few

⁹ Between February and May more than seven physicians and inpatients have used the vaccine.

⁴ The League of Nations Epidemiological Report shows that about 300,000 cases of whooping cough were reported in the United States during 1932. A recent U. S. Public Health Service report shows that about 95 per cent of our 1,000 or more annual whooping cough deaths occur before the third year of life. About 2 per cent of all infected children succumb, but the mortality for infected infants is about 15 per cent. Because of its greater prevalence, whooping cough causes as many deaths as does diphtheria or as many as do scarlet fever and measles combined.

days. Cultures from their nostrils and pharynx showed the same type of bacilli that was sprayed on them, and these remained prevalent for several days and then gradually disappeared in the course of the next two weeks. I am one of those who believe that many persons after exposure to chilling develop a common cold. It seems to me that persons have the very contagious colds. These are usually due to the filtrable viruses. Persons have also some endogenous infections from their own organism and some contract colds, which are probably not due to the filtrable viruses.

DR HOBART A. REIMANN, Minneapolis. Considering the enormous amount of research, progress in the specific treatment of infectious disease has been relatively meager. The greatest success has been attained with the use of antitoxin, especially in diphtheria, tetanus and scarlet fever. There have been, however, many disappointing results, especially with tetanus and even with diphtheria. It appears that in botulism, for example, different strains exist for which different antitoxins are necessary. This problem was recently found by Blake and Trask to apply also to scarlet fever. These studies probably explain the occasional failure in specific antitoxin therapy and show that various strains require specific antitoxins of their own. It is too early to become enthusiastic over the use of bacteriophage, at least for generalized infections. Certainly it should not be exploited commercially or used indiscriminately. No evidence is at hand of its lytic action *in vivo*. Evans and others have shown that bacteriophage is inactivated by blood, pus, ascitic fluid and saliva. Its concentration after injection into the blood is far too weak to justify the expectation of specific lytic action. The belief that bacteriophage may be of specific value because recovery occurred in seven of fifteen treated cases of staphylococcal bacteremia, as reported previously by Dr MacNeal, is unconvincing, as in my experience recently the mortality from this infection was about 60 per cent in untreated cases. The favorable results of vaccine prophylaxis of whooping cough reported by Dr Sauer together with the reports by Lawson and Krueger and Smythe are most encouraging and may assist in establishing the etiology of the disease. Although the weight of evidence appears to favor *Bacillus pertussis*, a number of investigators have suggested a filtrable virus as the causative agent.

DR RAYMOND P. SCHOWALTER, Milwaukee. A few years ago I made a study of statistics pertaining to pertussis from the Milwaukee County Home for Dependent Children covering a period of sixteen consecutive years. During the first eight years of this period no children received pertussis vaccine while during the following eight years every child under 6 years of age was given pertussis vaccine or pertussis immunogen as a routine. The injections were given to 2,700 children, nevertheless there were more than twice as many cases of pertussis per thousand children during the period that vaccine was used than there were during the period when no vaccine was used. Dr Sauer seems to have found a method of preparation and a method of administration of pertussis vaccine that will protect a child from whooping cough just as certainly as toxoid protects against diphtheria. His success in immunizing against pertussis is probably due to two factors. The first factor is the preparation of the vaccine. He uses only fresh cultures obtained every few months from active proved cases of pertussis. The second contributing factor is the tremendous dosage. With the various commercial preparations a prophylactic course of injections utilizes from 7 to 27 billion organisms, depending on which preparation is used. In Dr Sauer's course of prophylactic injections 80 billion killed pertussis bacilli are injected into each child. At the Milwaukee County Home for Dependent Children, seventy-five children ranging in age from 6 months to 2 years have recently received Dr Sauer's vaccine. There was some local reaction and fever on the day following the injection. The reactions were similar to those encountered with some of the commercial vaccines formerly used. If no pertussis epidemic develops before the necessary four months has elapsed between the last injection and the exposure, it will be possible to arrive at some definite ideas regarding the efficacy of the vaccine.

DR PAUL S. RHODES, Evanston, Ill. Certain questions about antitoxin still arise. Will it do more than simply lessen toxemia? Will it be effective in preventing septic complica-

tions? Dr Hunt's figures show that, even when given late antitoxin materially reduces the morbidity and mortality in septic cases. If enough antitoxin is given early, septic complications rarely develop. Gordon asserted that immunotransfusion of from 100 to 500 cc of blood from convalescent scarlet fever patients is superior to antitoxin in severe septic cases. His results do not bear out this contention. Among 119 cases of severe septic type treated by immunotransfusion in Gordon's series there were 19 fatalities. In Hunt's series treated by antitoxin 14 of 120 septic patients died. In ten of Hunt's fatal cases antitoxin was given after the fourth day of illness. I have recently determined the antitoxic titer of ten pooled lots of convalescent scarlet fever serum. The highest potency obtained was 500 neutralizing units per cubic centimeter. No market samples of commercial preparations tested had a potency under 15,000 neutralizing units per cubic centimeter. These tests indicate that to give a patient as much antitoxin as he receives in a therapeutic dose of commercial antitoxin, usually 15 or 20 cc of concentrated and refined horse serum, one would have to give 600 cc of convalescent serum. At the Serum Center of Michael Reese Hospital in Chicago convalescent scarlet fever serum is distributed in doses of 20 cc for therapy and 10 cc for prophylaxis. The data just given, and also clinical trial show that this dosage is inadequate. Even 20 cc of convalescent serum seldom renders a susceptible person Dick negative. I have observed persons receive this dose and develop scarlet fever one or two days later. In my experience a prophylactic dose of scarlet fever antitoxin 100,000 neutralizing units has always rendered susceptible persons Dick negative within twenty-four hours. It has never failed to afford complete passive protection when given before the rash. In Gordon's series in which up to 80 cc of convalescent serum was used therapeutically the results were better than in untreated cases but not so good as in cases in which scarlet fever antitoxin was given. There is a quantitative element in the use of scarlet fever antitoxin that must not be neglected.

DR WALTER M. SIMPSON, Dayton, Ohio. The methods employed by Dr Foshay in the preparation of the detoxified suspension for the intradermal diagnostic test and the desensitizing antitularense serum represent a distinct departure from the methods and principles commonly employed. I have been able to confirm the specificity of the skin test in all of twelve recently encountered serologically confirmed cases of tularemia. In six instances Foshay's antitularense goat serum was used in the treatment of the disease. When contrasted with observations on more than 100 untreated cases observed in Dayton the prompt subsidence of the prominent symptoms and signs, particularly as related to the fever curve and the regional adenopathy left little doubt as to the efficacy of the treatment. In all but one, however, there was recurrence of the fever and glandular enlargement and in three instances surgical drainage of the regional suppurative adenitis was required. Because of the desire to observe the effect of a single intravenous injection of the antiserum, a second injection was not given. Preliminary observations with this small number of cases led to the conclusion that (1) the antitularense serum of Foshay apparently exerts a specific favorable influence on the disease, (2) at least two or three injections of the antiserum will probably be required in most cases, (3) the intradermal diagnostic test should be employed in the first week or ten days of the disease in order that the antiserum may exert its greatest benefit in lessening the morbidity and mortality.

DR GILBERT J. LEVI, Memphis, Tenn. In 1926 the *Tennessee State Medical Journal* published my report of 102 cases of scarlet fever treated with Squibb's scarlet fever antitoxin. At that time I also ran a control series and likewise a series of cases treated with Dochez's antitoxin. The results were uniformly better in the group treated by Squibb's antitoxin. Up to the present I have treated 600 cases. Since 1926 I have employed scarlet fever antitoxin in every case. I have had uniformly good results. The percentage of serum sickness was 30.5. With the administration of antitoxin of any type epinephrine hydrochloride, 1:1,000 solution was used. Complicating mastoiditis and nephritis have been conspicuous by their absence.

DR LUKE W. HUNT, Chicago. In answer to Dr Park's question as to why antitoxin was not given in many of the

mild and moderately severe cases, I must say that for some time after the development of the antitoxin it was given to only the sickest patients. Later it was given to all acutely sick patients and still later to all patients admitted to the hospital soon after the development of the disease. In scarlet fever immunity whether occurring spontaneously or produced artificially by the injection of toxin or by the injection of antitoxin there is a quantitative element which must be taken into consideration if one is to obtain the best results.

DR WARD J. MACNEAL, New York. I think that the question of the effectiveness of the bacteriophage in infections of the blood stream is not yet ready for final decision. A stock bacteriophage is first used in the bacteremia cases, because in most instances it is feared that death will occur within twenty-four or forty-eight hours. At the same time the culture that has been obtained from the blood stream is being studied and at the earliest possible moment an auto-genous filtrate is substituted. Sometimes it happens that the stock bacteriophage proves to be worthless. Usually by that time the patient has died. The serum is prepared in the laboratory of the state department of health of New York under the supervision of Dr. Augustus Wadsworth. He designates it as concentrated streptococcus serum for experimental purposes. It is not available for general distribution and has been given out to a limited number for experimental work. It appears to be an exceedingly valuable serum. I have used it almost exclusively in doctors, nurses, laboratory workers and members of their families.

DR LOUIS W. SAUER, Evanston, Ill. In regard to Dr. Park's question as to an explanation for the difference between Dr. Madsen's results and mine, I wish to say that my vaccine differs from all other pertussis vaccine. It is made only from recently isolated strains and is grown only on human blood. The dosage is at least three times that of any other dosage and the time interval is probably the most important factor. Three or four months should elapse or intervene between completion of the vaccine administration and exposure to the disease. During the five years that this work has been going on, people wanted their children injected while whooping cough was in their neighborhoods. This was done and in a number of cases within one or two months after the injections were begun, these children contracted pertussis. But in no case in which the time interval was more than three months has any child contracted pertussis, although as the charts show, eighteen were intimately exposed to control cases in the family. In regard to a filtrable virus, I am well aware that several investigators have brought up the question of intracellular inclusion bodies. When one remembers that the mortality of pertussis is between 1 and 2 per cent, that it is a relatively benign disease, the question of finding intracellular inclusion bodies at autopsy of the relatively few patients who die is a far jump from making it an etiologic factor. Indeed, these very experiments of active immunity induced by vaccine made of the Bordet-Gengou bacillus are I believe the strongest argument against the now fashionable filtrable viruses. In regard to Dr. Rhoads' question a few agglutination tests were performed, but I believe that immunity and agglutination or complement fixation are not the same things. The height of an agglutination or complement fixation test does not imply that the highest immunity is then reached. The wonderful work on agglutination in Denmark shows that children getting as small a dose as 22,000,000,000 developed an agglutination peak a few weeks after the administration of vaccine. But the same children exposed within one to three months all contracted the disease. In the preliminary work a great number of white cell counts and differential counts were made before the vaccine was administered and then on the day of the first injection. A number of children had white counts that reached or exceeded 50,000. The lymphocytosis in many of the cases was almost that of pertussis.

DR ILL. FOSHAY, Cincinnati. I should like to suggest to Dr. Sauer that he try one of the methods of chemical detoxication in his pertussis suspension, that Dr. Wherry and his associates used in Cincinnati. I feel certain that if the proper chemical is found he will be able to inject the same amount of bacteria and have less constitutional reaction without impairing the antitoxic or immunizing properties of his suspension.

It is quite probable that formaldehyde half saturated urea or nitrous acid would work very well. My answer to Dr. Park's question is that at the time I began the goat was the largest animal I could find space for. Sheep make a good antitularense serum and this year I have what seems to be a very good antitularense serum in the horse. I have no illusions that the antiserum as made so far is the best that can be prepared. Having eliminated some of the variables as to manner of production and manufacture and preservation, I believe that I am following what Dr. Simpson indicated in his discussion, namely, that the patients need more serum. I know now that half of my patients did not get enough serum. When I compare the patients in whom I used two doses, each time from 15 to 18 cc. with the control group I find that the duration of the disease was reduced by 75 per cent.

DR YALE KNEELAND, Jr., New York. I think Dr. Park is right. There is such a thing as a pure bacterial cold. Our observations on filtrable viruses and our general hypothesis as to the etiology of these disorders are based on the ordinary outbreaks of highly communicable upper respiratory disease.

CONGENITAL OBSTRUCTION OF THE SMALL INTESTINE

WILLIAM E. LADD, M.D.

BOSTON

This paper is based on a study of sixty cases of congenital intestinal obstruction occurring in the Children's Hospital of Boston. Only those cases are included in which the obstruction was located in the small intestine and was due to one of two factors. Intrinsic obstruction is the interference in the continuity of the lumen of the intestine due to intrainstestinal defects. Extrinsic obstruction is the interference in the function of the intestine by external pressure due to faulty rotation. Obstruction caused by bands which may or may not be of congenital origin and that due to hernias and the vagaries of Meckel's diverticulum are not included.

EMBRYOLOGY

To understand these conditions one must consider the normal embryologic development of the intestine. Most of the embryologic events take place between the fifth and tenth weeks of fetal life. Prior to the fifth week of fetal life the intestine presents a well defined round lumen lined with epithelium. Soon after this the epithelium rapidly proliferates and the lumen of the intestine becomes obliterated by epithelial concrescence. This solid stage persists for a short time until vacuoles appear and coalesce to reestablish permanently by the twelfth week of fetal life the intestinal lumen. An arrest in development during this period results either in atresia of the intestine at one or more points or in stenosis. The atresia of course is due to complete lack of continuity with a blind end or to a remaining imperforate septum (fig. 1) while the stenosis is due to a remaining but perforated septum. The intestine above the point of obstruction becomes dilated while that below remains collapsed. In cases of atresia the intestine below the point of obstruction appears as a small cord though it has all its normal elements including a lumen. This lumen, never having had any anatomic fluid in it to dilate it, remains only large enough to admit a small probe. In cases of stenosis the intestine below the point of obstruction remains small but not as small as in cases of atresia. In the

From the Surgical Service of the Children's Hospital, and before the Section on Surgery, General and Abdominal at the First Fourth Annual Session of the American Medical Association, Milwaukee, June 16, 19.

cases with a complete lack of continuity of the bowel, the blind ends may be multiple. This condition is less easily explained by an arrest in normal embryologic development.

The cases of extrinsic obstruction due to faulty rotation present a variety of conditions which are extremely confusing unless one remembers the normal process of rotation through which the bowel goes. After the fifth week of fetal life the liver and other contents of the abdominal cavity grow much more rapidly than the cavity itself. Nature meets this situation by forcing the midgut into the base of the umbilical cord. By the tenth week of fetal life the return of the midgut loop to the abdominal cavity has begun. The pre-arterial segment, which includes the small intestine from the duodenum to the vitelline duct, returns first and passes from the right to the left side behind the superior mesenteric artery. The terminal ileum, cecum and ascending and transverse colon follow and cross in

seven female patients. There were twenty cases of obstruction due to abnormal rotation and forty cases due to intrinsic defects. The site of obstruction was in the duodenum alone nineteen times, in the jejunum eight times, in the ileum twenty-seven times and in more than one site six times.

DIAGNOSIS

The predominant symptoms in patients with congenital intestinal obstruction, as with any form of intestinal obstruction, are pain or discomfort, vomiting and lack of stools. Among the prominent signs may be mentioned abdominal distention, visible peristalsis or coils of intestine, evidence of shock, dehydration and ketosis. In the particular group of cases under consideration there are exceptions to the usual findings in individual cases. Thus there are patients with duodenal atresia in whom the vomiting was so effective that the stomach and duodenum were completely emptied, and the distention and visible peristalsis were lacking. Likewise in those patients with volvulus of the midgut the obstruction takes place first at the duodenal end so that distention is not marked.

It is of course, highly desirable for technical reasons to make as accurate a diagnosis as possible before the operation is undertaken. The examination of the stool and a roentgen examination without, as well as with, the administration of contrast mediums are of great assistance in this respect. One remembers that meconium begins to collect in the intestine after the third month of fetal life and that any atresia that has taken place prior to this time precludes the possibility of finding the normal elements of meconium in the stools. The normal elements of meconium consist of mucus, bile, keratinized epithelial cells, lanugo hairs and vernix caseosa swallowed with the amniotic fluid. Of these elements the easiest to recognize, and one that is constant, is the keratinized epithelium. This may be detected satisfactorily in a smear dried with ether, stained with Sterling's gentian violet for one minute and decolorized with acid alcohol. Failure to find these keratinized epithelial cells in the stools is an indication that one is dealing with a case of atresia, as pointed out by Dr. Sidney Farber, pathologist of the Children's Hospital. If an x-ray plate of the abdomen is taken without the administration of any contrast medium, the point of obstruction, if complete, is clearly identified by the outline of the gas above the blind end (fig 2). In fact, the administration of barium is contraindicated if one suspects complete obstruction as it tends to block the small lumen below an anastomosis. If a flat plate has demonstrated gas distributed throughout the abdomen and the child is not too ill, barium may be given and valuable information obtained.

TREATMENT

When the diagnosis of obstruction has been made, there should be no delay in instituting surgical treatment. The patient is prepared for operation by the administration of parenteral fluids to counteract dehydration and ketosis. A right rectus or right paramedian incision is made high or running above and below the umbilicus, according to the site of the obstructing lesion. For patients with intrinsic duodenal obstruction it is my belief that a duodenojejunostomy is preferable to a gastrojejunostomy. This belief is based on experience with one patient on whom a gastrojejunostomy was performed when she was 6 days old. She required a duodenojejunostomy at the age of 7.

Fig. 1—The septum across the duodenum (a) the result of arrest of development at the solid stage (b) duodenojejunostomy for relief of the duodenal obstruction caused by (a)

front of the superior mesenteric artery from left to right. This leaves the duodenum behind the superior mesenteric artery and the rest of the midgut lateral to or in front of it. At this stage of development the midgut is attached to the posterior abdominal wall by a very small pedicle at the origin of the superior mesenteric artery. An arrest of development at this stage leads to the postnatal complication of volvulus of the midgut. The next stage consists in the mesentery of the intestine becoming fused with the parietal peritoneum, giving the small intestine its normal oblique attachment and the cecum and ascending colon their normal stabilizing attachment to the right side. Abnormal attachment of the intestine to the posterior abdominal wall leads to a variety of conditions causing intestinal obstruction.

INCIDENCE

In this series of sixty cases, the incidence showed the slight predominance of thirty-three male to twenty-

months for the relief of duodenal stasis, even though the gastrojejunostomy stoma was open and functioning well. Complete relief followed the second operation. Of course, it must be admitted that a gastrojejunostomy is a much easier operation to perform, but should only be employed when the infant's condition does not warrant the preferable operation of duodenojejunostomy.

In these small infants the anastomosis itself demands special technique. The distal loop is so small that it must be dilated before an anastomosis can be performed. This dilation may be accomplished with air, as recommended by Clogg¹ in 1904 and by Webb and Wangenstein² in 1931, or following the technique I have used. This technique consists in opening the lower loop, dilating it with a small catheter and completing most of the anastomosis before the catheter is withdrawn (fig 3). The distal loop is too small to allow more than one row of sutures, and these must be of very fine silk. One row of Connell sutures of the fine silk intended for anastomosis of the blood vessels has proved adequate. This technique is also used for anastomosis when the atresia is lower in the intestine. It should be remembered that it is worth while performing an anastomosis even when the distal end of the bowel looks too hopelessly small to function. It acquires an adequate lumen much more quickly than seems possible after fluid has entered it (figs 4 and 5). In cases of atresia the blind end tends to perforate especially when it is situated low in the intestine. There have been eight such cases in this series. It has been stated that these patients never recover following enterostomy. There are exceptions to all rules, and in our series there is one patient who had perforation in the terminal ileum and diffuse peritonitis. This patient had a resection of 4 or 5 inches (10.16 or 12.7 cm) of terminal ileum with an enterostomy when 7 days old, and at a later date an ileocolostomy was performed, with recovery. As a general rule, however, it is more desirable to perform an intestinal anastomosis at the first operation. One then relies on fluid from above as well as saline enemas for dilation of the distal segment. The combination is much more effective than the enemas alone.

Certain procedures are essential to treat obstruction due to faulty rotation successfully. The whole midgut must be delivered to show what type of operation is required. It must be remembered that a volvulus in a clockwise direction is the more common but it may take place in an anticlockwise direction. Reduction

of the volvulus is the first stage of the operation and has, in my experience, caused temporary relief but not cure. After the volvulus has been reduced, any attachment of colon or ileum to the right of the duodenum is freed until the duodenum is entirely in view and lies to the right of the cecum and terminal ileum. In every case in my series in which this has not been done there has been recurrence of the obstruction. In no case in which this has been done has there been a recurrence. There are other cases of obstruction due to faulty rotation which are not associated with volvulus. In some instances the rotation has proceeded to a point at which the cecum becomes attached to the posterior abdominal wall and impinges on the duodenum at its point of crossing. In other instances one section of the intestine appears to perforate the mesentery of another section, and obstruction is caused at this point. The latter condition is likely to be erroneously considered as a hernia. Both of these conditions have been relieved by incision of the posterior parietal peritoneum on the right side and transference of the portion of the intestine causing the obstruction to the left. In other words, an earlier state of embryologic development is restored.

REPORTS OF TYPICAL CASES

One case report of each type is given to illustrate more specifically the conditions actually found.

CASE 1—Duodenal Obstruction Due to Malrotation—T. C., an 11 month old male infant, was admitted to the medical service because of daily vomiting since birth. The vomiting occurred a few hours after each feeding, was in the form of regurgitation and totaled about 100 cc each time. The vomitus was of fluid consistency and bile-stained. In spite of the repeated vomiting, the patient gained weight until the tenth month, but after that time he failed to gain.

Physical examination gave negative results. Barium sulphate was given by mouth, and a partial obstruction of the duodenum due to malrotation of the colon was found. The patient was discharged home on the parent's request and returned in two weeks for a second barium study which showed the same condition. Surgical intervention was advised. At this time the baby had lost 1½ pounds (0.7 Kg) of his maximum weight and seemed to be distinctly regressing. Physical examination showed slight visible peristalsis in the epigastrium and little else of note.

Operation revealed the stomach to be slightly enlarged, the pylorus patulous and the duodenum markedly dilated. The cecum was attached in the right upper quadrant at about the level of the kidney and impinged on the duodenum causing intermittent obstruction. The cecum was delivered into the wound and by dissection, freed from the posterior peritoneum so that it could be pushed to the midline, thus exposing the duodenum throughout its entire length. At the duodenojejunal junction there was a definite constriction formed by malattachment of the cecal mesentery. Freeing of this and moving the cecum to the midline completely relieved the obstruction.

Following operation the patient had a stormy course, the temperature remaining around 105 and 106 F for four days. This was due to continued vomiting, resulting in dehydration which was combated with intravenous injections of dextrose and subcutaneous hypodermocenteses of saline solution. On the

Fig 2—Roentgenogram from the same case as figure 1 showing clearly the point of obstruction in the duodenum without the ingestion of contrast mediums.

Fig 3—Technic of anastomosis with a single row of fine silk sutures and the insertion of a catheter for dilating the distal segment.

² Webb, C. H. and Wangenstein, O. H. *Congenital Intestinal Atresia*. *Am. J. Dis. Child* 12: 66 (Feb) 1931.

fourth day after operation, the vomiting ceased, the temperature became normal, and the bowels moved freely. From that time on all feedings were retained, the bowels moved normally, and the patient progressed satisfactorily. At the end of the first week the patient had gained 14 ounces (0.43 Kg). The last report, six months later, stated that the child was in excellent health, was gaining weight and apparently was normal in every respect.

CASE 2—Duodenal Obstruction Due to Intrinsic Stenosis—B. S., a 6 day old female infant, was admitted to the Children's

Fig. 4—The jejunal blind end distended bowel above and rudimentary collapsed bowel below

Hospital because of vomiting since birth. The vomitus at first consisted of ingested food which was bile-stained. Two days before entry the vomitus contained frank blood for which a transfusion of citrated blood was given. Meconium was passed during the first forty-eight hours, but from that time on there had been no stools. Parenteral fluids had been given for four days before entry. On admission, examination revealed a full epigastrium and an empty hypogastrium. There was visible gastric peristalsis. Roentgen examination showed a

dilated duodenum and stomach with a very small amount of gas in the rest of the intestine. Operation was advised and performed after the administration of more parenteral fluids.

At operation the jejunum was found to be collapsed, while the duodenum that could be visualized was markedly dilated. The patient was in such poor condition that a duodenojejunostomy was not attempted. A gastro-enterostomy was performed in the usual manner and the patient returned to the ward in poor condition.

Parenteral fluids were continued for two days after operation to supplement the limited feeding. At the end of forty-eight hours the baby began to have normal stools. She gained weight steadily and was discharged one month later.

The patient did well for seven months. At that time she became anorectic and failed to gain weight. Feedings were changed but the situation remained the same. The patient was admitted to the hospital for further study. Barium given by mouth, entered the stomach readily and passed out through the stoma without difficulty. However, some of the barium entered the duodenum churned back and forth, and returned to the stomach. Gastric analysis revealed achlorhydria. Variations in the diet, with the administration of brandy to stimulate the secretion of hydrochloric acid, were given. As twenty days of this regimen resulted in no improvement, and as it was thought that the regurgitation of duodenal contents into the stomach caused the anorexia, further operative relief was advised.

At the second operation a duodenojejunostomy was performed. Following this procedure the patient gained weight rapidly and had no more difficulty. The last report, two years later, revealed the baby to be in excellent health and having no symptoms of gastro-intestinal disturbance.

CASE 3—Duodenal Obstruction Due to Intrinsic Stenosis—H. G., an 8 year old girl, entered the hospital because of loss of weight, anorexia and discomfort in the abdomen. She had been apparently well until one year before entry, except for measles at 4 and pertussis at 5 years of age. One year before entry she began complaining of discomfort in the epigastrium, most marked after eating, belching of gas of bad odor and entire loss of appetite. The stools had been small and constipated. She had lost 15 pounds (6.8 Kg) during the year and 10 pounds (4.1 Kg) in the two weeks prior to entrance, in spite of having had excellent medical care. The patient

was listless and obviously was somewhat under normal weight. Nothing abnormal was found on examination except fulness in the epigastrium with a suggestion of gastric peristalsis following the ingestion of fluid. Roentgen examination showed a dilated duodenum with to and fro peristalsis and retention indicating duodenal stenosis.

At operation a dilated pylorus and duodenum were found, the obstruction being intrinsic in the third portion. A duodenojejunostomy was performed. The convalescence was untroubled.

Three months later the patient was reported to have a good appetite and no epigastric distress or belching, and to have gained 20 pounds (9 Kg).

CASE 4—Jejunal Obstruction Due to Intrinsic Atresia—R. K., a 7 day old female infant, born one month prematurely entered the hospital because of vomiting all of her feedings since birth. The epigastrium became markedly distended after each feeding, which was succeeded by vomiting and subsidence of the distention. The vomitus was consistently bile-stained. For the first two days meconium was passed by rectum but since that time there had been no stools. The birth weight had been 5 pounds and 9 ounces (2.57 Kg) and had decreased in seven days to 4 pounds and 2 ounces (1.86 Kg).

Physical examination revealed a well developed, premature, apathetic infant with loose wrinkled skin and very little subcutaneous fat. The epigastrium was distended and the hypogastrium empty. Intestinal patterning and visible peristalsis were noted in the epigastrium. A roentgenogram taken on admission showed a markedly dilated stomach and duodenum. There was no gas in the lower portion of the small intestine or in the large intestine. An intravenous injection of dextrose, 10 per cent, and a hypodermoclysis of saline solution were given immediately and repeated in six hours.

Exploratory laparotomy was then done, and a complete atresia of the first portion of the jejunum was found 3 cm below the first atresia was a second atresia. A jejunojunostomy was then done between the dilated and the collapsed loops. Following operation, daily administration of parenteral fluids kept up the correct intake of fluid. For the first six days

Fig. 5—From the same case as figure 4 showing the normal size of the bowel below the blind end. This was produced in two months as the result of anastomosis and distending enemas.

the baby vomited practically all of her feedings and passed nothing by rectum. Enemas were given every four hours for the purpose of dilating the colon. During this time she had lost weight to 3 pounds and 8 ounces (1.6 Kg). On the evening of the sixth day a large, formed stool containing digested food and bile was passed. From that time on the baby took her fluid well, had normal stools and gained progressively. Feeding was extremely difficult in this infant and consisted of half whey and half breast milk until the eighth day, when the whey was decreased by

drachm amounts until she was able to take 1½ ounces (45 cc) of breast milk every three hours, at the end of two and a half weeks after operation.

The patient continued to gain and was ready for discharge at the age of 2½ months, when she acquired a respiratory infection which developed into diffuse bronchopneumonia; she died four days later. Autopsy revealed the intestine, which was found collapsed at operation to be well dilated and the anastomosis to be functioning perfectly.

RESULTS

In the literature hundreds of cases are reported, but the vast majority of them are postmortem observations from patients who had either been unsuccessfully operated on or who died before operation was performed. In 349 articles, however, are found the reports of 15 patients in the age group in this article (from birth to 12 years of age, inclusive) with obstruction of the small intestine due to malrotation, who have been

successfully treated by operation. Four cases are reported by Waugh,³ two by Green⁴ and one each by Higgins,⁵ Rixford,⁶ Ombredanne,⁷ Lee and Nye,⁸ Kotzareff,⁹ Jewsbury and Page,¹⁰ Foisy,¹¹ Frank,¹² and Davis.¹³

In these articles are also reported histories of fourteen patients with atresia or stenosis of the small intestine who recovered following operation. In every instance the operation was a primary anastomosis. Weeks and Delprat¹⁴ Bolling,¹⁵ Ernst¹⁶ and Richter¹⁷ each reported one case of duodenal atresia, Sweet and Robertson,¹⁸ one case of jejunal atresia, and Demmer¹⁹ and Fockens,²⁰ each one case of ileal atresia all with recovery. Loitman²¹ reported from the literature two cases of duodenal atresia with recovery which appeared to be wrongly classified. Cole²² reported three cases of duodenal stenosis relieved by gastro-enterostomy. Dubose,³ Downes²⁴ and Cameron² each reported one case of duodenal stenosis and Rotter²⁵ one case of ileal stenosis with recovery.

In my series of sixty patients there were twenty in whom the obstruction was due to malrotation. Of these twenty, nine recovered. The nine patients recovered as the result of the freeing operation described in this paper as the final procedure. Two of them had had a reduction of volvulus followed by recurrence of

the obstruction which required the freeing operation for permanent relief.

There were forty patients with obstruction due to intrinsic causes. Of these, eight recovered. In five patients the stenosis was in the duodenum, all of them were relieved by duodenojejunostomy. One of the patients had had a previous gastrojejunostomy which had given only temporary relief. One patient with ileal stenosis was cured by resection and ileocolostomy. One patient had an atresia of the jejunum. A jejunojejunostomy was performed, it afforded complete relief. However, this patient contracted pneumonia two months later and died. Autopsy showed the anastomosis to be functioning perfectly with dilatation of the distal segment to normal size. Another patient had an atresia of the terminal ileum with perforation and diffuse peritonitis. He had a resection of 4 or 5 inches of terminal ileum and an ileostomy performed on the seventh day of life. An ileocolostomy was done when he was 2 months old. He reported at the hospital when 1 year old and was well at that time.

SUMMARY AND CONCLUSIONS

I believe that these conditions are much more common than is usually supposed. This belief is founded on the fact that in a comparatively few years sixty patients with such conditions have appeared at the Children's Hospital, and from the fact that a large number of cases are reported in the literature.

If these conditions are kept in mind and adequately treated, a great many lives will be saved in the future which have been forfeited in the past.

TABLE 2—Operative Treatment of Intrinsic Obstructions

Site of Obstruction	Operation	Result	
		Deaths	Recoveries

Duodenum 1	Jejunostomy (for feeding)	1	0
Multiple 3	Unclassified	3	0
Total		32	8

Twenty-nine patients of the age group included in this paper are reported relieved in the 349 articles reviewed. In a series of sixty cases from the Children's Hospital of Boston a report of seventeen more patients who have been relieved is added.

ABSTRACT OF DISCUSSION

DR. ALBERT H. MONTGOMERY, Chicago: The etiology of congenital obstruction of the small intestine has been ascribed to errors in the development or to disease of the fetus. Dr. Ladd's series of cases is restricted to those in which the obstruction is due to errors in development such as failure of normal canalization of the intestine and improper rotation. These imperfections in development are obviously the logical explanations in most of the cases. To these may be added the suggestion of Bland Sutton that the obstruction is associated with the site of an embryologic event such as the place of attachment of the vitelline duct and the second portion of the duodenum where the liver and the pancreas form. There is, however, a smaller group of cases in which the occlusion is probably due to some disease of the fetus. Knox has called attention to congenital adhesive bands. In other cases fetal peritonitis may be present. Cases of aplasia may be due to an intra-abdominal accident before birth which produced a tear of the intestine and its mesentery leaving a definite defect in

both. In regard to the diagnosis, it would seem rational to assume, with Dr Ladd, that the absence of cornified cells from the stools is indicative of an obstruction somewhere along the alimentary tract. The use of the x-rays is important, but I think a word of warning should be given. The diagnosis can be made in most instances without them, and there is a very definite possibility that the barium may cause obstruction in cases of stenosis with a small opening. It is almost impossible to wash out this barium, and if an anastomosis is necessary it is very disadvantageous. The outlook for these cases will always be doubtful but Dr Ladd has shown that with an early and careful diagnosis a fair percentage of them can be cured. The most hopeful cases are those presenting obstruction due to congenital bands that merely require incision. Duodenal obstructions that can be relieved by an anastomosis offer a fair prognosis. For those situated in the jejunum or ileum the outlook is not so good. Too often the malformation of the intestine precludes any type of curative operation. I am quite in accord with the treatment that he has outlined in the cases of faulty rotation. It is founded on sound surgical principles, as the results clearly indicate. One could hardly disagree with the work of a surgeon who can show such outstanding results in these difficult cases.

DR W. H. COLE, St. Louis. At the St. Louis Children's Hospital, during the past fifteen years, there have been twenty-four instances of intrinsic obstruction of the small intestine. All the patients except one were operated on, but only six survived the operation. In the group of twenty-four cases, the obstruction occurred at the duodenum in nine instances. The obstruction in this duodenal group was due to a stenosis in four instances. A gastro-enterostomy was performed in all four instances, with three survivals. It could not be determined whether the obstruction was complete in these three cases but the evidence was quite convincing that it was in one instance. In the remaining cases of duodenal obstruction four of which were due to congenital bands, the patients died following operation. However, on the four occasions in which the obstruction was produced in the terminal ileum by a congenital band, two of the infants survived. Atresia with interruption of the intestinal wall occurred five times in the ileum (in one instance was multiple) and once in the duodenum and jejunum. Four of these seven patients were treated by anastomosis and three by ileostomy, but none survived. On one occasion a stenosis of the pylorus was encountered. A plastic operation was performed and the infant survived. Two patients with unperforate diaphragm of the ileum and one with perforate diaphragm were operated on but all died. Perhaps the most remarkable case in our series was one of atresia of the ileum 10 inches above the cecum in which operation was performed by Dr N. A. Womack. A cystic mass 10 cm. in diameter was found in the mesentery near the blind loops and was attached by a fibrous cord to the proximal loop. At autopsy, performed by Dr Margaret Smith, numerous short interrupted coils of tissue about the size of the distal loop of intestine were embedded in the wall of the sac. On cut section some of these coils revealed a lumen, and microscopically, intestinal mucosa was found. It seems probable that several inches of ileum became intussuscepted into the vitelline duct early in fetal life and were pinched off when the continuity of the vitelline duct with the ileum was destroyed. On three occasions an incomplete obstruction of the duodenum produced by malrotation was found. Two of these three infants survived operation.

DR FRANK K. BOLAND, Atlanta, Ga. A woman, aged 44, the mother of two children, who had enjoyed fair health most of her life, had an occasional attack of indigestion and vomiting. About a year before I saw her another surgeon made the diagnosis of duodenal ulcer and a posterior gastro-enterostomy was performed. There was no history of any particular trouble in infancy. She was better for a few months after which she began to vomit again and to lose weight. When I first saw her she weighed 70 pounds (32 Kg.) and two thirds of a barium meal remained in her stomach after six hours. Following a blood transfusion the abdomen was opened and a thickened pylorus was made out, which was thought to be either an ulcer or persistent hypertrophic obstruction. The patient's condition was bad and only an anterior gastro-enterostomy was done. At first the reaction was violent the

patient vomiting constantly. With the use of continuous saline and dextrose venoclysis, as practiced by Hendon, the condition grew better and the patient was able to take food. By the eleventh day she had improved so much that she was talking about going home, when suddenly she had a severe coughing spell and began vomiting again, fever, abdominal pain and distention developed, and the patient died the next day. Autopsy showed that there was no obstruction at the pylorus or at either gastro-enterostomy and that no duodenal ulcer was present. The abdomen was filled with fluid and there was leakage through the last gastro-enterostomy. Death was due to peritonitis. Further examination revealed that the lumen of the lower half of the ileum had a diameter of only 1.5 cm. about large enough to admit a lead pencil. Microscopic section of this part of the intestine showed that its walls and glands were perfectly normal, like those of the rest of the ileum. As the ileum approached the cecum it increased in size, so that it was normal at the ileocecal valve. Apparently the patient's pyloric obstruction was due to spasm.

SURGICAL CONSIDERATIONS OF CARCINOMATOUS METASTASES TO THE BRAIN

ERIC OLDBERG, M.D.
CHICAGO

In 1926, Francis Grant¹ in a review of the forty-nine cases of intracranial malignant metastases which had been seen in the service of Dr. Harvey Cushing up to that year, concluded that "Surgery, whether radical or palliative, is of no ultimate benefit to these patients so far as prolongation of life is concerned." He felt justified in making this conclusion because his statistics showed that the average period of survival from hospitalization to death of persons afflicted with such lesions was three months, irrespective of whether the metastases were treated, decompressed or left alone. A further study from the same clinic in 1931 by Meagher and Eisenhardt² lent weight to his figures by showing that of the ten cases in which the primary focus lay in the breast, the longest period of survival following operation was five months, the average being six weeks.

Since the publication of these papers a case has been administered to throughout its cycle in Dr. Cushing's clinic, which has seemed to invite examination of the records subsequent to 1926 for others like it with a view to possible anchoring of the nihilistic philosophy for which there was firm foundation at the time of Grant's report. The case in question follows:

CASE 1—Removal of carcinoma of the right breast fourteen months before admission. Development six weeks before admission of headache, semistupor, choked disk, left abducent palsy, right hemiparesis. Operation with complete extirpation of a left parieto-occipital metastasis. Death two years later. Necropsy, showing no intracranial recurrence.

Past History.—Sarah MacQ., an American housewife, aged 52, was admitted to the hospital on April 21, 1930, having been referred by Dr. D. L. Lionberger of Rosindale, Mass. On Feb. 4, 1929 (fourteen months before this admission), a radical mastectomy was performed at the Forest Hills Hospital for carcinoma of the right breast, which was first noticed three months previously. The microscopic report on the tumor tissue, made by the Boston Dispensary Laboratory Department, was that the tumor was made up mostly of atypical epithelial

Read before the Section on Nervous and Mental Diseases at the Eighty-Fourth Annual Session of the American Medical Association, Milwaukee, June 16, 1933.

cells with practically no tendency toward gland formation, that it was of high malignancy and that two lymph nodes, simultaneously submitted, showed no evidence of metastasis.

Complaint and Examination—At the time of admission, the patient had been developing headache, right hemiparesis and aphasia for about six weeks. Examination revealed apathy, bilateral choked disks of 3 diopters and abducens palsy, hemiparesis, hemihyperesthesia, astereognosis, homonymous hemianopia and increased deep reflexes on the right. The Wassermann

Fig 1 (case 1)—Coronal section of the brain showing the dura adherent to the old operative scar. There was no sign of recurrence, either grossly or microscopically.

test of the blood was negative, as were all other laboratory tests, and roentgen examination of the skull showed nothing except displacement of the pineal body backward and to the right of the midline. Because of the suspected nature of the lesion, roentgen examination of the chest was also made, it showed no metastases.

Operation—Operation was performed by Dr Cushing on March 26, 1930, via a left parietal bone-flap, a surface tumor 5 cm in diameter and surrounded by highly vascularized cortex being exposed. The tumor was circumscribed by electro-surgical measures, and was enucleated in totality. A large decompression was made and the wound closed without drainage.

Grossly, the extirpated metastasis was about the size of a hen's egg, was soft and hemorrhagic and contained numerous small cystic areas. Microscopically, the tissue represented metastatic adenocarcinoma composed of large masses of epithelial cells which frequently formed definite acini. They were poorly supported by stroma, and a fair number of mitotic figures were seen. There were areas of degeneration and hemorrhage. The histology in general was that of adenocarcinoma, with metastasis from a primary source in the breast.

Subsequent Course—All of the patient's neurologic symptoms subsided rapidly after operation, and she was discharged on May 11 perfectly well and alert and with a soft decompression. The patient reported to the clinic on September 13, when it was noted that some of the supraclavicular glands which had been observed during the patient's hospitalization were enlarging, and she complained of some transitory swelling of the right arm. Her decompression was however, soft and she was without neurologic signs or symptoms. She was accordingly given roentgen therapy directed toward her right axilla and supraclavicular region and was sent on her way. She reported again on April 23, 1931, one year after operation, "feeling fine" and without signs of an intracranial recurrence.

Death and Necropsy—In the spring of 1932 the patient began to fail although she still had no evidence of intracranial metastasis and on June 4, 1932 she died. Autopsy performed at her home by Dr R. O. Good revealed extensive recurrences along the site of mastectomy, in the sternum and manubrium

in the superior mediastinum, especially on the right, and in both lungs. The mediastinal metastasis had compressed the innominate vein, pushed the trachea and all other mediastinal structures to the left and completely occluded the superior vena cava, this being the cause of death. The brain was removed and sent to Dr Cushing.

The Brain The entire brain was carefully sectioned coronally at intervals of 1 cm or less and no evidence of recurrence or other metastasis was visible. The site of extirpation of the old metastasis was depressed, and there was nothing visible except a puckered scar to which the overlying dura was adherent.

Here, then, was a case in which removal of a known malignant metastasis was attended by distinct benefit. This woman, who had entered the hospital totally disabled by hemiplegia and aphasia, was given two more years of useful and comfortable life, and, but for a recurrence of her original lesion, might have escaped much longer, if not permanently, from her misfortune.

This gratifying result inspired further inquiry, with prompt disclosure of the following case history.

CASE 2—Development within four months of headache, blurred vision, choked disk, loss of memory and dulled cerebration. Removal of left parieto-occipital tumor, proving histologically to be metastatic carcinoma from the lung. Alleviation from symptoms for nearly three years. Sudden death several days after secondary operation for enucleation of an intracranial recurrence.

Berth G., a Jewish widow, aged 46, was admitted to the medical service on April 6, 1925, from which she was transferred to the surgical service. For four months before admission she had increasingly severe frontal headaches, and to this symptom had more recently been added blurring of vision. Choked disk had developed, the patient had become mentally much dulled, and she had a right homonymous hemianopia. The pineal body was displaced to the right, and lumbar puncture, done in the medical service, disclosed xanthochromic fluid.

Operation and Course—On April 22 a left parieto-occipital cyst was punctured, and three days later Dr Cushing extirpated, apparently completely, a large fatty cystic tumor from this region.

Fig 2 (case 2)—Metastatic carcinoma of the brain.

Histologically, the tumor was obviously carcinoma, evidently metastatic from the lung, and postoperative roentgenograms of the chest revealed a rounded sharply defined mass, 5 cm in diameter, in the hilus of the left lung.

Following this procedure, the condition cleared up and the patient remained perfectly well for more than two and one-half years. She then began to have signs of recurring increased intracranial pressure and was readmitted to the hospital. On Feb 28, 1928 the old flap was reelevated and a huge cystic tumor larger than a tennis ball, was enucleated electrosurgi-

cally. Microscopic examination again showed metastasis from a probable bronchogenic carcinoma. The patient did well until March 5, when she was found unconscious; she died shortly afterward. Permission for autopsy was refused.

But for this patient's sudden and unfortunate collapse she might well have been expected to make a recovery as brilliant as her first one, for it is recognized that bronchogenic carcinomas may lie dormant for years.

A third case, though not possessing the spectacular elements of the first two, is cited here because it represents a survival of eight months following removal of a metastasis from a carcinoma of the breast—the longest previously reported survival being five months.

CASE 3—Radical mastectomy for carcinoma of the breast, one and one-half years before admission. Headache, vomiting, aphasia, choked disc and right homonymous field defects of four months development. Operation and removal of left temporal metastasis. Recovery with survival for eight months. Death.

Marion H., an unmarried woman aged 46, was admitted to the hospital on Jan. 31, 1931, having been referred by Dr. Edward P. Starbird of Dorchester, Mass. One and one-half years before admission she had had a radical amputation of the breast because of carcinoma. For four months before admission she had been developing headache, vomiting and expressive aphasia. Examination showed in addition bilateral early choking and right homonymous field defects.

Operation and Course.—On February 7 the patient was operated on by Dr. Cushing, who electrosurgically extirpated a partially cystic mass which was adherent to the dura in the left temporoparietal region. Histologically the mass proved to be metastatic carcinoma.

Following this operation the patient made a complete recovery, until shortly before Oct. 24, 1931, when she had a rapid recurrence of symptoms and died at her home.

It must be recognized that these three cases represent the only ones in a series of some fifty-four intracranial metastases, thirty-one of which have been operated on, in which the prolongation of life has been substantial. However, a careful analysis of the circumstances that in but a small proportion the metastasis was radically attacked and that the favorable results were obtained in the more recent instances, when electro-surgery had made its contribution toward clean and complete enucleation, shows that greater expectations for the future cannot be abandoned.

There are naturally certain criteria which are not to be disregarded in deciding an active surgical course. The most important of these is the question of multiplicity of metastases. Grant has well reviewed the literature concerning this possibility and there is evidently no doubt that the finding of a unique implant is rather the exception than the rule. There are, however, many examples of them on record, among which may be mentioned those of McKay,³ Lower and Watkins,⁴ and Schweitzer.⁵ Grant¹ reported ten cases of single tumor among twenty verified intracranial carcinomatous metastases but surmised that the number might not have been so high had more than three of the ten come to autopsy. Two of four cases of metastasis of the lung reported by Hall and Harding⁶ were

single. Globus and Selinsky,⁷ in a discussion of one of their cases, said, "Of interest also in this case is the singularity of a metastatic lesion, as these lesions usually are multiple. This feature permits the suggestion that operative intervention, even in suspected metastatic neoplasms, is not contraindicated for the mass, though metastatic, may be single and removable, on the other hand little is lost if the lesion proves to be multiple."

A careful clinical study should therefore be made to determine as accurately as possible the probability of there being but one lesion. Combined with this there should, of course, be a search for metastases elsewhere and a prognostication as to the course or recurrence of the primary focus. With these qualifications adequately evaluated the neoplasm in the brain need not be approached with too great trepidation, for it has characteristics which may modify its malignancy, as witness Cushing,⁸ who says: "It is an interesting thing that carcinoma metastatic to the brain is very apt to undergo degeneration and become cystic, evidently the brain is an unfavorable field" and Hassin⁹ in his statement that the tissues of the meninges behave rather passively toward carcinoma."

An important consideration has been reserved for the last. It may perhaps best be illustrated by the following case history.

CASE 4—Removal of carcinoma of the right breast nine years before admission. Development five years before admission of slight clumsiness of the hands and of slight difficulty in walking. Development nine months before admission of marked weakness of all extremities associated with pain and paresthesia. Operation with removal of an anteriorly placed meningioma wedged in the foramen magnum.

History.—Sarah G., a Jewish housewife, aged 50, was admitted to the hospital on Dec. 1, 1932, having been referred by Dr. George Hassin and Dr. William Boikan of Chicago. On Oct. 22, 1923 (nine years before this admission) she had been operated on by Dr. L. L. McArthur at St. Luke's Hospital for carcinoma of the right breast, a radical mastectomy having been performed.

The patient had been seen several months previously, when she gave a history of having been slightly clumsy with her hands and feet for four and one-half years. The symptoms were indefinite, however, had not interfered with the patient's doing her own work and were not superseded by anything concrete until five weeks before this time when she had suddenly become weak in all her extremities, uncomfortable paresthesia and shooting pains had developed in the extremities and even up toward the face. Neurologic examination revealed muscular weakness without atrophy, more marked on the left, active deep reflexes more active on the left, a bilateral tendency toward ankle clonus, more marked on the left, a positive Babinski sign on the left, equivocal on the right, diminished vibration sense throughout, most marked in the left leg, a slight impairment of the sense of position, apparently somewhat diminished common sensation throughout from the chin downward, but not markedly so, and no definite sensory level. Coughing caused shooting pains in the extremities but none in the back. There was no urinary or fecal incontinence, roentgenograms of the entire spine showed no pathologic changes and lumbar puncture revealed no abnormal serologic findings, though there was a complete block.

Although the patient's history up to five weeks before this examination was exceedingly indefinite, undoubtedly too little attention was paid to it. Perhaps the facts that during her life she had been subjected to a multiplicity of serious operations and that she was an extremely complaining patient served

to lead one to attach little importance to all but the most definite facts elicited from her. At any rate, it was felt that she was probably suffering from a recurrence of her old malignant condition, possibly in the form of a meningeal carcinomatosis.¹⁰ In the absence of a sensory level, she was given a course of roentgen treatments over the cervical and upper thoracic spine and dismissed with a poor prognosis.

On Dec 1, 1932, however, she entered the hospital with only a slight advance in her symptoms. There was still no sensory level, but the quadriplegia had become nearly complete, and, most important, she had developed what seemed like typical root pains in the distribution of the second and third cervical nerves, on the left. There was still a fluid block, though fluid findings were otherwise normal, and the patient still had bladder and rectal control.

Operation and Course—The chief complaint was pain in all the extremities, and it was for the possible surgical cure of this that the patient entered the hospital. Since she had a quadriplegia, without atrophy of the muscles of the arms or the hands, and what seemed like high cervical root pains, the laminae of the first four cervical vertebrae were removed in expectation of finding a metastatic lesion which could be partially removed, and of possibly doing a right-sided high cervical chordotomy, since the pain was most severe on the left. Instead of this, a large anteriorly placed meningioma was found, possibly the size of the two phalanges of the index finger. It was wedged in the foramen magnum, inside the dura, with possibly two thirds of its bulk in the cervical canal and the other one third in the posterior fossa. The tumor was removed piecemeal in its entirety with subsequent improvement of all symptoms.

Meagher and Eisenhardt² cited a similar case in which a suspected carcinomatous metastasis proved to be meningioma on roentgen examination and subsequent operative verification. In their case, however, the diagnosis could be made before operation. The case here detailed indicates even more poignantly that no person must be denied the opportunity to gamble on his chance merely because all the arrows seem to point in the direction of fatality.

Fig 3 (case 4)—Primary carcinoma of the breast

Perhaps the ability to report so few cases does not justify the drawing of definite conclusions. One cannot escape feeling however that they may help to modify a fatalistic concept for which there has been until but recently all too complete confirmation. The fifth anniversary of the first successful removal of a tumor of the brain has not yet been celebrated and one must not abandon any one class as hopeless without a struggle.

¹⁰ Lachsmeningitis carcinomatosa. A review of this condition is given in H2 in (this issue).

CONCLUSIONS

1 Three cases of carcinomatous metastasis to the brain are reported in which the periods of survival following intracranial operation are longer than in previously reported cases.

2 These periods of survival compare favorably with the results obtained from operations on relatively benign primary tumors of the brain.

3 One case of suspected carcinomatous metastasis to the cervical cord is reported, in which operation dis-

Fig 4 (case 4)—High cervical psammomatous meningioma

closed and made possible the removal of a meningioma, with recovery of the patient.

4 It is suggested that operation on suspected malignant metastases to the brain, provided the general condition of the patient warrants it and that the cerebral lesion is apparently single, be undertaken for the following reasons:

(a) It may be possible to extirpate the metastasis, with great relief to the patient and with prolongation of his life expectancy.

(b) If the lesion cannot be removed, at least palliative decompression can be performed for the relief of distress.

(c) Occasionally a gratifying surprise may be encountered in the form of a benign tumor, and no person should be refused this possibility.

30 North Michigan Avenue

ABSTRACT OF DISCUSSION

DR GEORGE W. HALL, Chicago: There are one or two things I would like to speak about from the standpoint of the neurologist. Sometimes the burden of proof is on the neurologist in making the diagnosis. Not many months ago an internist, myself and another neurologist were studying a case which we agreed was one of a brain tumor of benign origin. However autopsy showed that the patient had a primary carcinoma in the colon which had not been discovered during his illness. Dr Oldberg has brought out the fact that a benign tumor may be found instead of a metastatic tumor. I have seen more than one case in which a breast had been removed and a tumor of the brain developed in after years which demanded a great deal of thought as to the relation of one to the other.

DR WINCHELL MCK CRAIG, Rochester, Minn.: The question of carcinomatous metastases to the brain which Dr Oldberg has just emphasized is of extreme interest especially to those doing neurosurgery. It has been repeatedly demonstrated at the operating table that the pathologic diagnosis of an intracranial lesion cannot be made until tissue has been removed and

examined. In spite of the evidence in favor of a metastatic lesion, a totally different type of pathologic condition is often found, and even though the lesion proves to be metastatic, palliative relief may follow a decompression. Other lesions of the central nervous system, especially those of the spinal cord, in which there is evidence of metastatic malignancy, should be explored before definite pathologic diagnosis is made, because here again the lesion may be benign, and even if it proves to be malignant, the decompression may afford palliation. Several years ago I had under my care an elderly woman in whose case there had been made a diagnosis of carcinoma of the stomach with metastasis to the spine. This diagnosis had been made elsewhere, and when I examined her she was too sick for complete gastro-intestinal studies. Examination revealed a sensory level, subarachnoid block of the cerebrospinal fluid, and paralysis, and the most significant symptom was pain in the back and legs. At operation, an intrameningeal neurofibroma was found and removed, following which the patient regained her health and the gastro-intestinal symptoms disappeared. The diagnosis of malignant metastases to the central nervous system should be made only after pathologic verification.

DR. GEORGE B. HASSIN, Chicago. I wish to say a few words regarding the possible indications for operations for malignancy. I made a pathologic study of twenty-five cases of carcinoma of the brain that metastasized from various organs, and I don't recall one instance in which the carcinoma was presented by a single nodule. As a rule, the metastases are multiple, their amount probably depending on the duration of the carcinoma of the brain. If a person with carcinoma of the brain has the metastasis operated on at once, the surgeon may find only one focus, but in the course of time one nodule in the brain may give rise to a hundred or more nodules. Such cases are absolutely hopeless and an operation is useless. It may occur that even early cases diagnosed as carcinomatous involvement of the brain are inoperable, as it is not possible to say whether the patient has only a focus in the brain or also an additional carcinomatous meningitis. Such a condition is likewise absolutely hopeless. As to the carcinomas of the spinal cord, the metastases are not in the parenchyma. I have never heard of a carcinoma localizing in the spinal cord, but I saw instances of carcinoma invading the meninges and producing so-called meningitis carcinomatosa. The tumor is confined to the meninges sparing the cord or brain, or it invades the spinal ganglions and roots giving in early stages the picture of so-called neuralgia. When the real condition is diagnosed an operation is useless. Another type of metastasis occurs not in the meninges but in the epidural space. Carcinoma may metastasize in the epidural space in the form of a single nodule which can be removed. Operation should be done in such cases and for this reason I consider Dr. Oldberg's paper of great importance. Dr. Oldberg showed that even some cases of malignant involvement of the central nervous system may be benefited by surgical procedures provided the diagnosis is made early and a trained neurosurgeon is taking care of the case.

The Tiger Mosquito—The chief mosquito vector, or carrier, of yellow fever virus is generally called *Stegomyia fasciata* by British writers, and *Aedes aegypti* by Americans. It has other names, both Latin and English, and in tropical Asia and elsewhere is widely known as the Tiger Mosquito, from its black and white striped body and legs. Some writers describe it as essentially a town dweller, but I have often been bitten by it in villages, and even in the depths of high forest. Until quite recently, *S. fasciata* was believed to be the only vector of yellow fever, but research has added to the list a wide variety of mosquitoes, eight African and two American species, according to one authority, thirteen species, in a report published a few months later, "many kinds of common domestic mosquitoes," in a paper published in 1932. Until recently, too, it was believed that *S. fasciata* would fly but a few score yards from its birthplace but now it has been observed to fly long distances ranging from 400 to 1,000 meters. The distribution of *S. fasciata* is astonishingly wide, for it is found abundantly throughout the tropics everywhere—Still John. The Significance of Yellow Fever, *J. Roy. Army M. Corps* 61 268 (Oct.) 1933.

CHRONIC ULCERATIVE COLITIS

A DISEASE OF SYSTEMIC ORIGIN

LOUIS A. BUIE, MD

AND

J. ARNOLD BARGEN, MD

ROCHESTER, MINN.

This paper consists in part of a brief review of what has been learned about the bacteriology of chronic ulcerative colitis in the last ten years and will make the contribution of correlating the living and the post-mortem pathology. The first part deals with bacteriology, the second with the proctoscopic picture, and the third with the microscopic changes in tissue.

BACTERIOLOGY

We have learned to recognize chronic ulcerative colitis as a clinical entity and to recognize a micro-organism which we believe plays a part in causation of most cases. The results of the activities of this organism have been seen in the bowel of man, and the organism can be recognized by its appearance, its cultural characteristics and its biologic reactions. It has been dealt with in the laboratory for almost a decade.

Fig 1—The earliest microscopic lesion of chronic ulcerative colitis

We believe its connection with chronic ulcerative colitis has been established by fulfillment of those requirements accepted by bacteriologists generally.

Eight hundred and fifteen strains of this organism have been isolated from 1,100 patients with chronic ulcerative colitis, and approximately 500 of these strains have been injected into 1,000 rabbits. Lesions resembling those seen in the colon of man have followed intravenous injection of 65 per cent of the animals. The organism has been isolated from the blood stream of eight patients acutely ill with chronic ulcerative colitis.

This *diplostreptococcus* has been isolated from periapical dental abscesses of 148 patients with chronic ulcerative colitis and has been injected intravenously into animals. The typical lesions were found in the colons of 75 per cent of these animals. The organism has been found in tonsils of 100 patients with chronic

ulcerative colitis and has been injected into animals with results identical to those secured after injection of organisms from periapical dental abscesses

In 1932, of the total number of patients who underwent investigation in the Mayo Clinic because of diarrhea and who gave no evidence of chronic ulcerative colitis on proctoscopic or roentgenographic examination, the organism was found in only ten. Two of these ten patients returned at a later date, and early

Fig 2—Occlusion of the small blood vessels in the wall of the colon

signs of chronic ulcerative colitis were discovered on proctoscopic examination

During the same period, forty-eight other patients with diarrhea of unknown cause were referred by various clinicians working independently of one another, with specific requests that the diplococcus be searched for, and in no instance was the organism found

Method of Verification—Numerous methods of verification of the bacteriologic observations have been used consistently. The clinician, the proctologist and the bacteriologist have worked independently. The proctologist, without the knowledge of the bacteriologist, has at various times made cultures from normal bowels and from other sources than the bowel, in an attempt to recover the diplostreptococcus or to demonstrate that it could not be recovered. During one period, swabbings were taken from 100 normal bowels, cultures were made and the diplostreptococcus of chronic ulcerative colitis was isolated in only four instances. In ten cases the skin around the anal margins was swabbed and cultures were made, organisms were not found in any of the cultures

From 534 patients who did not have colonic disease cultures were taken from the throat and nose, and streptococci from these cultures were injected into rabbits.¹ Lesions were found in the colons of only 0.8 per cent of the animals that received injections. Cultures of staphylococci were obtained from the noses and throats of twenty patients with chronic ulcerative colitis and were injected into rabbits without producing colonic lesions

Specimens were removed proctoscopically from the colons of fifty-six patients with chronic ulcerative colitis and were cultured by all generally accepted methods for growing dysentery bacilli and in no instance were dysentery bacilli found. Specimens were removed proctoscopically from fifteen patients with

chronic ulcerative colitis, search was made for acid-fast bacilli, and material was injected into guinea-pigs without the production of tuberculosis in a single instance

Cook² obtained cultures of the diplostreptococcus from periapical abscesses of fifteen patients with chronic ulcerative colitis. He devitalized the teeth of fifteen dogs and filled the cavities with material obtained from these cultures. In seven of the fifteen dogs, chronic ulcerative colitis developed in between eight and twelve months after the inoculation. This was proved by proctoscopic and postmortem examinations. The same method was followed with fifteen patients who had gastric ulcer, iritis, arthritis, endocarditis, cholecystitis and myositis, in no instance did colonic lesions appear, although the animals were observed for two years

PROCTOSCOPIC CHARACTERISTICS

During the ten years previous to Jan 1, 1933, 1,348 different patients suffering with chronic ulcerative colitis were examined proctoscopically. Practically all these patients were subjected to proctoscopy more than once. During the same time patients with amebic dysentery, bacillary dysentery, tuberculous colitis, infestation with *Balantidium coli*, benign strictures, and other pathologic conditions of the colon, some indeterminate, were examined and the appearance was compared with that of those who had chronic ulcerative colitis. At first we were undecided as to whether we were encountering different diseases or various manifestations or stages of the same disease. However, we soon learned to distinguish chronic ulcerative colitis from other pathologic conditions of the colon and to distinguish various stages during its period of activity and quiescence. Its characteristics always gave us the impression that it was a disorder of systemic origin and in recent years this has become more apparent. Almost invariably, either in the history or in our search

Fig 3—Multiple thrombi of the larger blood vessels of the colonic wall

for foci, we found a clue as to the inception of the disease

The pathologic process consistently begins as a diffuse inflammatory reaction of the wall of the bowel. Usually the lower portion of the colon is first affected. This is a characteristic of the first stage of the active period. The second stage begins with the appearance of edema throughout the involved area. Soon, as the

third stage, miliary abscesses present themselves under the mucous membrane, and with rupture of these abscesses the fourth stage manifests itself by miliary ulcers. The period of quiescence is one of gradual recession, and with it the active pathologic process subsides. The inflammatory changes disappear either partly or entirely, the ulcers heal, and characteristic pocklike scars remain.

Fig 4—A small blood vessel packed with erythrocytes

MICROSCOPIC CHARACTERISTICS

Humphrey, working as a fellow in the Section on Pathologic Anatomy of the Mayo Clinic, first called attention to certain microscopic changes in the wall of the bowel in cases of chronic ulcerative colitis. He made a critical study of the pathologic changes in a case of chronic ulcerative colitis, and he noted particularly emboli and infarcts in the wall of the colon, with dissolution of the mucosa immediately adjacent.

Following this observation, the colons of fifty patients who died of chronic ulcerative colitis were studied. In eight of these fifty cases, changes were seen in various parts of the colon, illustrating the four stages observed at proctoscopy. These patients died of an acutely progressing, fulminating disease, or of perforation and peritonitis.

It is readily understood that not all patients who die of chronic ulcerative colitis, and who come to necropsy, exhibit the pathologic changes in the colon which, at proctoscopic examination, can be recognized as stages in the development of the disease. For instance, proctoscopic examination has been made of patients in the second and third stages of the disease, and a week later, in spite of treatment, the mucosa has been so nearly destroyed that no characteristics of the disease remained. The mucosa had seemingly been torn to shreds. On the other hand, in some cases of the fulminating type of the disease the characteristic ulcers could not be recognized, yet, from the clinical standpoint, the diagnosis of advanced chronic ulcerative

colitis was made, and when proctoscopy was performed, after a period of treatment, the characteristic scars were seen in the healed mucosa.

The earliest microscopic changes recognizable in the wall of the colon are small lesions associated with edema and hemorrhage. These are often of roughly pyramidal shape (fig 1). The capillaries in this region are dilated and packed with erythrocytes. Some of the erythrocytes seem to have spread throughout the adjacent tissue, giving the appearance of a red infarct. At the bases of these regions, deep in the mucosa and submucosa, capillary vessels are occluded by hyaline masses (fig 2). Tracing this further, it is found that the capillary originates from some occluded vessel deeper in the tissue, and finally distinct branches of blood vessels can be made out, which are filled with homogeneous thrombi (fig 3). In some regions the hyaline mass does not occlude the entire lumen and the spaces existing fill with erythrocytes, suggesting the canalization of a thrombus (fig 4). Because of the integrity and preservation of the limiting membrane of the surface of the mucosa, the impression is that the condition is of hematogenic origin and that it is not due to some agent originally present in the lumen of the bowel but which has disappeared.

The relation of these hemorrhagic lesions to the occluded vessels is striking, for disseminated among the myriads of such lesions there are places where the tiny blood vessels are not blocked and where there is no

Fig 5—Marked swelling of the wall of the colon in and near the mucous membrane

evidence of any pathologic change in the mucosa that apparently is nurtured by that particular vessel. The analogy between this and the early proctoscopic picture is at once apparent (fig 1).

The edema so characteristic of the second stage of the sigmoidoscopic picture is only rarely seen, because the patient does not come to the proctologist until after that stage has subsided. It is perhaps transient and not readily maintained in fixed tissues. However, it has

en seen and is depicted in figure 5. One can readily conceive of it as a rapidly progressive change. In the third stage, innumerable diplostreptococci are served in the wall of the colon. In some cases they are isolated from the blood stream, and it is readily understood how the infected infarcts result in the min-

Fig 6—Innumerable diplococci deep in the submucosa of the colon

Fig 7—An early mucosal and submucosal abscess with normal mucosal membrane at the edge of the field

ute abscesses (fig 6). In this stage then there appear roughly pyramidal regions of necrosis surrounded by hemorrhagic zones. In the necrotic center lie many polymorphonuclear cells in a mass of disintegrating tissue, and the limiting membrane is covered with exu-

date (fig 7). Close examination, however, reveals relatively normal mucosa at each side of this abscess. It should be noted here that these tiny abscesses have no relation to the lymphoid follicles, and intact follicles are found in spaces between these lesions of necrosis. No lymphoid tissue is seen in the immediate region of the abscesses or ulcers. These minute, necrotic areas, in many places are so confluent that large sections of colon are involved (fig 8). However, in many places the stages are clearly discernible and can be traced readily.

The formation of abscesses has just been described, and since nothing retains the minute abscesses except the thin inner membrane, the slightest trauma will uncover a tiny bleeding or purulent point. A microscopic section shows how very close to the lumen of the bowel these abscesses lie, and so it can easily be understood why mere touch of the membrane will result in ulcer.

The histologic appearance of the remaining layers of the colonic wall is dependent on the acuteness of the process at any given point. The thickness of the wall

Fig 8—A large section of necrotic colonic wall

noted grossly is very striking microscopically and through it there may be diffuse infiltration of lymphocytes and plasma cells, while in the regions immediately adjacent to this acute process polymorphonuclear cells are more apparent. Among the more acute processes there also appear evidences of healing. Sometimes the borders of ulcers are deeply undermined and there is little leukocytic reaction. Regenerating mucosal cells may be seen in more advanced cases of healing and this is probably the basis of the pocklike scar which so constantly is seen after healing occurs.

SUMMARY

After nearly ten years the part played by bacteria in the etiology of chronic ulcerative colitis apparently has been established. In this paper the correlation between the proctoscopic picture and the microscopic changes in tissue is pointed out.

ABSTRACT OF DISCUSSION

DR HORACE W. SOYER, St. Louis: The proctoscopic picture of ulcerative colitis is absolutely typical. I have verified the description of the lesions as presented by Drs. Buie and Bargon many times. The early stage of general edema of the mucosa is followed by the formation of the military abscesses and is succeeded rapidly by the military ulcers, finally culminat-

ing in the pocklike scars. I see another later stage frequently viz., a thickening of the membrane in patches with the formation of polyps with broad bases. This stage however may be considered a complication of ulcerative colitis rather than a definite stage of the disease. Amebic dysentery presents a characteristic picture. Lynch said it looked like smallpox of the mucosa. A smear readily discloses the presence of amebae. Tuberculous ulcers are larger distinctly characteristic ulcers with normal mucosa separating them. I have long advocated local treatment of the rectal lesions in ulcerative colitis. Many patients who are clinically well carry these lesions. The Birger diplococcus appears to burrow in the submucosa a fact that explains the chronicity and the frequent exacerbations observed in this disease. Patients with the acute fulminating form usually succumb, but a few get well. Birger's serum is indicated in cases of this character. Birger's serum has given good results in many subacute and chronic cases. Ileostomy should never be undertaken in the acute stage but should be reserved for the patient who survives and whose colon is irremediably crippled. I am glad to hear Dr. Lahey say that he removes the ileum from the cecum in performing this operation. I have seen fatal involvement of the ileum in patients in whom a simple ileostomy without detaching it from the cecum had been performed.

DR BENJAMIN JABLON, New York. Possibly my experience in a case observed over a period of eleven years may shed some light on the difference of opinion that has been voiced here. The patient came under observation in 1922 with a history of a chronic ulcerative colitis lasting over seven years, with hemorrhage, dysentery and ten or fifteen bowel movements a day. He was observed for three months but nothing could be done to control the condition or to establish the etiology. Multiple bacteriologic examinations were negative. The flora isolated never seemed to show any definite relationship or identity as far as the disease present was concerned. Three months after observation I decided to take advantage of some of the experience I had had during the war. By repeated cultures of material obtained on proctoscopic examination on enrichment medium which was designated as liver peptone medium and by subculturing every twenty-four hours in this medium from twenty-four to thirty-six hours a non-hemolytic diplostreptococcus was obtained which when administered in vaccine form controlled all the symptoms. The patient was a boy aged 17 at the time and retarded in growth. His growth was similar to that of a boy of 10. There were no secondary skin reactions or hematic effusions in the joints of the wrist and though attempts were made to control the conditions with every known specific it was impossible to produce any effect. This vaccine of the organism was given him and the boy is perfectly well today. He had a number of relapses. Each time he had a relapse diplostreptococcus was isolated from the stool. Each time he recovered and improved the diplostreptococcus disappeared.

DR E. JAY CLEMONS, Los Angeles. When Dr. Buie first presented this subject I became interested especially in the first stage of the disease. I organized the service of the Los Angeles County General Hospital so that every suspicious case would be put in my service for proctoscopic examination. It took four years of very careful work to find the initial lesion of this disease. I wish to voice the sentiment of Dr. Edward G. Martin of Detroit that, provided the Mayo Clinic never accomplishes anything else the discovery of the etiology of chronic ulcerative colitis had made its efforts not in vain.

DR L. A. BUIE, Rochester, Minn. In the work I am about to comment on the clinician, the proctologist and the bacteriologist performed their tasks independently. In cultures made from 100 normal bowels diplococci were found in only four instances. The bacteriologists did not know the source of the cultures. Cultures were made from the nose and throat in 543 patients who did not have chronic ulcerative colitis. Streptococci isolated were injected into rabbits and lesions developed in only 0.8 per cent of the rabbits. Staphylococci obtained in cultures from the nose and throat in twenty patients with chronic ulcerative colitis and injected into rabbits produced no lesions in the colon. From 1200 patients 1816 strains of the organism which we believe to be of etiologic significance

were isolated and 500 strains were injected intravenously into 1000 rabbits. Characteristic colonic lesions developed in 65 per cent of the rabbits. The organism was isolated from the blood stream of eight patients. The organism was isolated from peripapular dental abscesses of 148 patients and colonic lesions appeared in 75 per cent of the animals given intravenous injections. The organism was isolated from the tonsils of 100 patients and typical lesions appeared low in the colon of 75 per cent of the rabbits into which the organisms were injected. From forty-eight patients with diarrhea no diplococci were isolated. Specimens were removed from fifty-six patients and were cultured for dysentery bacilli with negative results. Specimens were removed from fifteen patients and cultures made for bacilli of tuberculosis gave negative results. Cook took cultures from teeth of men with chronic ulcerative colitis injected the organisms thus obtained into the teeth of dogs and produced ulcerative colitis in seven out of fifteen cases. Similar experiments with patients having arthritis, endocarditis, cholecystitis, iritis or endocystitis all gave negative results as far as the production of chronic ulcerative colitis in animals was concerned. Ileostomy was formerly done with a proportion of deaths that was fairly high but in 1932 we had 110 cases of chronic ulcerative colitis and only one ileostomy. Patients are not now dying in as large proportions as before.

PRODUCTION OF ENDOMETRIAL GROWTH IN CASTRATED WOMEN

THE MINIMUM DOSAGE OF THEELIN THAT IS REQUIRED

AUGUST A. WERNER, M.D.
AND

W. D. COLLIER, PH.D., M.D.
ST. LOUIS

Apes and Old World monkeys menstruate in a cyclic manner just as normal sexually mature women do. Edgar Allen,¹ Hissaw, Corner Hartman Morrell and others using castrated monkeys were able to produce endometrial growth followed by uterine bleeding after cessation of injections of theelin.

It was desirable to know what effect theelin would have on castrated women.

In a previous article we² described the effect of theelin injections on castrated young women whose uteri were intact. Endometrial hyperplasia was produced, as shown by histologic examination of tissue obtained by curettage before, during and at the end of the experiment. Bleeding from the uterus occurred both during treatment and within three to five days following cessation of injections. Activity in the breasts was characterized by a sensation of fullness, actual enlargement, tingling in the gland tissue and erection of the nipples. The subjective symptoms that follow castration disappeared and libido was increased in four of five patients. Large dosages of theelin were used.

From the Departments of Internal Medicine and Pathology, St. Louis University School of Medicine.

Because of lack of space this article has been abbreviated in THE JOURNAL by the omission of the case reports. The complete article appears in the authors' reprints.

Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Eighty-Fourth Annual Session of the American Medical Association, Milwaukee, June 18, 1933.

With the accomplishment of these results by the use of theelin in castrated women the next question immediately to present itself was What is the least number of rat units² that will duplicate the results obtained in the first experiment?

THE PATIENTS USED

With this idea in view, a second experiment was started, Dec 4, 1932, in which eight white castrated women whose uteri were intact cooperated. Their ages ranged from 22 to 36. Patients 3, 5 and 7 had been used in the previous experiment, but seven and one-half months had elapsed since treatment, and in each instance one of these patients was paired with another who had not received treatment before.

Amenorrhea was complete in all these patients since castration except for the postoperative menstruation that usually follows complete castration within two to five days. Five of these women had postoperative menstruation beginning within one to three days and lasting from three to seven days. Two of the patients

oughly for syphilis for about two years in municipal and university clinics just previous to receiving the theelin treatment.

EXPERIMENTAL PROCEDURE

Four curettements were done on each patient, a total of thirty-two in all. The first curettage was done just before the first injection of theelin was given and then at the end of each twenty-eight day period for three months. The cervixes in the new patients, 1, 2, 4, 6 and 8, were pale pink and firm and the cervical canals contracted. The cervixes of patients 3, 5 and 7, who were used in the previous experiment, had not reverted to the degree of atrophy which they showed originally. The cervix of patient 3 was moderately soft and full, the cervix of patient 5 was pale and contracted (it was this patient who needed a general anesthetic before dilation could be done in the first experiment). The cervix of patient 7 was not as atrophic as at the beginning of the first experiment, but the canal, although moderately contracted, dilated without much difficulty.

TABLE 1—Observations in Eight Castrated Women Before Theelin Treatment

Patient	Age Years	Age at Castration Years	Time Elapsed Since Castration	Bleeding Immediately Following Castration	Amenorrhea Since Castration	Decreased or Absent Vaginal Mucous Discharge Since Operation	Atrophic Endo- metrium Before Injections	Atrophy of Breasts	Subjective Symptoms of Castration	Decreased Libido
1	27	26	4 mos	Three days after operation for 3 days	Yes	Yes	Yes* moderate atrophy	Yes	Yes 18	Yes

* Details in report

menstruated within a week before and one on the day of the ovariectomy, and they did not bleed after operation as did the others.

This postoperative menstruation is mentioned here because, in some instances at least, it is comparable to the bleeding that occurred in the theelin-injected women used in this and the first experiment following the cessation of injections. Endometrial stimulation and growth of varying degree had occurred and the removal of the ovaries withdrew that-needed-something which our experiments seem to indicate may be theelin.

All patients had atrophy of the breasts and had markedly decreased or absent vaginal mucous discharge depending on the time that had elapsed since castration. All complained of the symptoms that accompany castration.

The physical examination of each patient did not reveal any abnormality. All laboratory tests were normal except the Kahn test of patient 2 which was 4 plus. This patient had been treated consistently and thor-

INJECTIONS OF THEELIN

Theelin was the estrogenic substance used in all patients.⁴ As in the previous experiment, all injections were made into the upper gluteal region about 3 inches below the iliac crest and about 1 inch deep, on alternate sides each time.

Following the initial curettement patient 1 was given 4 cc of theelin or 200 rat units daily. It was the intention to give patients 1 and 2 who had not been used before the same dosage as was used in the original experiment to act as a control. Patient 1 was rather apprehensive and sensitive for the first six weeks of the experiment so it was decided not to increase her dosage of theelin but to continue her on 4 cc daily for the ninety-one day period. As the treatment progressed this patient became very calm and cooperative and was no further cause for worry. Patient 2 was given 4 cc or 200 rat units for twenty-eight days, 6 cc or 300 rat units the second twenty-eight day period and 8 cc, or 400 rat units the last thirty-five days.

¹ The Davis Rabbit modification of the Allen Davis rat unit in Green's laboratory as applied by Parke Davis & Co. was used in the experiment.

⁴ Parke Davis & Co. supplied the theelin used in this work.

Patients 3 and 4 were given 4 cc., or 200 rat units, every other day. Patients 5 and 6 received 2 cc., or 100 rat units, daily, and patients 7 and 8 were given 2 cc., or 100 rat units, every other day. All patients were treated for a period of thirteen weeks, or ninety-one days.

EFFECT OF THEELIN ON THE BREASTS

All patients experienced activity in the breasts, characterized by a sensation of fullness and actual enlargement, tingling in the gland tree, erection of the nipples, increased pigmentation of the nipple area in three and aching and soreness of the breasts, especially when uterine bleeding occurred or at other times when they had symptoms and signs, such as they described as "a feeling that they would menstruate."

This was first noticed in patient 1 on the twenty-sixth day, patient 2 on the fourth day, patient 3 on the sixteenth day (in the previous experiment on the tenth day), patients 4 and 5 on the seventh day (in the previous experiment patient 5 noticed this on the fourth day), patient 6 on the tenth day, patient 7 on the twenty-fifth day (in the previous experiment on the seventh day), and patient 8 on the sixth day. These breast changes were constant and increasingly prominent throughout treatment after their first appearance.

EFFECT OF THEELIN ON THE UTERUS

Patients 1, 2, 6 and 8 had marked atrophy of the cervix and uterus, as evidenced by the size and pale pink color of the cervix. The cervix of patient 4, although castrated only three months, was about of normal size, but pale and hard, and the canal was tightly contracted. Patients 3, 5 and 7, who were used in the first experiment and who at that time had markedly atrophic cervixes, did not have a reversion to the previous degree of atrophy, although seven and a

half months had elapsed since the last treatment. Their cervixes were pale, having lost the deep purplish-red hue that they had at the end of experiment 1. The cervix in each was about normal in size, moderately soft and dilated without difficulty. The mucous flow was greatly decreased or absent in all at the beginning of this experiment.

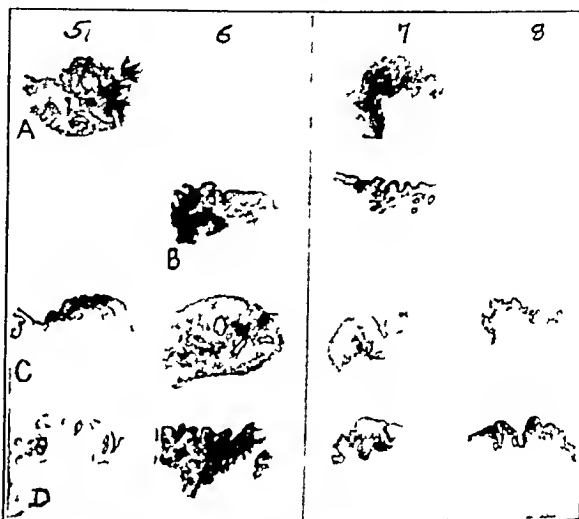

Fig. 2—Endometrium of patients 5, 6, 7 and 8. A before treatment, B after twenty-eight days of theelin administration, C after fifty-six days of treatment, D at the end of eighty-four days.

Fig. 1—Endometrium of patients 1, 2, 3 and 4. A before treatment, B after twenty-eight days of theelin administration, C after fifty-six days of treatment, D at the end of eighty-four days.

half months had elapsed since the last treatment. Their cervixes were pale, having lost the deep purplish-red hue that they had at the end of experiment 1. The cervix in each was about normal in size, moderately soft and dilated without difficulty. The mucous flow was greatly decreased or absent in all at the beginning of this experiment.

metriums which developed greatly on treatment, did not have a reversion to the previous state of atrophy at the beginning of the second experiment. Patient 4, who was also used in experiment 1, showed marked atrophy of the endometrium at the beginning of both experiments.

Uterine activity characterized by intermittent cramps, pelvic fullness, a bearing-down sensation and increased mucous flow was first noticed in patient 1 on the fifth day, patients 2 and 3 on the tenth day, patient 4 on the seventh day, patient 5 on the ninth day, patient 6 on the eighth day, patient 7 on the thirteenth day, and patient 8 on the sixth day. Congestion of the cervix, characterized by a purplish-red enlargement and increased vascularity, was noted in all at the end of the twenty-eighth day, at which time the first curettage following the onset of treatment was done. These objective cervical changes occurred earlier than at twenty-eight days as evidenced by the earlier uterine activity as given, but for obvious reasons they were not checked.

Uterine bleeding occurred in patients 1, 3, 4, 6 and 7 and 8 while on treatment and in patient 8 after cessation of treatment. There were fifteen periods of uterine bleeding in six of these patients. Except in four instances, all bleeding periods were accompanied by the symptoms that usually accompany menstruation in most women. These exceptions were in patient 1, who bled on the eighty-ninth day, and in patients 6 and 7 who were on small doses of theelin and who did have the subjective symptoms of menstruation with later bleeding. Patient 1 had uterine bleeding once while on treatment. This occurred the sixth day after the onset of treatment. This was moderately heavy and lasted one day. There was marked endometrial growth in this patient as a result of treatment.

Patient 2 did not bleed on treatment but had marked endometrial hyperplasia and a feeling that she would menstruate several times

Patient 3 had uterine bleeding four times while on treatment (This patient bled four times during the first experiment, which lasted ninety-three days, making a total of eight experimental bleedings during the two series of treatment) The first bleeding began seventeen days after the preliminary curettage and onset of treatment It was moderately heavy in amount and lasted one day The second bleeding began on the thirty-third day, five days following a curettage It was moderate in amount and lasted one day The third bleeding began on the seventy-sixth day, which was twenty days after the last curettage It was moderately heavy in amount and lasted one day The fourth bleeding began on the eighty-ninth day, five days following the last curettage, was moderate in amount and lasted one day All these periods of uterine bleeding were accompanied by the usual pelvic and breast signs and symptoms of normal menstruation and the patient stated that "she felt as she formerly did during menstruation before castration" Moderate endometrial growth was produced by treatment

Patient 4 had uterine bleeding on the eighty-ninth day of treatment, five days following the last curettage It lasted one day and was rather light in amount A cotton-tipped applicator introduced into the cervical canal was soiled with blood She did not have the feeling that she was menstruating This patient had been castrated three months and retained quite a bit of endometrial growth The first curettage apparently removed this and she later developed marked typical theelin hyperplasia

Patient 5 did not bleed while on treatment or afterward, but she frequently felt as though she would menstruate (This patient was treated in the original experiment as patient 4 and at that time bled once while on treatment and afterward) She had quite a bit of residual endometrium from the first experiment which was removed by the first curettage after which she developed endometrial growth commensurate with the amount of theelin given

Patient 6 had uterine bleeding three times while on treatment The first bleeding began on the ninth day following the first curettage and onset of treatment It was rather light in amount and lasted one day and a cotton-tipped applicator showed that it was coming from the uterus This bleeding was not accompanied by the sensation of menstruation The second bleeding began on the twenty-fifth day and twenty-five days following a curettage was light in amount lasted one day and was accompanied by the feeling of menstruation The third bleeding began on the eighty-ninth day was light in amount continued one day and was accompanied by the usual symptoms There was no bleeding after cessation of the injections She developed marked endometrial growth on treatment

Patient 7 had uterine bleeding three times while on treatment The first bleeding occurred on the fifty-ninth day and the second on the sixty-third day and both were scant and not accompanied by the subjective symptoms of menstruation The third uterine bleeding occurred on the eighty-ninth day the flow was free and bright soiled two napkins and lasted one day Speculum examination revealed this as coming from the uterus This bleeding was accompanied by the subjective symptoms of menstruation and the breasts were full and tense Moderate endometrial growth occurred

on treatment (This patient had been treated in the original experiment as patient 5 At that time she bled twice while on treatment and after cessation of injections)

Patient 8 bled cyclically four times while on treatment The first uterine bleeding occurred on the sixth, seventh and eighth days, the second on the thirty-third, thirty-fourth and thirty-fifth days, the third on the fifty-eighth, fifty-ninth and sixtieth days, and the fourth lasted nine days, from the eighty-seventh to the ninety-fifth day inclusive This last period of bleeding began five days before the end of the treatment and continued for four days thereafter All periods of bleeding were normal in amount and were accompanied by the usual subjective breast, pelvic and general symptoms that usually accompany normal menstruation Moderate endometrial growth occurred on treatment

RELIEF OF SUBJECTIVE SYMPTOMS

All these patients had most of the subjective symptoms that accompany castration Relief from these symptoms was had by patient 1 by the twelfth day, patient 7 by the ninth day, and patient 8 by the twenty-second day, patient 4 by the thirteenth day patient 5 by the fifteenth day, patient 6 by the fourteenth day patient 7 by the ninth day, and patient 8 by the twenty-first day

EFFECT OF THEELIN ON LIBIDO

Patient 1 stated that she had increased libido after the eighth day, patient 2 at the fourteenth day, patients 3 4 and 6 at the twenty-third day, patient 5 at the ninth day, and patient 8 after the seventh day This impulse became more compelling in all patients as treatment progressed except in patient 7, who was also treated in the original experiment as patient 5 She states that "libido was lost following the ovariectomy and had not been benefited by theelin treatment during either experiment"

IRRITATION FROM INJECTIONS OF THEELIN

Patient 1 was very apprehensive and quite nervous subjectively at the beginning of treatment and complained that the injection of 4 cc of theelin was very painful both during and for half an hour to several hours afterward There were also times when the patient said that she "did not feel some of the injections, depending on location given" There was a rapid response to treatment in this patient, and after the first six weeks she did not complain except for a burning sensation, at times, just after the injections All patients, at some time, stated that there was a burning sensation at the injection area for five to ten minutes following the injections, especially on the larger doses All patients were free from induration at the injection areas at all times

HISTOLOGIC REPORT

Scrapings removed at a preliminary curettage done on each patient at the beginning of the experiment furnished shreds of tissue sufficient for microscopic study in only four of the eight patients used in this study Two of these four were used in a previous experiment in which theelin was administered, and two were from new patients who had never received theelin The latter two had been castrated less than six months previously and this has been found to be insufficient time for advanced estrate atrophy to have occurred The two patients used in the previous experiment mentioned showed endometrium quite unlike the normal The abnormalities were those characteristic of theelin

administration This, together with later evidence, shows that a certain amount of endometrial growth must have occurred after the last curettement of the first experiment and that at least some of it must have persisted for the intervening period of seven months. The third patient in this experiment, who was also used in the previous experiment, did not present any material for study at the end of the seven months interval between the two experiments. The endometrium of this patient did not respond as markedly as that of the other patients of the first experiment, which may account for the more rapid disappearance of the theelin effect on the endometrium in this patient. Patients 2, 6 and 8 of this experiment furnished no endometrial tissue on the preliminary curettage. They had all been castrated over a year and had received no theelin therapy.

A study of the curettements taken a month after the beginning of theelin therapy showed a slight amount

of treatment. The increase is also roughly proportional to the amount of theelin administered. Patient 8, who received the smallest dose, presented material for microscopic study for the first time. So we can say that all eight patients responded to their respective doses of theelin varying from relatively massive doses to 100 rat units every other day. There is a definite tendency for the glands to be longer and more complex. Patients receiving the larger dosage show very atypical, complex glands with intrapapillary processes and irregularity in the size of the lumens. There is also an appreciable congestion of vessels in the stroma.

After the third month of theelin administration, the uterine scrapings showed relatively still greater growth in all patients. This might be questioned in cases 4, 6 and 7 if one were to compare the actual thickness of the endometrium as recorded in the pictures of the patients at the end of the second month with the picture record at the end of the third month. The apparent

of endometrium from all patients except patients 1, 5 and 8. The endometrium resembled a normal regenerating endometrium with no appreciable abnormalities. The presence or absence of the kind of endometrium found on preliminary curettage did not influence the amount or kind of growth induced by theelin administration during the month. Apparently, the endometrium found on preliminary curettage represents a persistence of endometrium that has been induced by forces which are no longer active, in view of the following observations. The endometrium of patients 5 and 7 which showed characteristics of theelin stimulation on preliminary curettage, failed to exhibit these characteristics in the response to theelin readministration to these patients. They did, however, later reexhibit these characteristics after continuation of therapy without changing the dosage. Their reactions, as well as those with incomplete castrate atrophy at the beginning of the experiment, paralleled those with more advanced castrate atrophy.

There is a definite increase in the thickness of the endometrium after the second month of theelin administration over that found at the end of the first month

thickness must be corrected in these three cases at the end of the second month. These pictures are of tangential cuts of endometrium and appear thicker than would be the case if they had been cut at right angles to the surface plane. More suitable pictures could not be obtained. It is obvious, however, from the pictures that there is greater complexity of glands, greater density of stroma and more hyperchromatic cells in the sections made from the curettements at the end of the third month.

So far, the evidence has been presented to show that with a given dose of theelin the degree of growth of the endometrium is directly proportional to the duration of administration under the conditions of our experiment. There is another possible variable, the size of the dose. The degree of growth of the endometrium is also roughly proportional to the size of the dose of theelin administered if administered for the same period of time. There must be limitations of both these factors, but these limitations lie beyond the conditions of our experiment.

The greatest degree of growth was found in patient 2, who received by far the largest quantity of theelin

This patient received the same amount of theelin in the same period of time as was carried out on five patients in our previous experiment, and the endometrial reaction is the same in this patient as the reactions found in the four patients of our previous experiment.

Patient 1 received the same dose daily throughout the experiment. This dose was the same as that given patient 2 during the first month, two-thirds that given patient 2 during the second month, and one-half that given patient 2 during the third month. The degree of endometrial hyperplasia was much less than that of patient 2, just as the total quantity of theelin administered to patient 1 was much less than that administered to patient 2.

Patients 3 and 4 showed much less endometrial growth than patient 1, although the dose administered and the duration of administration were the same. The variation that explains the difference is that patient 1 received this size dose daily, while patients 3 and 4 received this size dose only on alternate days.

Patients 5 and 6 showed approximately the same degree of growth as was found in patients 3 and 4. Patients 5 and 6 received half the size dose every day that patients 3 and 4 received on alternate days, essentially identical dosage.

Patients 7 and 8, receiving the same size dosage of theelin as patients 5 and 6, but only half as often, show considerably less amount of endometrial growth than patients 5 and 6. It is interesting that the total quantity of 2,800 rat units was administered during the fifty-six days before we obtained any evidence of endometrial growth and that in our previous experiment we found that we had given 2,800 rat units in two weeks to obtain the same results.

The atypical gland formation so characteristic of our theelin administration experiments in which large doses were used was found to occur and thereafter persist in five of our eight cases. It is usually found to occur earlier and eventually in more marked degree in patients receiving the larger size dosages. The intensity of congestion is also roughly proportional to the dose and period of administration of theelin.

There seems to be no essential difference in the degree or kind of reaction between the patients receiving theelin for the first time and those who received intensive theelin therapy previously. The new patients 4 and 6 seemed to react more markedly than their comparable mates 3 and 5, who received intensive theelin therapy seven months previously, but new patient 8 reacted much less strongly than her mate, patient 7, who had previously had theelin therapy.

COMMENT AND CONCLUSIONS

It was noted at the beginning of this article that we had completed a previous experiment in which large doses of theelin were given to five castrated women, four of whom had their uteri intact, with the production of certain definite results.

The results obtained in the present experiment substantiate the results of the original work. It was found that massive dosage is not necessary to produce endometrial growth but that small repeated doses long continued produce growth which is roughly proportional to the amount and duration of the theelin injections. In the original experiment endometrial growth was produced by the fourteenth day, at which time 2,800 rat units of theelin had been injected. In this experiment reference to figure 1 will show that patient 3 first

developed endometrial growth at the end of twenty-eight days, as a result of having had 2,800 rat units of theelin administered. Patient 8 (fig. 2) first showed endometrial growth at the end of fifty-six days, at which time she had had a total of 2,800 rat units injected.

Such evidence as we have points to 2,800 rat units as the "minimum clinical dosage", from the point of view of rigorous scientific investigation, to be sure, such a dosage may not be the same as the effective minimum dosage. The clinical dosage must be large enough to allow for elimination of the drug and still enable the animal to retain enough to be effective in securing the physiologic result. With this reservation in mind, we feel that our paper has given evidence that 2,800 rat units, whether administered over long periods or over a shorter period, must be considered the minimum clinical dosage. Furthermore, we are aware of a number of problems that this statement creates. We have as yet no conclusive evidence on the relationship between the quantity administered and the quantity eliminated, or between the length of administration intervals and the quantity eliminated. On these points further work is definitely indicated, yet ignorance of such quantitative relationships need not necessarily and, on the basis of such evidence as we have here afforded, does not invalidate the remarkable correspondence with reference to the minimum clinical dosage that we have found in the larger number of our cases.

We might also here call attention to the fact that our experiments seem successfully to meet the question that has been often asked whether or not smaller doses might not produce the results actually obtained from the administration of theelin. We are judging the minimal dose by the development of a clearly recognizable and accepted criterion. Dosages, therefore, given previous to the development of this criterion, namely, the production of endometrial growth, must be considered clinically subminimal dosages.

Uterine bleeding, which occurred frequently, did not bear a definite relation to the degree of endometrial growth. Patients 7 and 8, who received 100 rat units of theelin every other day, showed endometrial growth and had uterine bleeding, in fact, patient 8 bled cyclically on four occasions in a normal manner. The breasts and genital tracts of all patients showed enlargement and greatly increased activity. Relief from the subjective symptoms that follow castration was had in all patients, and libido was markedly increased in nine of ten patients who were treated in the two experiments.

ABSTRACT OF DISCUSSION

DR. EMIL NOVAK, Baltimore. The chief value of this contribution is in the demonstration of a method of approach which while not altogether new has had only limited application. The castrated woman offers a very good means for studying some of the problems of reproductive physiology. The method has been used as Dr. Werner and Dr. Collier know, particularly by Clauberg and Kaufmann in Germany. It has been possible not only to produce hyperplasia by very large doses of theelin but to convert such a hyperplastic mucosa into a pregravid one. It has also been possible to reproduce in the castrated woman a genuine menstruation both clinically and histologically by the administration of enormous doses of theelin (310,000 mouse units) followed by large doses of progestin (corpus luteum factor) totaling 90 rabbit units. The bits of tissue of which the authors show pictures are so tiny that it is difficult to draw conclusions from them. They cer-

tantly do not show hyperplasia in the sense in which gynecologic pathologists use the term. But there is no doubt, on the basis of considerable experimental evidence, that such a condition can be reproduced. I believe that the authors' results would be more clearly defined if they did not interrupt their study so frequently by the disturbing factor of curettage. Such studies as these add additional evidence in support of the broad principle that functional uterine bleeding, including that of normal menstruation, is due to a withdrawal or abrupt diminution in the level of the folliculin content of the blood. If a maturing follicle or a maturing corpus luteum is excised, bleeding results after an interval of varying length. If a castrated animal is given theelin daily for seven or eight days, bleeding results, but not until some days after the withdrawal of the theelin. I have elsewhere summarized the evidence for this rather fundamental principle in the causation of uterine bleeding and have discussed also the equally important role played by the reciprocal effects of the ovary and the anterior hypophysis. The authors mentioned that in some cases evidences of hypersecretion were seen in the endometrium after the injection of theelin. This is contrary to accepted ideas, if they mean a real secretory activity of the epithelium such as is found in the pregravid or secretory phase of the cycle. Indeed one of the criteria in the microscopic diagnosis of hyperplasia of the endometrium is the absence of any secretory activity.

DR J. P. PRATT, Detroit. Dr Werner and Dr Collier have opened the possibility of many problems for discussion. Among the most important of these is the demonstration of concrete anatomic and physiologic evidence of reaction to theelin by the human ovary. This contribution is especially welcome in view of the fact that animal experimentation with hormones has advanced far beyond the clinical application and that results of animal reactions have been applied by analogy to clinical problems with frequent unsatisfactory consequences. Among animals, many striking variations appear in their reaction to hormones even in closely related species. This demonstration of reaction in the human subject therefore is extremely valuable. Separation of their objective from their subjective evidence is most important, for the latter is difficult to evaluate. For this reason, observation of a change in such symptoms as libido may be open to question. How much of the change was due to psychotherapy? Reports of attempts to substitute for ovarian deficiency are numerous, but the authors hold a unique position in reporting unquestionable evidence of reaction to ovarian hormone in a series of cases in which the ovaries were absent. Even in their series considerable individual variation in response to a given dosage was noted. This emphasizes the difficulty of estimating the amount of hormone needed to substitute for deficiency when the ovaries are present but are not functioning normally. There is no satisfactory means of measuring such a deficiency.

DR E. B. WOODS, Iowa City. I would like to ask Dr Werner and Dr Collier whether they are able to get a hyperplasia in the true sense of the word, as Dr Novak has brought out, showing mitotic figures, an enlargement of glands, and new growth of interstitial tissue. Dr Hisaw of the University of Wisconsin was able to obtain a true hyperplasia but without the tortuosity of the glands and the 'swiss cheese' appearance which he considers to be definitely the result of the corpus luteum hormone.

DR AUGUST A. WERNER, St. Louis. Dr Novak remarked that these women did not bleed following the cessation of injections and that it might be due to the fact that there were too many curettements. In the first series of five women one woman had a high cervical amputation and of course she could not bleed, but three of the patients bled following cessation of injections after twenty-six curettements had been done in the first experiment which ran three months. There were thirty-two curettements done in the present experiment. Why patient 2 who was on the same dosage as that used in the first experiment and who was used as a control did not bleed I cannot tell. Dr Pratt spoke about libido. I know as well as any one that libido is an intangible something, a subjective impulse but the patient's word has to be taken for it. If a patient says that she formerly had normal libido and potency and that it was lost as a result of castration or that she had

the subjective symptoms that accompany castration or the menopause, and if after treatment the woman says "Doctor, I feel better than I ever felt in my life," one has to accept it. In reply to Dr Woods the function of theelin is to produce the interval change or growth in the endometrium, and then the secretory phase is produced by corpus luteum. These women did not have any corpus luteum. Corpus luteum will not have any effect on the endometrium unless it has been primed by theelin or the follicular hormone.

USE OF DINITROPHENOL IN OBESITY AND RELATED CONDITIONS

A PROGRESS REPORT

M. L. TAINIER, M.D., A. B. STOCKTON, M.D.

AND

W. C. CUTTING, M.D.

SAN FRANCISCO

We have recently suggested that alpha-dinitrophenol (1-2-4) might have therapeutic value in conditions in which an increased metabolic rate would be beneficial. Study of its pharmacologic properties shows that it has the power to increase metabolism to very high levels without causing important damage to vital organs and functions. Serious harm is apparently only caused by the drug in large doses which produce too great metabolic stimulation, with resulting fever. In low, or therapeutic, doses, the metabolism may be increased 50 per cent or more over considerable periods of time without unpleasant symptoms or toxicity. Such an action is useful in treating obesity, since the increased metabolism results in loss of weight, just as it does with thyroid medication. This paper is in the nature of a progress report on results obtained to date of treating 113 consecutive cases of obesity observed in clinic and private practice.

No attempt was made to select the patients on the basis of special suitability for this treatment, and about one half of them were given dinitrophenol only after thyroid administration and dietary regimens had failed to achieve further reduction. Our report, therefore, indicates the kind of therapeutic results that may be obtained in the least promising cases of obesity. Much better results than ours might reasonably be expected with the more responsive types of obesity.²

The drug was used in the form of dinitrophenol itself or as its sodium salt. Capsules containing 100 mg of the sodium salt, or its equivalent of 75 mg of the acid, were used throughout. The two forms were therapeutically indistinguishable, as was to be expected. The usual routine was to start a patient with a dose of one or two capsules daily, given with meals, and after a week's interval to increase the medication as necessary until a weight loss of 2 or 3 pounds (0.9-1.4 Kg) weekly was produced. If patients were on a special diet at the beginning of dinitrophenol treatment, they were kept on this, otherwise they were advised to eat their normal diet without rigid restrictions. Although this undoubtedly diminished the amount of weight reduction obtained, it had the benefit of testing the drug under

2. The authors are indebted to the following physicians who by their cooperation made this report possible: Drs. H. Cabot, Brown, Everett, Carlson, D. A. Carson, H. H. Darling, C. H. Dent, Horace Gray, W. A. Johnson, D. H. Kaump, J. E. McGuinness, R. B. Penzotti, Frederick Proeschler, William Van Deventer and Leona Bayer Wolf.

adverse conditions. The patients returned for observation at intervals of from one to three weeks, at which times they were weighed and examined for general symptoms and for evidences of toxicity.

LOSS OF WEIGHT

The entire series of patients here considered were adults with an average initial weight of 188½ pounds (85.5 Kg). Only fifteen of 113 were males, so that the material consisted almost entirely of obese females. The average length of treatment for each patient up to the time of this report was forty days, but some have been treated as long as 125 days and others until they had lost all the weight desired. The average loss of weight per patient was 8½ pounds (4 Kg), which, with the average duration of treatment of forty days, would give a rate of loss of 1½ pounds (0.7 Kg) weekly. This average, of course, included the beginning period during which adequate dosage was being established and so does not represent the usual rate of loss under full treatment.

DOSAGE

When the data were grouped according to the dosage required for a reduction of from 2 to 3 pounds weekly, which was set up as our optimum it was found that the average daily dose of dinitrophenol required was 29 capsules per patient, or 1.5 capsules for 100 pounds of initial body weight. No general relationship could be demonstrated statistically between a given dose and the resultant weight loss, since, by our method of administration, the higher doses were given only to patients who resisted lower doses. Consequently, the higher dosage groups showed no consistently better losses of body weight than did other and more sensitive patients on lower doses.

In seven patients a dose of one capsule daily (from 0.5 to 0.75 capsule for each 100 pounds) was found sufficient to produce our standard rate of loss in body weight. At the other end of the scale were twelve patients who took five or six capsules daily (from 1.8 to 3.2 for each 100 pounds) to attain the same reduction. The fastest loss of body weight observed was in a 256 pound (116 Kg) patient who lost 13 pounds (6 Kg) in two weeks on three capsules daily. The largest absolute amount of the drug was taken by a woman of 236 pounds (107 Kg) who decided she was thin enough at the end of 125 days' treatment when she was reduced 49 pounds (22 Kg). In all she took a total of 540 capsules, or 54 Gm of sodium dinitrophenol or an average daily dose of 4.3 capsules with an average weekly loss of 2½ pounds (1.2 Kg) in body weight.

PRESENT STATUS OF PATIENTS

In the entire series of 113 cases seven were lost track of, so that our records on them are of no value. Nineteen others had their treatment terminated at varying intervals for reasons not associated with the drug or their medical treatment. Of the remaining patients, twenty-three have been dismissed with their treatment completed, fifty-two are still being treated, nine had the dinitrophenol therapy stopped because of unpleasant reactions, and three cases were given up as being uncomplicated failures at the drug. The last two groups included twelve patients or 10.6 per cent of the entire group in whom the use of the drug could be considered unsuccessful.

In the group in which reduction was completed there was produced an average loss of 13½ pounds (6.3 Kg)

in body weight in 51.8 days, or at the rate of 2½ pounds (1.1 Kg) weekly, on an average dosage of three capsules daily. Those still being treated have lost an average of 7½ pounds (3.5 Kg) in 34.7 days on the same average dose. In the three cases in which treatment was stopped because of lack of reduction two gained slightly in weight during two to three months of treatment and the third lost only 9 pounds (4 Kg) in eighty-one days. These were all treated in the beginning of our tests with the drug when we did not feel free to administer the doses that have since been used in such resistant cases. It is reasonably certain, therefore, that these three cases would have a better outcome if they were treated at present.

FAILURES

The true failures of the drug consist in the nine patients in whom it was discontinued because of unpleasant reactions. Of these nine patients one was stopped because of a cystitis, possibly caused by a concentration of the urine as the result of profuse sweating, two because of a temporary derangement of their sense of taste, one because of a temporary gastroenteritis which, however, may have been only a coincidence and five because of skin reactions that required stopping of the drug. These reactions were observed in patients getting no more than the average dose of the drug and so were the expression of increased individual sensitivity. These reactions are discussed in more detail in connection with the side actions caused by the drug.

SIDE ACTIONS

The predominant action of dinitrophenol is to stimulate metabolism and heat production, so that the outstanding symptoms from its use are increased warmth and perspiration.² These are experienced to some degree by practically all patients, the intensity being governed to some extent by the ease with which the patient can dissipate the excess heat produced by sweating and vasodilatation of the skin and partly also by the atmospheric temperature and humidity. About double the dosage reported in this paper is required to produce a detectable elevation of the body temperature as measured with an ordinary clinical thermometer. In twenty-seven, or 23.9 per cent of the patients perspiration or a sensation of warmth was sufficiently marked to cause complaint but in none was it so marked as to require stoppage of the drug. As a result of the increased warmth the patients wore less clothing and exposed themselves more to drafts. Colds or evidences of sinusitis were observed in ten or 8.9 per cent of the patients while on the drug but whether or not this is a real increase over the usual incidence of such disturbances we are not in a position to say. Four patients complained of shortness of breath on exertion while taking the drug.

Six of the patients or 5.3 per cent, complained of feeling tired and three others thought that their nervousness was increased. Four patients said they had attacks of dizziness. These were all psychoneurotic patients mainly at the menopause so we are not inclined to attach much significance to these particular complaints. Three had gastro-intestinal upsets of brief duration.

² Tainter, M. J. and Cutting, W. C. J. Pharmacol. & Exper. Therap. 48, 410 (Aug.) 1933. (1) to be published. Hall, A. F., Field, J., Sabers, M., Cutting, W. C. and Tainter, M. J. Am. J. Physiol. to be published. Cutting, W. C. and Tainter, M. J. Metabolism of Dinitrophenol. J. A. M. A. to be published.

Of a much more tangible nature, however, was an alteration in taste experienced by six patients. Three of these were in one family group, but the other three were entirely unrelated to any of these six patients. After several weeks of treatment with two or three capsules daily, these patients lost the power to discriminate between sweet and salt tastes. There was no disturbance of their other taste sensations or of other special senses. The drug was withdrawn from two of these but not from the other four patients, recovery was complete in all in from two to three weeks. We are not prepared at present to interpret the possible significance of this particular symptom.

The most important side action encountered was a skin rash, observed in eight patients, or 7 per cent of the entire series. This was manifested, usually after a one-day prodrome of mild itching, by a maculopapular or urticarial type of rash. The itching was rather intense, and with the urticaria there was considerable swelling. If the drug was withdrawn the reaction subsided in from two to five days. Treatment consisted of the usual soothing lotions and sedatives, as necessary. No sequelae have been observed. In three of the patients, dinitrophenol treatment was successfully resumed after the skin reaction subsided, without recurrence. This type of reaction is similar to the dermatitis medicamentosa of many agents but appears to occur somewhat more often with dinitrophenol in the dosage used than it does with some other common remedies. It seems to be the chief disadvantage in the use of this drug.

In all the otherwise normal obese patients there were no respiratory or circulatory symptoms, except possibly a shortness of breath in four patients. Seventeen of them, however, had systolic blood pressure over 140 before treatment was begun. In this group the average systolic pressure was 166 and diastolic 100. At the present time, the averages are 142 systolic and 86 diastolic. Their hypertension has definitely decreased during treatment. Nine of these patients are still under treatment, so that further change may occur. In patients with normal blood pressures, no important change in either systolic or diastolic pressure, or in pulse rate, has been demonstrable. Two of the hypertensive patients had albuminuria for some months prior to the dinitrophenol treatment. In both of these the albuminuria had disappeared by the end of the treatment. We have made many examinations of urines of patients on dinitrophenol treatment but have never observed the development of an albuminuria.

Three patients of the series were having attacks of angina pectoris. One had been having daily chest pain for one month, and another one had pain twice a week for over two years. No further attacks have been experienced by these patients since the first week on dinitrophenol, although they are eating and exercising more than previously.

Because of its relationship to trinitrophenol (picric acid) and other compounds, dinitrophenol might be suspected of damaging the liver. Indeed, under maximum dosage, some patients take on a slightly jaundiced appearance, especially of the sclera. It should be remembered that the drug itself is of the same color as bile pigments, appears in the urine and imparts to blood serum a color that would be read in the ordinary icteric index test as an abnormally high value. If to the serum is added a drop of 5 per cent solution of hydrochloric acid the dinitrophenol is decolorized without modifying the color of bile pigment and the true icteric index can

then be read. Using this test, we have not observed any evidence of liver damage, but further studies are being made.

COMMENT

These results show that dinitrophenol can be used therapeutically to reduce the weight of obese patients regardless of the etiology of the obesity, and even when low caloric diets, or thyroid administrations, are ineffective. The loss of weight takes place predominantly from the hips and abdomen, as shown by measurements; the other regions share in the loss but to a lesser degree. A sufficient amount of the drug can generally be taken without discomfort to cause a loss of from 2 to 3 pounds weekly over extended periods. Indeed some patients even experience a feeling of improved well being. We have no evidence that dinitrophenol shares the hormone actions of the thyroid, even though both agents do increase metabolism. We are publishing separately observations indicating that the actions of thyroid and of dinitrophenol on cholesterol metabolism and on tadpole metamorphosis are different. Therefore, it appears that when a definite lack of thyroid secretion exists, dinitrophenol cannot supply this deficiency but can only be a symptomatic remedy in reducing the excess body weight.

Aside from the skin reactions the chief danger from this drug is in the indiscriminate or careless overdosing that may result from its sale to the public. It has already been demonstrated that an overdose of sufficient size will cause a fatal pyrexia in man, just as it does in experimental animals.⁴ That an overdosage may be toxic does not constitute a sufficient reason for not using dinitrophenol any more than for any one of many potent drugs commonly employed by physicians, but it does indicate that the treatment must be directed by the physician. For maximal safety the initial dose of dinitrophenol should be small and increasing doses may be employed only as the clinical response seems to warrant.

CONCLUSIONS

1 Alpha dinitrophenol (1-2-4) has been used in treating 113 consecutive cases of obesity.

2 The treatment was not successful in only twelve of these cases in three because of inadequate loss of weight, probably due to insufficient dosage, and in the other nine because of undesirable reactions to the drug.

3 An average loss of weight of between 2 and 3 pounds weekly was produced by an average daily dose of 0.3 Gm (5 grams) of the sodium dinitrophenol, in capsules taken with meals.

4 The drug has been administered to individual patients by us continuously for as long as four months without demonstrable evidences of cumulative or toxic effects.

5 The hypertension and albuminuria associated with obesity have been improved by dinitrophenol in a limited number of patients responding with reductions of body weight.

6 The most important side action has been a skin rash, which occurred in 7 per cent of patients and which necessitated stoppage of treatment in 4.4 per cent of them. The next most important side action was a loss of taste for salt and sweet, observed in 5.3 per cent of the patients. Both of these side actions cleared up quickly without sequelae.

⁵ Cutting C. C. and Tainter M. L. Proc. Soc. Exper. Biol. & Med. to be published.

7 A suitable regimen of dinitrophenol medication for adults would appear to be an initial daily dose of 100 mg of the sodium salt orally, taken with meals, with an increase at weekly intervals until a dose is established that causes a loss of body weight of between 2 and 3 pounds weekly or too marked or unpleasant symptoms of warmth and sweating

PRESENT STATUS OF VARIOUS SPINAL ANESTHETICS AND THEIR CLINICAL USEFULNESS

FRANK W MARVIN, MD
BOSTON

The ideal anesthetic is still being sought and the day is not far distant when, in my opinion it will be found. Spinal anesthesia, as with all science, is constantly changing and fortunately progressing. In this progress the profession must have faith, and out of it will emerge a more exact knowledge as to the use of the various spinal anesthetics employed today. Records of anesthesia must be standardized, so that the immediate and remote effects of these drugs may be carefully studied. When this is accomplished, one should be able to develop positive opinions rather than impressions regarding the choice of the anesthetic. This choice must not only afford safety to the patient but also produce ideal conditions so that the surgeon may employ his technic of gentleness, accuracy and speed in the performance of the operation. The only contraindication in the use of spinal anesthesia, in properly selected cases, is ignorance or inexperience. New paths are rocky, however, and those who follow them must be prepared for the criticism accorded all pioneers.

As a result of its satisfactory employment in both the bad and the poor risk cases for operative procedures, spinal anesthesia became at first tolerated, later accepted, and now appreciated. The hazards of spinal anesthesia have been so largely overcome and its noxious effects on the circulation have been placed under so much better control that its use in surgery is fully justified. Hence, it behooves one to use it fre-

advise every one to employ his own technic in his own clinic. Not every new method that comes along should be adopted. If an anesthetist has good results he should continue with his technic, but on the other hand, he should not be contented to squat and ignore the newer and better preparations with the improved methods of application. Dr W Wayne Babcock has aptly stated that "as we progress we lay aside these aids of previous days with grateful reverence, not with apology or disdain. We shall not scorn what was done yesterday because we have something better today, any more than our interest in the past will cause us to continue the practice of the past."

Drugs formerly used in spinal anesthesia are now being replaced by newer and less toxic ones which give better and more satisfactory anesthesia. Nearly every drug employed as a local anesthetic has been injected into the subarachnoid space. Forty-nine years ago, cocaine was the first local anesthetic, introduced by Karl Koller, one year previous to the intraspinal anesthesia accidentally produced by Corning of New York. Twelve years later, Bier attempted to produce analgesia in the lower part of the body by blocking the nerve trunks of the cauda equina. The first successful operation in

TABLE 2—Comparative Fatal Intravenous Dose for Barbitals and Cats

Supercaine	9	2.0		0.5	2.1	5.0	3.5	14.2

America with spinal anesthesia was performed by Matas, in 1889. The high toxicity of cocaine precludes its use in spinal anesthesia. It is used, however, as a standard to gage the toxicity of the other drugs. Cocaine, having fallen into disuse, was supplanted by several drugs, of which I shall mention tropacocaine hydrochloride, stovaine, procaine hydrochloride and others.

Tropacocaine hydrochloride has been used quite extensively in the past. It has a toxicity about half that of cocaine, but its duration of action is much shorter. To be effective, it must be used in a fairly concentrated solution. Because of its high toxicity and rather uncertain analgesia, tropacocaine hydrochloride has been gradually discarded.

Stovaine, prepared by Fourncau in 1904 and brought into general use by Barker in 1906, has enjoyed great popularity, especially in France. It is powerful, and it produces marked muscular relaxation. There are, however, certain disadvantages in that it is more irritating to the connective tissues and nerve fibers. Headaches of rather severe intensity are noted frequently after its use. It deteriorates rapidly and must be kept in special containers.

Spinocaine (a brand of procaine hydrochloride with strychnine sulphate), introduced by Pitkin six years ago, gained a wave of popularity at first but of late it has been more or less replaced by procaine hydrochloride. The fact that it is of lighter specific gravity than the spinal fluid caused several accidents which could have been avoided had more care and precaution

TABLE 1—Number of Spinal Anesthetics During 1932

quently in the good operative risks. This change is gradually taking place, so much so, that the old fallacy of using spinal anesthesia in only poor general risks or nearly moribund patients should be practically extinct.

Statistics both here and abroad show that subarachnoid block is becoming more popular through its continuous use in clinics which are staffed with anesthetists specially trained and experienced in its use. Table 1 shows the number of cases in which operation was performed under spinal anesthesia in Boston, as compared with other clinics.

The use of spinal anesthetics requires an accurate and precise technic for uniform results. I strongly

Read before the Section on Miscellaneous Topics, Session on Anesthesia at the Eighty-Fifth Annual Session of the American Medical Association, Milwaukee, June 1, 1933.

been used and had better instruction been given as to its instillation. The claims made for its very complete control are plausible, but I have not used it for the past three years.

Toxicity is the first question that surgeons ask whenever a new drug is introduced into a clinic. The Boston City Hospital has adhered always to the principle of having a complete knowledge of the toxic action of these drugs which have been furnished by the manufacturer and carefully checked up by the hospital's research department. After a careful survey and use of the several drugs, we confined our study to the following four: procaine hydrochloride, neothesisin (benzoyl-gamma [2-methylpiperidine] propanol hydrochloride), nupercaine, and pantocain (para-butylaminobenzoyl-dimethyl ammoethanol hydrochloride).

Table 2 shows the comparative intravenous toxicity of the four drugs to be discussed, as obtained in cats by Dr. Stanley Nowak at the Boston City Hospital.

The relative toxicity of these drugs as observed clinically are in the order named: nupercaine, neothesisin, procaine hydrochloride and pantocain. The reactions peculiar to these drugs may be summed up briefly as depicted in table 3. A comparison of these drugs as to their relative difference in dosage and the length of anesthesia that they produce is shown in the accompanying chart.

The clinical usefulness of these drugs might well entail a lengthy discussion, but space will not permit. I shall enumerate briefly what I consider the practical use of these drugs. All operations below the diaphragm may be performed under spinal anesthesia. Apparently there is no limitation to the number of spinal anesthetics that a patient may undergo. To substantiate this statement, I have an authentic report that spinal

of these drugs in genito-urinary surgery I shall illustrate with cases in which there were definite complications other than the genito-urinary pathologic changes. A second stage prostatectomy was performed on a man, aged 78, who had endocarditis and myocarditis, with a previous history of six anginal attacks. We advised the first stage under local anesthesia and the second stage under spinal anesthesia using pantocain. In a case of renal calculi of the left kidney in a woman who was four months pregnant and weighed 180 pounds (81.6 Kg.) and was 5 feet (152.4 cm.) tall, the stones were removed, and she expects the baby next month. Another satisfactory case in this group was that in

DRUG	DOSEAGE	DURATION OF ANESTHESIA
PROCAINE	200 MG.	ONE HOUR
NEOTHESISIN	160 MG.	NINETY MINUTES
PANTOCAIN	20 MG.	TWO HOURS
NUPERCINE	10 MG.	THREE HOURS

Relative difference in dosage and length of anesthesia produced

which an octogenarian in his eighty-fourth year had a bladder stone the size of a goose egg and a prostate larger than a lemon removed under pantocain.

The relaxation afforded by spinal anesthesia renders operative procedures less difficult and minimizes the shock. The safety of these drugs as compared with general anesthetics is highly desirable in genito-urinary surgery because they do not seriously interfere with the kidney function.

Abdominal, gynecologic and orthopedic surgery of the lower half of the body vary a great deal in their types of operations and the length of time they consume. The use of spinal anesthesia in obstetrics may be dismissed with the statement that we do not advise its use unless a definite pathologic complication exists. We have used it seven times during the past year in private cases without a fatality. All of the patients had definite pathologic conditions of the chest.

All four of these drugs have been used on both males and females, the youngest patient was a girl, aged 8 years, while the oldest was the octogenarian. Their weights varied from 70 to 340 pounds (31.8 to 154.2 Kg.). Gastric and intestinal surgery of all types, including resections for carcinoma, are included in our series. Carcinoma of the sigmoid was completely removed in one stage. A right colectomy was done with anastomosis of the terminal ileum to the transverse colon. This patient is well and working. Gallbladder surgery was performed with great ease, as were the long and tedious umbilical and ventral herniotomies. We have a large series of the so-called double operations in gynecology. Included in the orthopedic operations may be mentioned two spinal fusions and many fractures, including one patient who had both femurs broken. All surgery of the lower extremities, including diabetic cases, and the different circulatory diseases in which spinal anesthesia was given for diagnosis, was performed under spinal anesthesia with satisfaction.

CONCLUSION

We have used each of these drugs in our series at the Boston City Hospital during the past sixteen months without a fatality. These drugs have been used separately and in different combinations for very definite purposes, with the result that we have formed a strong opinion that it is not necessary to mix them.

TABLE 3—Reactions to Drugs

	Pos- terior Root Block	An- terior Root Block	Change of Blood Pressure	Heart Rate	Respir- atory Depres- sion	Nausea	Head ache

Pantocain	Immedi- ate	Immedi- ate	Appre- ciable drop 0 to 10	No change	No	No	No

anesthesia was administered ten times within a period of fourteen months to one patient without any apparent deleterious effects.

Genito-urinary surgery offers a field in which we use spinal anesthesia as a routine, so satisfactory have been our results. Prostatectomies are performed with very small doses of the anesthetic drug. For example, we never use more than 60 (usually 50) mg. of procaine hydrochloride. When pantocain is used, the dosage varies from 8 to 10 mg. with satisfactory anesthesia. The first stage operation (a double vasectomy and cystostomy) with procaine hydrochloride shows a drop in blood pressure. The second stage, performed two

vidual case. Procaine hydrochloride and pantocain are the drugs frequently employed. Of these two drugs, pantocain offers everything that procaine hydrochloride will accomplish and has the advantage that it does *not* lower the blood pressure as does procaine. Furthermore, clinically, it is apparently less toxic than procaine hydrochloride, besides producing a longer and more satisfactory anesthesia.

520 Commonwealth Avenue

ABSTRACT OF DISCUSSION

DR FLOYD T. ROMBERGER, Lafayette, Ind. In a recent analysis of 1,600 consecutive operations under spinal anesthesia, I found that procaine hydrochloride was employed in 60 per cent, other drugs or combinations being used in the remaining 40 per cent. A study of my records shows that the onset of anesthesia is considerably slower with pantocain than with procaine, and still more delayed with nupercaine. Within safe limits, parallel dosage of pantocain alone or nupercaine alone apparently is more irregular and less predictable in effect and duration. Advantages obtained in combining procaine with pantocain or nupercaine are as follows: A small dose of procaine produces early anesthesia (within five minutes), sufficient pantocain may be added to prolong anesthesia to one and one-half hours, or enough nupercaine for two and one-half hours. The combination is safe for operations extending more than one hour. I am impressed with the opinion that the degree of circulatory change under spinal anesthesia is not due to any one particular drug but rather to the manner in which it is administered to the dosage employed, and to the number and kind of spinal nerve roots affected. Bad risks such as patients with intestinal obstruction, those bled white from a ruptured ectopic pregnancy, or those in shock from a perforated appendix or gastric ulcer, become higher and more profoundly anesthetized from equal dosage with any drug than do the robust; therefore these patients must be handled with the most conservative judgment and the keenest evaluation. Therein lies the secret of success or failure of life or of death.

DR FRANK A. KELL, Detroit. I should like to ask the author what the relative dose is generally between pantocain and procaine.

DR FRANK W. MARVIN, Boston. In regard to the relative dose in the average case, 75 mg. of pantocain is equivalent to 75 mg. of procaine. Experimentally in cats I found it seven times as toxic but clinically the results with blood pressure estimations and check ups showed that it had no more but in fact had even less reaction on the patient than procaine had.

DR KELL. In that proportion?

DR MARVIN. Yes, sir.

DR KELL. What is the usual interspace you use and how much mixture do you give it if any?

DR MARVIN. I usually inject in the third lumbar interspace. I have placed it in the twelfth dorsal and the first lumbar spaces but prefer the third lumbar. I first draw up 2 cc. of pantocain from the ampule into the syringe and then connect the syringe with the needle which has been placed in the subarachnoid space and withdraw 2 cc. of spinal fluid. This gives 4 cc. from which one can compute the dose one wishes to inject into the subarachnoid space.

DR M. L. AXELFORD, Cleveland. I should like to ask Dr. Marvin whether he has ever used or felt the need of using the prone position for improving the effect of spinal anesthesia.

DR MARVIN. I have used the Jones technique with nupercaine injecting it with the patient on the side never sitting up. The patient is then placed in the prone position from five to eight minutes which produces a sensory block. Then the patient is turned over to the dorsal position in a slight Trendelenburg position. The motor block gradually becomes established.

DR AXELFORD. Have you tried it with spinozaine?

DR MARVIN. No, it I have not used spinozaine for over five years. I must admit I am a great much smaller dose

of these drugs today than formerly. I do not think that I have ever used over 150 mg. of procaine, preferring to supplement whenever it has been necessary. That is probably the reason the mortality table has remained low.

CONJUNCTIVAL VESSELS

A. D. RUEDEMANN, M.D.

CLEVELAND

I am offering a report of a clinical study of the blood vessels of the conjunctiva, undertaken to determine to what extent their condition would aid in the diagnosis of diseases of the blood and vascular system. This study of the conjunctival capillaries was prompted by a desire to find earlier changes in the vessels than those seen in the retina in cases of vascular disease.

In his excellent description of the vascular system of the eye, Leber¹ (1903) described accurately the blood supply of the conjunctiva. He alluded to the superficial layer of vessels derived from the palpebral conjunctiva and the deeper layers coming from the anterior ciliaries. But the superficial layer itself really lies in two planes—a surface layer and a deeper layer. These two layers interchange capillary loops freely and form a rich capillary plexus at the limbus.

METHODS OF STUDY

The routine procedure for studying the vascular bed of the conjunctiva is to inspect the entire ocular conjunctiva by means of oblique illumination whereby the deeper vessels can easily be counted and their course and caliber noted. The superficial arterioles or loops can also be seen with the naked eye.

However, when one wishes to study the finer vessels, it becomes necessary to increase the illumination and to use higher magnification. The gross outline of the capillary field is best studied with a magnification of approximately sixty-eight times. When one wishes to study the minor vessels, it becomes necessary to use a still greater magnification.

Still further magnification is desirable. I have been working on a combination camera and microscope which I hope will reveal more detail. Most of this study has been made with a magnification of approximately 100, a 17 mm. eye-piece and 6 mm. objective, a Zeiss slit-lamp being used. This has been satisfactory for determining the following data:

FINDINGS IN THE CONJUNCTIVA

The deep layer of branches of the anterior ciliary arteries has little to do with the conjunctiva but more with the episcleral and scleral tissue. They form a separate system anastomose freely with one another but rarely with the vessels in the superficial planes, and penetrate the sclera from about 3 to 4 mm. from the limbus.

The superficial vessels are small and there are approximately twice or three times as many veins as arteries. The ratio of veins to arteries is not definitely 2:1 as described by Leber for the limbal plexus contains many more venules than arterioles or precapillary vessels. The number of the larger superficial vessels varies tremendously both as to arterioles and to venules while the deeper layer has only from six to twelve

From the Cleveland Clinic.

large vessels. The difference in size is even greater as the deep vessels are actually small arteries whereas the superficial vessels are arterioles and precapillaries, and are all comparatively small.

The remainder of the ocular conjunctiva is made up of rather loose areolar tissue and an intracellular semi-solid or semifluid tissue that, under high magnification, appears to have a flow. The fibroblasts making up the superficial tissue are loosely and indefinitely arranged, with few nerves and some lymph structures.

The superficial conjunctiva moves with the lids and globe, the deeper or episcleral tissue moves only with the globe. As the conjunctiva approaches the limbus, the layers approach each other and the upper and middle planes of vessels form a heavy capillary plexus, a few of the finer vessels going over into the cornea for a distance of a few millimeters. The so-called limbal loops have no definite arrangement and are usually merely a connection between the upper and lower vascular planes of the superficial layers. The limbal capillary layer is extremely interesting, in many cases it simulates the choroidcapillaries in the richness of its capillary bed. There is no regular arrangement of the capillary bed, it is not constant and has a wide variation even in normal persons.

Between the limbus and the fornices and the limbus and the external angle, there are few capillaries, the same holds true on the nasal side, except that the cruncle has a rich capillary plexus, although it is less easily studied because the areolar tissue is more dense than the ocular conjunctival tissue.

The superficial vessels afford an excellent field for the anatomic and physiologic study of the capillary system as well as a means for furthering knowledge concerning small vessel changes.

Lombard² (1911) studied capillary pressures and stimulated capillary study. Luedde,³ (1913) in a comprehensive study of 700 cases, demonstrated vascular changes in the conjunctiva, using a corneal microscope. My observations concur with his in regard to specific disease and his work apparently marked the first clinical pathologic study of the conjunctival vessels. It was not until 1921 that Krogh⁴ his co-workers and a host of others contributed much detailed research and clinical information on this branch of the vascular system. Krogh and his co-workers demonstrated that a capillary is a vessel made up of a single layer of endothelial cells which are flat polygonal cells with a single nucleus which is raised above the surface. These cells are fastened together loosely, but they have an added support in the so-called Rouget cells which support the endothelium as hoops support the staves of a barrel plus the added strength of vertical as well as horizontal fibers.

In 1928, Knusel and von Willer⁵ used vital staining to demonstrate the circulation in the conjunctiva. I also have studied the conjunctival capillaries in animals, both living and dead, with and without injection. Part of this study has been made on the eyes of rabbits into which injections were made during observation, and others on eyes into which injections were made after enucleation. Most of the work, however, was done on patients.

Rouget cells constitute the muscle or contractile coat of the capillary and are affected by light and by histamine, dionin and similar substances. The size of the capillaries varies greatly, ranging from a diameter accommodating a stream of approximately from four to six corpuscles to a diameter through which a single red corpuscle, 7 microns in size, has some difficulty in passing. One cannot differentiate the capillary walls except in certain instances, and then only by oblique illumination. However, it is possible to see the individual cells passing along the vessel. The speed with which the blood cells pass through the vessel is not constant. In instances of vascular disease the blood flows faster through some capillaries in the same tissue than through others, nor do all the capillaries contain blood at all times. However, contrary to some reports, no pulsation is seen in a normal capillary. The flow of blood is constant in most instances, sometimes, however it may be beaded or may be jerky, or it may stop entirely when the cells appear to congeal, then suddenly be swept through the vessels at a rapid rate. These fine capillaries anastomose freely, but the blood usually follows a definite channel. However, and not infrequently, blood may be exchanged from one capillary to another and then a reverse flow takes place. Within a capillary, the cells flow from wall to wall. The plasma layer, supposedly outside the central column of cells, does not seem to be present in the vessels studied.

In all the cases studied, it was impossible to demonstrate the formation of a vascular channel. However, on several occasions, I was able to observe what appeared to be the reopening of an old channel. In one case of severe inflammation many new capillaries were present, but I was unable to discern a newly-forming vessel. The caliber of an individual vessel may change in its course or at some point during observation. However, as stated previously, the channel seemed to be in fixed position. A capillary, like a larger blood vessel, has a place for itself.

A small vessel emptying into a larger one empties in the direction of flow of the vessel. These small vessels run for a long distance without any branching, especially on the arterial side. The entire picture is that of an attempt to get all the blood possible to the limbus and there to spread out.

There is a definite difference in the structure of the wall of these minute vessels, as one readily sees cells in the fine capillary vessels, whereas the small arteries do not permit direct study of the cells. The tortuosity of the deeper vessels, so often accepted as normal, varies tremendously, and one must classify certain types as strictly pathologic because of minute hemorrhages and a definite tendency to form varicosities. In the deeper vessels there is also much variation in the walls, in cases of hypothyroidism there is thickening of the wall. The dark area, sometimes seen around the vessel opening in the sclera, is not constant, nor does it always mark a vessel opening. These pigmented areas are seen elsewhere. There is a definite thickening of the tissue surrounding the vessel opening, and this may account for some of the stasis seen in certain cases.

CHANGES IN CONJUNCTIVA IN DISEASE

My interpretation of the changes noted in cases of known vascular disease and in some other pathologic conditions of the blood are as follows.

As to the nature of subconjunctival blood, according to the study of Krogh and others blood cells may pass

out between the endothelial cells in the absence of any break in the vessel wall. As noted before there seems to be a considerable number of cells and lymph in the tissue which makes it appear to flow in some cases. The subconjunctival hemorrhages are of two distinct types: first, the hemorrhage of diapedesis, in which a small collection of red cells (from 25 to 50 or more) lies outside a vessel, and second, the hemorrhage of pressure or obstruction. The latter is seen in cases of hypertension, in severe attacks of vomiting and in the subconjunctival hemorrhage that is widespread without apparent cause. However, more detailed study in the latter type of cases may reveal other minute hemorrhages of microscopic size. In a case of severe nausea and vomiting, the conjunctiva appeared congested both to the naked eye and with high magnification, the entire tissue was studded with pressure hemorrhage of the paint-brush type in miniature. The minute hemorrhage of diffusion and the minute hemorrhage of pressure disappear usually in twenty-four hours or less. It takes longer for the large hemorrhage of obstruction to disappear, often as long as ten days. The belief that with capillary hemorrhage the vessel becomes occluded is contrary to my observation. It was noted in several cases, one of severe vomiting and another of hemorrhage with pneumococcus conjunctivitis, that the small vessels continued to function without apparent interference to the flow. In larger hemorrhages with obstruction of flow or due to a major break, the surrounding capillaries do not appear to be disturbed, nor do they tend to send out new vessels into the involved area. At the end of from twenty-four to thirty-six hours, there appears what looks like a canalization through the hemorrhages. This appearance is caused by a clear zone around the functioning vessels, evidently because of disintegrated red blood cells or of fluid exuded from the functioning vessel by osmosis for the purpose of dissolving the excess protein. In either case, there is a definite breaking up of the cells with disappearance of all of the material of which they are composed. The involved vessels appear to become obliterated, and there may or may not be a new vessel. With present methods of study, this is difficult to decide. The few cases studied show that in spite of the fact that the area has been avascular for a period of time, a breaking down of the area does not result because of the nature of the tissue itself. This is not true in the retina where an area without blood supply dies in approximately six or seven minutes, and even though lack of collateral circulation is blamed for the tissue death this is dependent on the type of tissue and not on the degree of circulation.

Strangely enough obstructing thrombi or emboli are not uncommon, and one is led to conclude that the body may be bombarded with emboli without suffering any harm so long as the emboli or thrombi remain in silent areas as in the region of the ocular conjunctiva. These thrombi appear as small knobs and as obstructions to the flow in the capillary. In several instances I have observed canalization through the thrombus with the blood flowing out over the obstruction. Some thrombi block the minute vessel entirely, and in one instance there were several of these minute obstructions in a single field.

The speed of the blood is much more rapid through the capillaries in patients with hypertension and this speed may be used as a guide in diagnosis. The flow is sluggish in cases of extreme malaise and in one

instance in which the patient had recurring syncope, a low basal metabolic rate and a low blood pressure the blood flow through the capillaries was extremely slow, almost stagnant, and there was also a marked diminution in the amount of blood in any given area. As the clinical condition improved, with increase of the blood pressure and metabolism, both the volume and speed of flow in the capillary bed were augmented.

Although, as yet, the volume of capillary blood in a given area cannot be used as a basis for diagnosis, in one case of polycythemia the note was made that the entire capillary bed was loaded with blood which appeared to be packed. The reverse is true in cases of extreme anemia in which the blood volume appears to be definitely diminished. In a case of aplastic leukemia the flow was more granular and the entire tissue paler with the light reflected from the sclera very brilliant. The light reflected from the sclera is brighter in cases of anemia and hypertension in which the capillary bed is diminished than in cases of polycythemia, venous congestion, long-standing exophthalmos and edema.

In cases of hyperthyroidism, with and without exophthalmos, there is a congestion of the subconjunctival tissue. This is much greater in those cases of post-operative exophthalmos in which the deep vessels are extremely tortuous and varicose. With this congestion is associated a definite subconjunctival edema which varies in extent from microscopic to macroscopic. The congestion appears to be more on the venous side of the capillary bed than on the arterial, as does also the tortuosity.

My knowledge is too limited and the series of cases still too small for any definite notes regarding cases of papilledema. In cases of papillitis and retinitis, there is a definite increase in capillary volume, and in one case of retinal hemorrhage in which the vitreous was loaded and the red reflex was entirely absent, the blood in the capillary bed flowed slowly and the bed was heavily congested, whereas on the good side both the volume and the extent of the bed was much less.

The capillaries may come up from the deeper layers, as was noted in a case of recurring pterygium in which the new blood supply was definitely scleral and interstitial in origin, and no amount of surgical intervention or cauterization could eliminate recurrence. In patients with hyperthyroidism who have shown a postoperative increase in the degree of exophthalmos associated with hypometabolism the capillary bed and the fullness of the vessels was increased as well as the amount of conjunctival tissue while scattered along the larger deep vessels were what appeared to be fat droplets. These vessels showed a tortuosity out of proportion to the blood pressure and age of the patient. The appearance was that of stasis with slight edema. The retinal vessels usually do not reveal a difference in caliber or tortuosity, except in cases of malignant exophthalmos.

But the major role of study of the conjunctival capillaries is in their relation to vascular disease. The fine translation of Haab's work by Zentmeyer in Norris and Oliver's 'Diseases of the Eye' mentioned many of the minute changes that can be noted by this form of study. The work of Slocum on vascular disease and nephritis in 1916 and 1921 furthered the impor-

Zentmeyer, W. F. and Oliver, C. A. Study of the Fundus of the Eye. Philadelphia: J. B. Lippincott Company, 1927. 192 p. 400 illustrations. \$5.00.
Norris, C. A. Study of Ophthalmic Changes in Nephritis. J. A. M. A. 1916. Vol. 11, No. 1. 1916. A Study of the Fundus of the Eye. Trans. Am. Acad. Ophthalmol. 25: 1-10, 1922.

tance of study of the retinal vessels. More recently, Wagner, Bedell and others have continued to broaden the field and to define further the differentiation of vascular disease. It is hoped that study of the minute vessels of the eye will develop further the diagnostic ability of the oculist, and that it will aid in the diagnosis of these still perplexing problems. To learn that at present there is a wide difference of opinion regarding the classification of vascular diseases, one need only glance through any book on changes in the retinal vessel.

In this investigation, most changes were recorded purely on the basis of vascular study. No effort was made to read a diagnostic change into the vessels. The entire field is so new that thus far it is impossible to interpret the changes in the fine vessels as one does changes in the retinal vessels. They must be recorded as additional changes. A set of normal standards must be established as has been done in the case of the retinal vessels.

In some cases in which there apparently was no definite vascular disease except constriction and endarteritis, several fine to fairly large aneurysmal dilatations were found. These dilatations were fairly numerous in two cases of optic atrophy with a syphilitic background. No hint of aneurysmal change was discovered in the fundus.

Many similar aneurysms were seen in the minute conjunctival vessels of a man with senile arteriosclerosis and hypertension. He had had few retinal hemorrhages but had had repeated attacks of dizziness and syncope. On examination multiple hemorrhages of the pressure type and numerous aneurysmal dilatations were seen along the small vessels. In other cases, there have been similar changes. Evidently this dilatation is more common than the changes capable of detection in the retina.

Obliteration of the end-vessels, lessening of the capillary bed, straightening of the capillary branches and small hemorrhages are commonly seen in cases of arteriosclerosis. These were noted in several cases of senile sclerosis with central chorioretinitis. Capillary hemorrhages are much more common than are arteriolar hemorrhages, and while the retinal vessels may not appear to be sclerotic, the conjunctival capillaries may show changes. Further, venous congestion is much more common in arteriosclerosis than has been suspected heretofore. On the venular side, the fine venules and capillary bed are frequently full, while the arterial side is narrowed to a vessel with a lumen of a single red cell. The changes occur earlier in the conjunctival capillaries and are well established by the time the changes in the retinal vessel are sufficient for diagnostic purposes.

The diagnosis of essential hypertension is often difficult, and here also the fine conjunctival vessels show changes which present themselves later in the retinal vessels. The earliest change is a lessening of the capillary bed which increases as the disease progresses. Here also the venous side of the capillary bed usually is more congested than the arterial side.

No diagnostic changes have been noted in cases of diabetes principally because a sufficient number of cases has not been studied, and therefore many early changes cannot be differentiated. In children, no changes were noted, and in adults the changes were mainly those characteristic of vascular disease. However, further study must be made before any just conclusion can be drawn.

Cases of vascular disease with hypertension are very common. The discussion as to whether the pressure or the vascular disease is primary can be solved only by continued study, with improved experience in recognizing the earliest changes. Certainly there is no better place to study vascular changes than in the conjunctiva where the vessels are close to the surface. The fine vessels show early changes (pigtail tortuosity) followed by definite straightening, minute aneurysmal changes and numerous sacculations. The latter are not like the so-called venous sinus spaces, and they persist after the instillation of epinephrine. They are constantly present and evidently are obstructive. The lessening of the capillary bed is definite and diagnostic, as checked by the effects of intravenous injections of histamine. The vessels in the capillary bed may be reduced to a small number while not many changes are present in the fundus. The loss in the number of vessels, their narrowing and the venous tortuosity is typical of malignant hypertension. Small hemorrhages, some of venular origin, also frequently are seen in cases in which no hemorrhages or posthemorrhage cotton spots are noted in the fundus; there is no dilatation with arteriovenous compression, and the arteriovenous crossings are without apparent interference. In a few cases, vessels have been recoiled and looped on themselves, and here they present ampullae which may simulate arteriovenous compression dilatation. This is noticeable in the horizontal vessels, especially of the deep nasal group which frequently may become varicose and double on themselves.

As has been stated, in hypertension the cells flow through the capillaries more rapidly but without discernible pulsation. In two cases, in which distinct pulsations showed where a secondary vessel left a main branch, the impact could be seen only at the vessel opening. In these cases the sclerae appeared whiter, and the light reflected from them was much more brilliant than in normal cases.

Further study, under higher magnification, should reveal still other early vascular changes. The use of red-free light reveals changes I have not yet attempted to classify.

SUMMARY

1 The vascular system of the conjunctiva lies in two planes, one, the superficial layer, and the other, the branches of the anterior ciliary arteries.

2 There is a heavy capillary plexus at the limbus.

3 Speed of flow, size of vessels and the action of various substances can easily be studied in the conjunctival vessels. This field apparently offers an excellent location for physiologic vascular study, as all action is in the living tissue in normal position and under controlled conditions.

4 Pathologically, minute hemorrhages are commonly found.

5 Aneurysmal dilatations are more common than in the retina.

6 Thrombi and emboli apparently are present more commonly than had been suspected.

7 Decrease of the capillary bed in the conjunctiva has been coincident with the similar change shown by the histamine flare test.⁸

8 Although time-consuming, it seems likely that when normal standards have been established, the study will reveal sufficient information to warrant investigation.

⁸ Ernstene, A. C. and Snyder, M. Histamine Flare Test in Malignant Hypertension. Personal communication to the author.

tion of the conjunctival capillaries in all cases in which blood or vascular disease is suspected

9 The vessels can be measured and counted and, to date, the patients have experienced no deleterious effect from the illumination

ABSTRACT OF DISCUSSION

DR. ARTHUR J BEDELL, Albany, N Y All ophthalmologists are familiar with the recognized methods of examining blood vessels the microscopic study of those beneath the finger-nail, the critical scrutiny and stereoscopic photography of the retinal vessels, the microscopic examination of biopsy specimens, and the inspection of the conjunctiva Each procedure has some advantages over the others, but in each one some essentials are lacking for the complete understanding or portrayal of the vessels To photograph the minute changes in the blood vessel walls of the bulbar conjunctiva is a most exacting task For many years I have used the Druner camera illuminating the field with a beam from the arc lamp focused through a quartz lens but even this method is of limited value when high magnifications are attempted The author has avoided the technical difficulties which surround the inspection of the conjunctival blood vessels To examine the vessels on a movable object, the eyeball requires an extremely well trained patient observer With the low magnifications the blood stream can be readily followed, but it is practically impossible to see the vessel wall When the 100 magnification is used the constant oscillation of the globe is so great that only in the well controlled patient can one occasionally see wall changes One can, however see vessel dilatations aneurysmal sacs irregularities of lumen difference in the rapidity of

box cars the cells Comment on the position of the cellular elements of the blood in the capillary stream is to be made with even more uncertainty, for it is not yet possible to correlate the changes one sees with known pathologic pictures

DR A D RUEDEMANN, Cleveland I want to quote a statement made in the Section on Practice of Medicine by Dr Wright to the effect that one should not feel disappointed if one is not able to make a diagnosis from the study of capillary vessels in the first fifty cases I have found that to be true because for some nine months I was unable to reach a diagnosis from the study of these conjunctival vessels

Clinical Notes, Suggestions and New Instruments

AN ECONOMICAL COVER FOR LABORATORY INSTRUMENTS

R H McCLELLAN M D PITTSBURGH

In localities in which there is a large amount of dust in the air a protective covering for such instruments as the microscope colorimeter and microtome becomes a necessity The usual glass bell jar is heavy, awkward expensive and easily broken It is in the hope that others will find it advantageous to use that a description of a cover I have devised is presented in the accompanying illustrations

Fig 1—Cover for colorimeters

Fig 2—Cover for microtome

Fig 3—Cover for microscope

blood stream propulsion direction of flow and many other details involved in this investigation The survey of the conjunctival vessels of the limbus shows that in health they extend for a very short distance a fraction of a millimeter over the cornea Under normal conditions they can be traced at the limbus as loops or palisades At least three layers of conjunctival vessels can be seen during slit lamp examination and the penetrating ciliary arteries can be readily distinguished from the superficial or true conjunctival circulation It is with considerable diffidence that one can make any definite pronouncements as to the etiologic factors that control the character of the pulsation in the blood vessels In the large vessels the blood flows in a constant stream In the smaller ones there is a definite propulsive throb the blood seems to move forward and stop so suddenly as to give the impression of regurgitation In the smallest vessels the blood stream is interrupted and as the corpuscle tumbles over one another they give the impression of a long train of freight cars moving in the distance The flat cars represent the spaces without corpuscles and the

Discarded noninflammable roentgenogram are placed in warm solution of sodium bicarbonate and the photosensitive film is removed, care being taken not to scratch the base Accurate measurements of the proposed covers are made and a design worked out on paper so as to utilize the size of film on hand and to make as few joints as possible The film is ruled with a glass marking pencil and cut to size At the joints it is necessary to provide for a flap of one half inch The film is bent to shape and the angle started by laying the flat sheets on several layers of towels and scoring them at the proper place with minimum pressure a round ended instrument being used The angles are then completed by careful manipulation by hand An ordinary ticket punch is used to perforate the sheets at the proper places for assembly The final step is to insert and bend into place small round headed brass fasteners A convenient handle is readily made with the same material and fastened to the top with brass fasteners The cost of material

From the John C. Overman Memorial Research Foundation, St. Margaret's Memorial Hospital

and the time required to make these covers for almost any of the usual apparatus found in clinical laboratories is negligible. I have found them convenient and presentable combining low cost and light weight with the advantages of glass, such as transparency, but without breakage.

PEDUNCULATED LIPOMA OF UNUSUAL SIZE

MURRAY N. HADLEY, M.D., INDIANAPOLIS

A white man, aged 65, a farm laborer entered the University Hospital because of a foul odor which complicated a large tumor mass hanging from the left gluteal region. The accompanying illustration shows the size and location of the tumor. It had been present fourteen years, beginning as a small growth just beneath the skin.

Physical examination was essentially negative the only departure from normal being the pupils, which were somewhat sluggish to light, an early senile cataract and a soft diastolic blow heard over the aortic area.

Ulcerated, pedunculated tumor of left buttock.

The tumor was hard and somewhat irregular and had three open ulcers on the posterior and inferior surfaces. The pedicle was soft and pliable and gave no evidence of infiltrating the deeper structures. The mass was excised with a diathermic knife, and wound healing by first intention followed. Gross examination and section showed it to be a lipoma and that diagnosis was confirmed by the laboratory report on a stained section from the tumor.

As this patient was a man of normal mentality in one of his social status, living in an average rural community, the question arises: Why did he delay fourteen years to seek relief which was available without cost? The reason is probably to be found in the part which stupidity plays in preventing people from getting adequate medical care. Any system of medical practice, short of compulsion, must in the last analysis depend on an enlightened public who, when the need arises will avail itself of the benefits of scientific medicine.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
PAUL NICHOLAS LEECH, Secretary

DIAMPYSAL NOT ACCEPTABLE FOR N N R

In 1931 the Council on Pharmacy and Chemistry took up the consideration of Ampysal (Osten Chemical Corporation, New York) at the request of the manufacturer. Before the Council's referee had reported on it the firm stated that the name of the product had been changed to Diampysal. According to the information submitted by the manufacturer, the product is another pyridine derivative with sufficient germicidal properties to arouse interest in it as a chemotherapeutic agent in bacterial infections. It is stated to be ortho oxy-benzo 2,6-diaminopyridine and is recommended by the manufacturer for use in a wide number of infections. The laboratory reports submitted by the firm to back up the claims indicate that the product may have some promise but among the case reports submitted there are few, if any, well controlled clinical studies and totally inadequate evidence from an etiologic standpoint, to justify the statement that the drug is effective in so many different types of infection. The Council postponed consideration of Diampysal (then Ampysal) to await (1) presentation of more convincing evidence of the effectiveness of the compound, (2) modification of the commercial literature on the product to conform with the demonstrable results produced by the use of the compound, (3) favorable report of the Council's Committee on Nomenclature on the name, and (4) favorable report by the A. M. A. Chemical Laboratory on the chemical claims.

In July, 1932 the Osten Chemical Corporation presented additional evidence in favor of the product under the new name Diampysal which is stated to be a new molecule obtained by chemical interaction of Orthohydroxybenzoic acid with 2,6-Diaminopyridine. The firm presented additional clinical reports and testimonials which again represent uncontrolled observations and do not supply the required additional clinical evidence of the value of Diampysal. The firm stated that no claims were to be made for the product but it has prepared new directions for the use of Diampysal which contain the direct claim that it is a chemotherapeutic agent and specify the inflammatory conditions in which its use is recommended. These "directions" obviously constitute claims, and they are not supported by convincing evidence. As evidence in favor of the use of a proprietary name the firm submitted copies of certificates of registration from the United States Patent Office, which of course, is not the kind of evidence required by condition 3 of the Council's first report. The chemical claims may be referred to the A. M. A. Chemical Laboratory, if necessary. Without passing on the question of the name or of the chemical composition therefore the Council declared Diampysal unacceptable for New and Nonofficial Remedies because of insufficient evidence of its therapeutic value.

When the preceding report was submitted to the Osten Chemical Corporation, the firm asked for further opportunity to make clinical tests of the preparation and on agreement of the firm to avoid active propaganda the Council agreed to withhold publication of the report for a certain period. Since that time the firm has submitted a number of testimonial letters from physicians recording their experience with Diampysal in private practice and also case reports from various physicians. The testimonials lacked details and evidence of carefully controlled observation as did the letters referred to in the previous report which were not held to be acceptable evidence. The reports appeared to the Council no more convincing than the previous material which had been judged to be inadequate to support the claims for Diampysal.

The Council therefore voted to reaffirm its declaration that Diampysal is unacceptable for inclusion in New and Nonofficial Remedies because its therapeutic value is not supported by convincing evidence and adopted this addition to its previous statement.

Committee on Foods

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS

RAYMOND HERTWIG Secretary

TOLERANCES FOR ARSENIC, COPPER AND LEAD IN FOODS

Arsenic, copper and lead compounds are highly toxic. Their presence over certain trace quantities in foods may seriously endanger life or health. These elements occur naturally in infinitesimal quantities in many foods, but the quantities are not of physiologic concern. Foods, however, may be dangerously contaminated with these elements by insecticide sprays, chemicals used in the manufacture of foods, factory processing equipment, and other means.

Proper precautions should be taken in the culture, treatment, preparation, processing, packing, manufacture or preservation of foods that they shall not be contaminated with arsenic, copper or lead compounds. Equipment and materials used in the manufacture of prepared foods, and containers in which they are packed, should be of such composition as will not possibly contaminate foods with these elements.

Foods to be eligible for acceptance shall not contain arsenic, copper and lead in excess of the tolerances established by the United States Department of Agriculture:

- (a) 106 parts of arsenic (as As) per million of food [14 parts of arsenic (as As₂O₃) per million of food]
- (b) 30 parts of copper (as Cu) per million of food
- (c) 2 parts of lead (as Pb) per million of food

ACCEPTANCE WITHDRAWN
CEREO COMPANY'S SOY BEAN GRUEL FLOUR

Manufacturer—Cereo Company, Tappan, N. Y.

Discussion—The manufacturer has not provided the complete list of the ingredients and quantities thereof, chemical analysis, specifications or description of materials used in its preparation, and description of manufacture being required for all accepted foods by the Committee's present Rules and Regulations. The previous acceptance of the Council on Pharmacy and Chemistry and later of the Committee on Foods is therefore being withdrawn, the product will no longer be listed among the Committee's accepted foods.

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMOTION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG Secretary

- (a) GILSTERS BEST FLOUR (BLEACHED)
- (b) GILSTERS FEATHERLITE PLAIN FLOUR (BLEACHED)
- (c) GILSTERS MOTHER'S JOY PLAIN FLOUR (BLEACHED)

Manufacturer—Gilster Milling Company, Mill Steelville, Ill. Office: Chester, Ill.

Description—(a) Soft winter wheat short patent flour bleached.

(b) and (c) Soft winter wheat long patent flours bleached.

Manufacture—Selected soft winter wheat is cleaned, scoured, tempered and milled by essentially the same procedures as described in THE JOURNAL, June 18, 1932, p. 2210. Chosen flour streams are blended and bleached with a mixture of calcium peroxide and benzoyl peroxide and with chlorine.

Claims of Manufacturer—For bread, biscuit, cake and pastry.

EATMOR CRANBERRIES PAMPHLET "FOOD VALUE OF CRANBERRIES AND CRANBERRY SAUCE"

Sponsor—American Cranberry Exchange, Inc., New York.

Discussion—The pamphlet briefly presents the chemical analysis including the mineral constituents, nutritive and physiologic values, and the vitamin content of fresh cranberries. Ingestion of normal amounts scarcely affects the body's alkali reserve. The acidity of the urine is slightly increased by the elimination of the small amounts of benzoic and quinic acids present in the fruit but there is nothing to indicate that the increase has any physiologic significance. The preponderant fruit acids are citric and malic. Cranberries are a good source of vitamin C and contain small amounts of vitamin A and iodine. From 3 to 4 Gm. daily is required to provide the vitamin C for guinea-pigs for normal growth and to protect fully from scurvy. About 80 per cent of the vitamin C is retained in whole fruit cranberry sauce. A pound of cranberries makes about 2½ pounds of whole fruit cranberry sauce with a sugar content of from 40 to 45 per cent.

SMITH'S BEST FLOUR (BLEACHED)

Manufacturer—Commander-Larabee Corporation, Minneapolis.

Description—Hard winter wheat patent flour (bleached).

Manufacture—Selected hard winter wheat is cleaned, tempered and milled by essentially the same procedure as described in THE JOURNAL, June 18, 1932, page 2210. Chosen flour streams are blended and bleached with nitrogen trichloride (one twenty-eighth ounce per 196 pounds) and with a mixture of benzoyl peroxide and calcium phosphate (three-fourths ounce per 196 pounds).

Claims of Manufacturer—A patent flour primarily intended for family use.

D-ZERTA

A SACCHARIN-SWEETENED GELATIN DESSERT, SUGAR AND CARBOHYDRATE FREE, FRUIT ACID—FRUIT FLAVOR (LEMON, ORANGE AND RASPBERRY)—ADDED NATURAL COLOR.

Manufacturer—The Jell-O Company, Inc., Le Roy, N. Y. Division of General Foods Corporation, New York.

Description—A gelatin dessert preparation containing gelatin, tartaric acid, saccharin, fruit flavors (lemon and orange oils and true raspberry extract), and added natural coloring (curcumin, cochineal and orcein).

Manufacture—The ingredients in solution are admixed in formula proportions, dried and packed.

Analysis (submitted by manufacturer)—

Moisture	per cent
Ash	6.7
Fat	0.7
Protein (N x 5.55)	0.0
Saccharin	75.3
Crude fiber	1.4
Carbohydrates	0.0
Tartaric acid	0.0
	15.9

Calories—3.6 per gram, 102 per ounce.

Claims of Manufacturer—For low carbohydrate diets. Each package envelop contains:

Protein (gelatin)	2 grams
Fat	None
Carbohydrates	None
Saccharin	None
Tartaric acid	0.04 gram
Fruit flavor (carbohydrate free)	0.48 gram
Natural color (carbohydrate free)	q. s.
Calories	8

V. J. C. PURE FOOD BRAND JUICE OF FANCY WHOLE TOMATOES

Distributor—Northern Jobbing Company, St. Paul.

Packer—Vincennes Packing Corporation, Vincennes, Ind.

Description—Pasteurized tomato juice with added salt retains in high degree the vitamin content of tomatoes. The can is also of Old Vincennes Tomato Juice (THE JOURNAL, Feb. 20, 1932, p. 649).

SATURDAY, NOVEMBER 4, 1933

THE SESQUICENTENNIAL OF THE HYDROGEN BALLOON

The recent celebration in France of the one hundred and fiftieth anniversary of the landing of the first balloon inflated with hydrogen may seem on casual consideration to have no special interest to medicine. This is, however, by no means the case. Man's conquest of altitude has been continued both by land and in the air during these many intervening decades. In addition to the physical and technical difficulties involved in ascents by land and air there remains the equally important consideration of life at high altitudes. Existence in the upper reaches of the atmosphere encounters the problems of the lowered barometric pressure with its lowered partial pressure of the indispensable oxygen. Altitude sickness presently becomes a reality that may be so mild as to be overlooked by the unobservant person or so severe as to threaten life itself.

In Europe where mountain climbing had long been a popular sport, the scientific aspects of mountain sickness were recognized by the organization of special laboratories such as the one on Monte Rosa. In this country, the exigencies of the World War served more than any other factor to stimulate scientific interest in the human problems of the conquest of altitude. The value of the human machine in aviation excited the serious attention of those responsible for the success of airplane flight. The manifold details of the medical aspects of aviation were soon recognized. Thus a member of the Medical Research Laboratory of the War Department's Division of Military Aeronautics¹ pointed out that the physiologic effects of altitude on man and other animals have a threefold interest. The purely scientific aspects of life under conditions of low barometric pressure are themselves deserving of careful investigation, the fact that altitude plays a part in therapeutics and forms a feature of climatology, as applied by medicine, furnishes another reason why

the subject should be placed on a rational basis, while the coming into prominence of aviation, which requires a man to ascend into the air as the bird, frequently to moderate and sometimes to great altitudes, furnishes a third reason why one should know what constitutes fitness for life in rarefied air. As soon as an attempt is made to interpret the physiologic phenomena of altitude in terms of their causes, difficulties arise. The reason for contradictory theories is to be found in the complexity of the factors that enter into the environment at high altitudes. Among the climatic variables are the low atmospheric pressure with its low partial pressure of oxygen, the peculiarities of the sunshine, low temperature and humidity, the high wind, the electric conditions of the atmosphere, and ionization.

The principal difficulty at high altitudes, whether in the ascents of the Himalayas or in the penetration of the stratosphere, lies in the increasing lack of oxygen as altitude is gained. This presents the menace of anoxemia. The factors effective in compensation to this are increased respiration, chemical alterations in the blood and augmented hemoglobin. The respiratory change ranks first because by this means the partial pressure of the oxygen in the lungs is raised above what it would normally be at the altitude. This favors not only the absorption of oxygen in the lungs but also, after acclimatization, the passage of oxygen from the blood to the tissues. Since the alkalosis resulting from augmented breathing interferes with the passage of oxygen from the blood to the tissues, it cannot be questioned that the restoration of the normal hydrogen ion content by the elimination of the excess of alkali constitutes a compensatory process of almost if not equal importance with the increase in breathing.

Acclimatization to height whereby the oxygen-carrying capacity of the blood is gradually enhanced through physiologic adjustments is one of the features that has helped to overcome the handicaps encountered. Furthermore, surplus oxygen can be transported along with man and his machines and supplied artificially to each as the atmosphere becomes too rarefied. Through such aids man has already ascended considerably beyond 27,000 feet on foot in the highest peaks of the world until the conquest of Mount Everest has almost been made, whereas the latest balloon flights have far exceeded the 8 mile rises of pilots in airplanes. Such feats involve the need of a degree of environmental "air conditioning" in comparison with which the recent noteworthy achievements in altering the atmospheric conditions in theaters, railway trains, offices and homes seem modest.

Nearly a century elapsed after the first successful hydrogen balloon landing before the essential cause of altitude sickness was established. The distinction of a satisfactory explanation belongs to the French physiologist Paul Bert whose investigations are summarized in his well known book *La pression barometrique*. In

the subject should be placed on a rational basis, while the coming into prominence of aviation, which requires a man to ascend into the air as the bird, frequently to moderate and sometimes to great altitudes, furnishes a third reason why one should know what constitutes fitness for life in rarified air. As soon as an attempt is made to interpret the physiologic phenomena of altitude in terms of their causes, difficulties arise. The reason for contradictory theories is to be found in the complexity of the factors that enter into the environment at high altitudes. Among the climatic variables are the low atmospheric pressure with its low partial pressure of oxygen, the peculiarities of the sunshine, low temperature and humidity, the high wind, the electric conditions of the atmosphere, and ionization.

The principal difficulty at high altitudes, whether in the ascents of the Himalayas or in the penetration of the stratosphere, lies in the increasing lack of oxygen as altitude is gained. This presents the menace of anoxemia. The factors effective in compensation to this are increased respiration, chemical alterations in the blood and augmented hemoglobin. The respiratory change ranks first because by this means the partial pressure of the oxygen in the lungs is raised above what it would normally be at the altitude. This favors not only the absorption of oxygen in the lungs but also, after acclimatization, the passage of oxygen from the blood to the tissues. Since the alkalosis resulting from augmented breathing interferes with the passage of oxygen from the blood to the tissues, it cannot be questioned that the restoration of the normal hydrogen ion content by the elimination of the excess of alkali, constitutes a compensatory process of almost if not equal importance with the increase in breathing.

Acclimatization to height whereby the oxygen-carrying capacity of the blood is gradually enhanced through physiologic adjustments is one of the features that has helped to overcome the handicaps encountered with man and his machines and supplied artificially to each as the atmosphere becomes too rarefied. Through such aids man has already ascended considerably beyond 27,000 feet on foot in the highest peaks of the world until the conquest of Mount Everest has almost been made, whereas the latest balloon flights have far exceeded the 8 mile rises of pilots in airplanes. Such feats involve the need of a degree of environmental air conditioning² in comparison with which the recent noteworthy achievements in altering the atmospheric conditions in theaters, railway trains, offices and homes seem modest.

Nearly a century elapsed after the first successful hydrogen balloon landing before the essential cause of altitude sickness was established. The distinction of a satisfactory explanation belongs to the French physiologist Paul Bert, whose investigations are summarized in his well known book *La pression barometrique*. In

the words of Haldane,² Paul Bert's experiments, made partly on animals and partly on himself in a steel chamber, showed conclusively that, whatever other conditions may contribute to the production of mountain sickness, the essential cause is diminution in the partial pressure or concentration of oxygen in the air inspired. At high altitudes this partial pressure is reduced along with the reduction in total atmospheric pressure, though the percentage composition of the air is exactly the same at high altitudes as at sea level. If the lowering of the oxygen pressure is prevented by adding pure oxygen to the air, the lowering of barometric pressure has no effect.

THE NATURE OF POSTVACCINIAL ENCEPHALITIS

The occurrence of encephalitis after smallpox vaccination has attracted the anxious interest of physicians and public health authorities. Since Lucksch¹ in 1924 reported three cases of postvaccinal encephalitis there has been a growing literature on this subject, especially from England, Holland and Germany. The condition is characterized clinically by a definite incubation period of from ten to twelve days, hyperacute onset, headache, vomiting, fever, paralysis, and death in from 35 to 50 per cent of the cases. Anatomically there is a diffuse encephalomyelitis. When recovery occurs it is usually complete, though there have been reports of mental deterioration and residual paralysis. There is, of course, no established relationship of any kind between this condition and various types of epidemic encephalitis.

Infection of the nervous system after vaccination is no new fact. It has occurred in times past but has been overlooked (as many cases of so-called tetanus) or its clinical significance has not been appreciated. In recent times there has been an apparent increase of such complications, apparent because it may mean only increased recognition and reporting of cases.

Judging from the reports, postvaccinal encephalitis may occur at any age. In England, children of school age were most frequently affected, in Holland the pre-school ages (from 3 to 7 years) suffered most, and in Germany the first two years of life were most involved. Eckstein³ ascribes the disparity in age incidence to the difference in vaccination laws and methods. He denies the existence of a special age predisposition, although he observes that in the first year of life there is a relative immunity against nervous complications. Experienced vaccinators are agreed that young infants tolerate vaccination better than older children. In some instances a familial incidence has been observed, several members of a family being affected, whether the vacci-

nations have been performed simultaneously or at separate intervals. This indicates the importance of a constitutional factor. Because of such observations, Thomsen⁴ thinks that a definite personal predisposition seems to be necessary for the development of postvaccinal encephalitis.

At present the specific exciting cause of this form of encephalitis is not known, but several plausible theories have been suggested and each has its discrepancies. Part of the difficulty is due to lack of knowledge about filtrable viruses. Boycott,⁵ in summing up available information in this field, states that no filtrable virus has grown and propagated in artificial mediums. For this purpose young growing tissue cells are necessary, since filtrable viruses seem to be obligatory intracellular parasites. This may have a bearing on the peculiarities of their immunologic reactions. Boycott observes that it is perhaps unnecessary for filtrable viruses to produce free toxins, since they live within the cells, and that mechanical disorganization of the cellular structure might well be the cause of the ensuing reactions. He thinks that the general symptoms are caused, as in bacterial infections, by substances derived from the injured cells of the host, and these would also account for the local inflammatory response.

The recent report⁶ on the isolation of a crystallized filtrable virus, the etiologic factor of mosaic disease of tobacco, is revolutionary in its implications and tends to throw doubt on the conception that poliomyelitis, smallpox and numerous other virus infections are due to living agents. The apparent evidence that a specific protein, which in itself is incapable of multiplying, may function as a disease germ when placed in "symbiosis" with normal cells may explain why the filtrable viruses cannot be cultivated on artificial mediums. In the course of this study, Vinson⁶ and his colleagues obtained colloidal crystals that were uniform in appearance and moderately infectious and retained their infectivity on recrystallization.

In the light of these studies on the filtrable viruses, it is of interest to consider present views as to the cause of postvaccinal encephalitis. The most reasonable hypotheses at present are the following: 1. The vaccine virus is the direct cause of postvaccinal encephalitis. 2. Vaccination induces activation of some other virus latent in the body. 3. The encephalitis is the clinical expression of a local allergic (anaphylactic) reaction of the central nervous system in which the virus acts as a sensitizing agent.

Several objections have been raised to the first theory. Encephalitis occurs in a relatively small proportion of the vaccinated persons (1/100,000 in Germany, 1/4,000 in Holland and 1/48,000 in England), whereas gener-

THE SESQUICENTENNIAL OF THE HYDROGEN BALLOON

The recent celebration in France of the one hundred and fiftieth anniversary of the landing of the first balloon inflated with hydrogen may seem on casual consideration to have no special interest to medicine. This is, however, by no means the case. Man's conquest of altitude has been continued both by land and in the air during these many intervening decades. In addition to the physical and technical difficulties involved in ascents by land and air there remains the equally important consideration of life at high altitudes. Existence in the upper reaches of the atmosphere encounters the problems of the lowered barometric pressure, with its lowered partial pressure of the indispensable oxygen. Altitude sickness presently becomes a reality that may be so mild as to be overlooked by the unobservant person or so severe as to threaten life itself.

In Europe, where mountain climbing had long been a popular sport, the scientific aspects of mountain sickness were recognized by the organization of special laboratories such as the one on Monte Rosa. In this country, the exigencies of the World War served more than any other factor to stimulate scientific interest in the human problems of the conquest of altitude. The value of the human machine in aviation excited the serious attention of those responsible for the success of airplane flight. The manifold details of the medical aspects of aviation were soon recognized. Thus a member of the Medical Research Laboratory of the War Department's Division of Military Aeronautics¹ pointed out that the physiologic effects of altitude on man and other animals have a threefold interest. The purely scientific aspects of life under conditions of low barometric pressure are themselves deserving of careful investigation, the fact that altitude plays a part in therapeutics and forms a feature of climatology, as applied by medicine, furnishes another reason why

the subject should be placed on a rational basis, while the coming into prominence of aviation, which requires a man to ascend into the air as the bird, frequently to moderate and sometimes to great altitudes, furnishes a third reason why one should know what constitutes fitness for life in rarefied air. As soon as an attempt is made to interpret the physiologic phenomena of altitude in terms of their causes, difficulties arise. The reason for contradictory theories is to be found in the complexity of the factors that enter into the environment at high altitudes. Among the climatic variables are the low atmospheric pressure with its low partial pressure of oxygen, the peculiarities of the sunshine, low temperature and humidity, the high wind, the electric conditions of the atmosphere, and ionization.

The principal difficulty at high altitudes, whether in the ascents of the Himalayas or in the penetration of the stratosphere, lies in the increasing lack of oxygen as altitude is gained. This presents the menace of anoxemia. The factors effective in compensation to this are increased respiration, chemical alterations in the blood and augmented hemoglobin. The respiratory change ranks first because by this means the partial pressure of the oxygen in the lungs is raised above what it would normally be at the altitude. This favors not only the absorption of oxygen in the lungs but also, after acclimatization, the passage of oxygen from the blood to the tissues. Since the alkalosis resulting from augmented breathing interferes with the passage of oxygen from the blood to the tissues, it cannot be questioned that the restoration of the normal hydrogen ion content by the elimination of the excess of alkali, constitutes a compensatory process of almost if not equal importance with the increase in breathing.

Acclimatization to height whereby the oxygen-carrying capacity of the blood is gradually enhanced through physiologic adjustments is one of the features that has helped to overcome the handicaps encountered. Furthermore, surplus oxygen can be transported along with man and his machines and supplied artificially to each as the atmosphere becomes too rarefied. Through such aids man has already ascended considerably beyond 27,000 feet on foot in the highest peaks of the world until the conquest of Mount Everest has almost been made, whereas the latest balloon flights have far exceeded the 8 mile rises of pilots in airplanes. Such feats involve the need of a degree of environmental "air conditioning" in comparison with which the recent noteworthy achievements in altering the atmospheric conditions in theaters, railway trains, offices and homes seem modest.

Nearly a century elapsed after the first successful hydrogen balloon landing before the essential cause of altitude sickness was established. The distinction of a satisfactory explanation belongs to the French physiologist Paul Bert, whose investigations are summarized in his well known book *La pression barometrique*. In

the words of Haldane,² Paul Bert's experiments, made partly on animals and partly on himself in a steel chamber, showed conclusively that, whatever other conditions may contribute to the production of mountain sickness, the essential cause is diminution in the partial pressure or concentration of oxygen in the air inspired. At high altitudes this partial pressure is reduced along with the reduction in total atmospheric pressure, though the percentage composition of the air is exactly the same at high altitudes as at sea level. If the lowering of the oxygen pressure is prevented by adding pure oxygen to the air, the lowering of barometric pressure has no effect.

THE NATURE OF POSTVACCINIAL ENCEPHALITIS

The occurrence of encephalitis after smallpox vaccination has attracted the anxious interest of physicians and public health authorities. Since Lucksch¹ in 1924 reported three cases of postvaccinal encephalitis there has been a growing literature on this subject, especially from England, Holland and Germany. The condition is characterized clinically by a definite incubation period of from ten to twelve days, hyperacute onset, headache, vomiting, fever, paralysis, and death in from 35 to 50 per cent of the cases. Anatomically there is a diffuse encephalomyelitis. When recovery occurs it is usually complete, though there have been reports of mental deterioration and residual paralysis. There is, of course, no established relationship of any kind between this condition and various types of epidemic encephalitis.

Infection of the nervous system after vaccination is no new fact. It has occurred in times past but has been overlooked (as many cases of so-called tetanus) or its clinical significance has not been appreciated. In recent times there has been an apparent increase of such complications, apparent because it may mean only increased recognition and reporting of cases.

Judging from the reports, postvaccinal encephalitis may occur at any age. In England, children of school age were most frequently affected, in Holland the pre-school ages (from 3 to 7 years) suffered most and in Germany the first two years of life were most involved. Eckstein² ascribes the disparity in age incidence to the difference in vaccination laws and methods. He denies the existence of a special age predisposition, although he observes that in the first year of life there is a relative immunity against nervous complications. Experienced vaccinators are agreed that young infants tolerate vaccination better than older children. In some instances a familial incidence has been observed, several members of a family being affected whether the vacci-

nations have been performed simultaneously or at separate intervals. This indicates the importance of a constitutional factor. Because of such observations, Thomsen³ thinks that a definite personal predisposition seems to be necessary for the development of postvaccinal encephalitis.

At present the specific exciting cause of this form of encephalitis is not known, but several plausible theories have been suggested and each has its discrepancies. Part of the difficulty is due to lack of knowledge about filtrable viruses. Boycott,⁴ in summing up available information in this field states that no filtrable virus has grown and propagated in artificial mediums. For this purpose young growing tissue cells are necessary, since filtrable viruses seem to be obligatory intracellular parasites. This may have a bearing on the peculiarities of their immunologic reactions. Boycott observes that it is perhaps unnecessary for filtrable viruses to produce free toxins, since they live within the cells, and that mechanical disorganization of the cellular structure might well be the cause of the ensuing reactions. He thinks that the general symptoms are caused, as in bacterial infections, by substances derived from the injured cells of the host, and these would also account for the local inflammatory response.

The recent report⁵ on the isolation of a crystallized filtrable virus, the etiologic factor of mosaic disease of tobacco, is revolutionary in its implications and tends to throw doubt on the conception that poliomyelitis, smallpox and numerous other virus infections are due to living agents. The apparent evidence that a specific protein, which in itself is incapable of multiplying, may function as a disease germ when placed in "symbiosis" with normal cells may explain why the filtrable viruses cannot be cultivated on artificial mediums. In the course of this study, Vinson⁶ and his colleagues obtained colloidal crystals that were uniform in appearance and moderately infectious and retained their infectivity on recrystallization.

In the light of these studies on the filtrable viruses, it is of interest to consider present views as to the cause of postvaccinal encephalitis. The most reasonable hypotheses at present are the following: 1. The vaccine virus is the direct cause of postvaccinal encephalitis. 2. Vaccination induces activation of some other virus latent in the body. 3. The encephalitis is the clinical expression of a local allergic (anaphylactic) reaction of the central nervous system in which the virus acts as a sensitizing agent.

Several objections have been raised to the first theory. Encephalitis occurs in a relatively small proportion of the vaccinated persons (1/100,000 in Germany, 1/4,000 in Holland and 1/48,000 in England), whereas gener-

alization of the vaccine virus occurs regularly after vaccination. Thus, Herzberg⁷ studied 188 blood specimens and fifty-six spinal fluids from vaccinated persons and demonstrated the virus in the blood from three to ten days after vaccination, in the spinal fluid no vaccine virus was demonstrable even on days when the blood was positive. He found that in the course of normal vaccination the blood is free from vaccine virus by the tenth day. Moreover, no correlation has been observed between the virulence of the vaccine virus and the frequency of encephalitis. Most investigators have not seen any increase of the virus in the spinal fluid or brain of such patients. Eckstein² and his co-workers believe that postvaccinal encephalitis develops when the barrier between the blood and the spinal fluid is broken through. He further emphasizes the fact that no correlation has been observed between encephalitic complications and the severity of the vaccinal reaction, nor was there any correlation between the incidence of encephalitis and the number of vaccinations. Furthermore, it is not clear why the vaccine virus is so rarely found in the spinal fluid of patients suffering from postvaccinal encephalitis. Levaditi and his co-workers⁸ try to explain this by their concept of "autosterilization" in the central nervous system due to rapid death of the virus after its localization in the tissues. Doerr and Berger⁹ note that in generalized vaccinia there is a hematogenous metastasis of the virus into the skin. The content of these metastatic pustules is noninfectious, possibly owing to the formation of antibodies. These authors would explain in this way the "autosterilization" or death of the vaccine virus within the central nervous system. Bijl and Frenkel¹⁰ demonstrated that the brain of a child, dead of postvaccinal encephalitis, could kill vaccine virus *in vitro*. Finally, the view that this disease is due to the vaccine virus itself does not explain its frequent incidence in certain countries (Holland, England and Germany) and the very infrequent occurrence in other countries (Spain and the United States).

The second theory, the activation hypothesis, assumes that some heretofore latent infection is aroused by the vaccination. Until recently it was thought that the latent agent was the virus either of epidemic encephalitis or of poliomyelitis, but this has not been proved. Levaditi and Nicolau¹¹ studied the "activation" effect of vaccine virus by inoculating the nasal mucous membrane of the rabbit with herpes virus and simultaneously vaccinating the animals. The result was a typical herpetic encephalitis, which did not occur in the unvac-

cinated controls. Nevertheless, in human beings with encephalitis after vaccination it has been impossible to find any except the vaccine virus in the brain or spinal fluid. However, the proponents of the activation theory do not agree on the nature of the activated agent. Some say it is the herpes virus, others maintain it is the virus of epidemic encephalitis, and still others blame a virus as yet unknown. Thus far the facts do not warrant the acceptance of the "activation" theory as an explanation of postvaccinal encephalitis.

The third hypothesis considers the cause to be the inflammatory reaction in the central nervous system induced by the union of virus (antigen) and the specific antibodies. This reaction is thought to be similar to that occurring in the skin during generalized vaccinia and would depend on a considerable concentration of the virus in the brain.³ The definite incubation period of ten to twelve days would also tend to support this theory. In this connection Glanzmann¹² suggests that the central nervous system is sensitized and that there is lively antibody production, associated with local anaphylactic reactions.

It is well known that acute nonsuppurative encephalitis, similar clinically and pathologically to vaccinal encephalitis, may occur after measles, rubella, varicella, variola, mumps and pertussis. Freud¹³ in 1891, in his classic monograph on cerebral palsies in childhood, reported in detail cerebral complication after acute infectious diseases in childhood. He further noted that cerebral complications may occur after vaccination and cited previous reports of cases. Many of the infectious diseases of childhood are characterized by their dermal reactions (exanthems). Since the central nervous system is of ectodermal origin, it might be expected to react to some of these dermatotropic viruses.

As concerns prophylaxis, it is recommended by the English commission (1930) that vaccination be done during the first year of life, that one small scarification is sufficient, that revaccination be done at from 5 to 7 years and at from 14 to 17 years, and that routine follow-up examinations be carried out from fourteen to seventeen days after vaccination.

In the treatment of patients suffering from postvaccinal encephalitis the use of convalescent human serum or serum of persons successfully vaccinated has given gratifying results. The success of this treatment rather tends to indicate that the vaccine virus itself is the cause of the disease. However, the local and constitutional factors that determine the anomalous geographic distribution still remain to be explained.

At present, then, no agreement has been reached as to the etiology of postvaccinal encephalitis. This need not, however—indeed, certainly should not—interfere with the continued practice of smallpox vaccination.

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS EDUCATION PUBLIC HEALTH, ETC)

ARIZONA

Health Education Division Created—The Arizona State Health Department established a division of health education during October, in an effort to arouse a deeper interest in health problems throughout the state, according to *Public Health News*. The new department will cooperate with any community, school or club wishing to present a health program by furnishing health films.

ARKANSAS

Society News—At a meeting of the Pulaski County Medical Society, October 2, Dr Esmond R Long, Philadelphia spoke on tuberculosis —The recently organized Tri-County Medical Society (Yell Pope and Conway) was addressed, September 21, in Atkins by Drs Wells F Smith Little Rock, on fractures, and Henry E Mobley, Morrilton, on blood stream infections

CALIFORNIA

Births in Maternity Homes and Hospitals—In 1932, 50,280 births, or 64.4 per cent of the 78,108 births registered in California, occurred in maternity homes and hospitals, as compared with 62.2 per cent in 1931. Of the 50,280 births occurring in institutions, 11,322, or 22.5 per cent, were in county hospitals.

Society News — Byron Pitts district attorney for Los Angeles County spoke on legal medicine, and medicine and criminology before the Hollywood Academy of Medicine, October 19 — At a meeting of the Society for Neurology and Psychiatry in Los Angeles October 18 Dr Samuel D Inglisham, among others, spoke on 'Ruptured Aneurysm of the Internal Carotid' — Dr John V Barrow among others gave an illustrated lecture on "Clinical Amebiasis" before the Pacific Physiotherapy Association in Hollywood October 18 — Dr Walter C Alvarez, Rochester, Minn addressed the Alameda County Medical Association Oakland October 16, on abdominal pain

Clinical Departments Reorganized—Numerous changes made in a recent reorganization of the clinical departments of the College of Medical Evangelists, Los Angeles, include the following:

Dr. Charles C. Browning, emeritus professor of tuberculosis.
Dr. William A. George, emeritus professor of surgery.
Dr. Albert L. Hill, emeritus professor of pediatrics.
Dr. John A. Barrow, director of clinical teaching in the department of medicine, Los Angeles County General Hospital.
Dr. William H. Olds, appointed professor of clinical surgery and director of clinical teaching (department of surgery), Los Angeles County General Hospital.
Dr. Arthur B. Cecil, appointed professor and head of the department of urology.
Dr. Carl R. Howson, promoted to professor and head of the department of tuberculosis.
Dr. Cyril P. Courville, professor and head of the department of neurology.
Dr. William A. Hoyce, for many years professor of ophthalmology, now head of the department.
Dr. Robert F. Moody, appointed as professor and head of the department of pediatrics.
Dr. Walton L. Halverson, head of the department of communication diseases with the rank of a late professor.
Dr. Malcolm R. Hill, head of the department of pediatrics with the rank of associate professor.
Dr. Clifford I. Walker, professor of clinical ophthalmology.
Dr. James Hara, professor of clinical otolaryngology.
Dr. Owen H. Hume, professor of clinical otolaryngology.
Dr. Lawrence C. Grant, Jr., associate professor of pediatrics.
Dr. Joseph A. Latta, associate professor of pediatrics.
Dr. Thomas J. Zerk, associate professor of pediatrics.
Dr. Theodore S. Kimball, associate professor of pediatrics.
Dr. Fred J. Hume, associate professor of pediatrics.
Dr. Wendell A. Hume, associate professor of pediatrics.

Association News

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks

The American Medical Association broadcasts on Tuesday and Thursday mornings from 8:55 to 9 o'clock central standard time over Station WBBM (770 kilocycles or 380.4 meters).

The subjects for the week are as follows

November - Single Trouble

November 9 The Wrong Way Down

There is also a fifteen minute talk sponsored by the Association on Saturday morning, from 9:45 to 10 o'clock over Station WRLM.

The subject for the week is as follows:

11 Mar Dec

CONNECTICUT

Hospital News—The new \$250,000 Greenwich Municipal Hospital was dedicated recently, Drs Shirley W Wynne, health commissioner of New York City, Stanley H Osborn, Connecticut state health commissioner and Raymond D Fear, health officer of Stamford, were the speakers.

Semiannual Meetings—The Hartford County Medical Association held its one hundred and forty-first semiannual meeting at the Manchester Country Club, South Manchester, October 24. Speakers were Drs Amos E Friend Manchester, on 'The Nasal Sinuses in Relation to Eye Disorders', George L Tobey Jr Boston 'Nasal Sinusitis,' and Francis A Faught, Philadelphia 'Medical Economics the Philadelphia Recommendations'. At the one hundred and fiftieth semiannual meeting of the New Haven County Medical Association in Waterbury, October 26 the program was presented by Drs James J Hennessy Waterbury, on 'Bronchoscopy in General Practice', Milton I Little 'Treatment of Unilateral Cataract with Contact Glasses', George Blumer, New Haven, 'Diagnosis of Encephalitis', Stanley H Osborn Hartford state health commissioner 'X-Ray Survey of Children in a Search for Tuberculosis', and Herbert R Edwards New Haven 'The X-Ray Findings of Six Thousand Four Hundred School Children in New Haven'. Dr Howard W Haggard, New Haven, was the dinner speaker.

DELAWARE

Health at Wilmington—Telegraphic reports to the U S Department of Commerce from eighty-five cities with a total population of 37 million for the week ended October 21 indicated that the highest mortality rate (23.5) appeared for Wilmington and the rate for the group of cities as a whole 10.7. The mortality rate for Wilmington for the corresponding period last year was 16.7 and for the group of cities 10.5. The annual rate for eighty-five cities for the forty-two weeks of 1933 was 10.8 as compared with a rate of 11.1 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

FLORIDA

Cancer Campaign—The cancer control committee of the Florida Medical Association has announced a campaign of cancer education. In addition to the distribution of literature and medical meetings other publicity methods will be used to acquaint the public with the recognition of cancer. It is planned to divide the state into districts with a member of the committee assigned to each and speakers will be provided to clubs and organizations wishing to offer programs.

Society News—The Florida East Coast Medical Association met at the Miami Biltmore Hotel Coral Gables, October 27-28. The following program was presented:

Dr Ernest B Milam Jacksonville The Interrelation of Gastro Intestinal Pathology with That of Distant Organs and Systems

Dr Clayton E Royce Jacksonville The Function of the Laboratory in the Diagnosis of Gastro Intestinal Conditions

Dr Elliott M Hendricks Fort Lauderdale What the X Ray Can Do to Help in the Evaluation of Gastro Intestinal Conditions

Dr Giffert S Osmund Orlando Indigestion in the Older Child

Dr Leigh F Robinson Fort Lauderdale Indigestion Associated with Gynecologic and Obstetric Conditions

Dr James Knox Simpson Jacksonville The Attitude of the Surgeon Toward Indigestion

Dr Spencer A Folsom Orlando The Relation of Indigestion to Lesions in the Chest Heart and Blood Vessels

Dr Ralph N Greene Jacksonville Psycho-Neurologic Conditions and Indigestion

The speakers at the second day's session included the following physicians:

Lauchlin M Rozier West Palm Beach Endocrinology and Menstrual Disturbances

Lester L Whiddon Fort Pierce Pellagra and the Depression

Isaac M Hay Melbourne Chorio Epithelioma

Medical and surgical clinics were conducted. At the annual banquet and dance for the association and the Dade County Medical Society, Drs Edward Jelks Jacksonville and Gerard Raap Miami, respective presidents of the organizations, were the speakers.

IDAHO

New Board of Medical Examiners—On September 15 the governor appointed the following physicians to the Idaho Board of Medical Examiners:

Alexander Barclay Coeur d'Alene Robert L Nourse Boise.

William W Brothers Pocatello Hugh P Ross Nampa

Harry L Wilson Idaho Falls Bartholomew Chipman Grangeville

The appointments will expire Dec 31 1934

ILLINOIS

Dr Miller to Lecture on Anatomy of Lung—Dr William Snow Miller, emeritus professor of anatomy University of Wisconsin School of Medicine, Madison, opened a series of lectures at the Veterans Administration Facility, Hines, October 30, with a talk on 'The Air Spaces and Their Structure'. Other subjects discussed on subsequent days were 'The Vascular Supply of the Lung', 'The Lymphatics and Lymphoid Tissue' and 'Some Applications of the Above Subjects to Disease'.

Chicago

Society News—The Chicago Medical Society will be addressed November 8, by Drs Richard H Jaffe, Henry Schmitz and Arthur H Curtis on cancer of the cervix of the uterus. Federal medical relief for the indigent will be discussed before the society November 15, by Drs William C Woodward and Roscoe G Leland, directors respectively, Bureau of Legal Medicine and Legislation and Bureau of Medical Economics American Medical Association.—Wilbur Tweedy, PhD spoke before the Endocrinology Club October 25 on 'Present Status of the Parathyroid Glands'.—At a meeting of the Chicago Pediatric Society Dr Abraham B Schwartz Milwaukee among others discussed 'Home Versus Hospital Care of Sick Children'.—Dr Isaac A Abt will address the eighteenth annual meeting of the Institute of Medicine of Chicago December 5 on 'Treatment of Whooping Cough A Study in the Evolution of Therapeutics'.

INDIANA

Tuberculosis Hospital for Wayne County—The contract was let October 16 for the construction of a tuberculosis hospital in Wayne County to be finished by August 1934. The institution will be erected with \$100,000 provided by Mrs India Esteb and will be known as the Smith Esteb Tuberculosis Hospital. In 1916 Mrs Esteb with her late husband David deeded to the county 160 acres of land located eight miles south of Richmond on State Road number 27, with the agreement that the county was to construct a tuberculosis hospital. Although the plan was considered at various times nothing definite was done until the acceptance of the recent gift of Mrs Esteb.

Society News—At a meeting of the Greene County Medical Society in Linton, October 12, the speakers were Dr Percy E McCown and Larue D Carter Indianapolis, on 'Treatment of Prostatic Obstruction' and 'Cerebral Hemorrhage' respectively.—Speakers before the Eleventh Indiana Councilor District Medical Association in North Manchester, October 25 included Drs Newell C Gilbert, Chicago, on 'Angina and Coronary Thrombosis', Thomas D Allen Chicago, 'Buried Treasure in the Fundus Oculi' and Earl Palmer, Logansport 'Mental Disorders as Seen by the General Practitioner'. Dr Louis H Segar, Indianapolis, addressed the evening session on 'Facts and Follies in Medicine'.—The Wayne-Union Counties Medical Society was addressed at Richmond October 12 by Dr Edward B Markey, Dayton, Ohio 'Treatment of Incomplete Abortions'. Dr Harry P Ross, Richmond, spoke on the Indiana plan as related to the child welfare department.—Dr Jacob P Greenhill, Chicago, discussed recent advances in obstetrics and gynecology before the LaPorte County Medical Society in Michigan City October 19.—The Hendricks County Medical Society heard Dr Rollin H Moser, Indianapolis talk on gastric ulcers, September 22.—Dr Elihu P Easley New Albany discussed the trend of the practice of medicine before the Floyd County Medical Society, New Albany September 8.—At a meeting of the Ripley County Medical Society Osgood October 11 Dr James C Carter, Indianapolis, spoke on infant feeding.—Dr Jay A Myers Minneapolis spoke before the Muncie Academy of Medicine Muncie, October 10, on 'Childhood Tuberculosis and Its Prevention in Schools'.—At a meeting of the Whitley County Medical Society at Blue Lake, October 10 Dr Ernest R Carlo Fort Wayne discussed children's diseases.—Dr Alois L Ziliak Princeton discussed cancer before the Gibson County Medical Society in Princeton, October 9.

IOWA

Graduate Courses—The medical societies of Calhoun, Dallas Guthrie, Carroll and Greene counties recently formed a graduate study club at Jefferson. Members of the faculty of the University of Iowa College of Medicine Iowa City are presenting courses which opened September 26 on internal medicine pediatrics and obstetrics.

MARYLAND

Dr Castiglioni Gives Noguchi Lectures—Dr Arturo Castiglioni, professor of the history of medicine University of Padua Italy, gave the third course of lectures under the Hideyo Noguchi Lectureship of Johns Hopkins University School of Medicine. The theme of the lectures was "The Renaissance of Medicine in Italy," and following are the individual titles:

October 23 The Dawn of Renaissance in the Life Art and Science of Italy—The Thought of Leonardo

October 25 The Flowering of Medical Studies at the Italian Universities from Herenclario to Celsus

October 27 The Legacy of Scientific Renaissance and the Main Currents of Medical Thought from Fracastoro to Galileo

In 1929, Dr Emanuel Libman, New York, gave \$10,000 to establish the lectureship in honor of Dr Noguchi.

Gastro-Enteritis Following a Picnic—An outbreak of gastro enteritis among persons who attended a picnic at Fairview Beach, Anne Arundel County in July, has been studied by the state health department, the Baltimore City and the Anne Arundel county health departments. Sixty-nine cases were found among 122 persons interviewed, out of a group of 167 who dined at the Fairview Beach Hotel. The majority of patients reported the onset of their illness within five hours after an evening supper. Some cases required hospitalization. No deaths occurred. The immediate source of the outbreak was not determined. Recommendations made by the county health department suggest that the general sanitary condition of the resort was in need of improvement. These recommendations included:

The abandonment of a dug well.
Provision of toilet facilities for persons who work and sleep in the hotel.

More efficient refrigeration for food storage.
Improved sanitation in the kitchen including repair of screens and better care of silver and utensils.
Examination of food handlers before the opening of the 1934 season.

A somewhat similar outbreak occurred at the same resort, July 20-25 1932.

MASSACHUSETTS

Society News—Dr Eugene H. Pool, New York, addressed the New England Medical Society, Boston, October 19 on "Chronic Duodenal Stasis."—At a meeting of the New England Physical Therapy Society in Boston, October 18, Dr William H. Watters discussed ultraviolet light.—The Middlesex South District Medical Society heard "Function and Workings of the Workmen's Compensation Law" discussed by Joseph A. Parks, chairman of the industrial accident board, and Drs. Francis D. Donoghue, Boston, and Charles E. Mongan, Somerville in Cambridge, October 25.—The annual meeting of the Massachusetts Psychiatric Society was addressed by Dr. Eugene Kahn, New Haven, Conn. on "Organic Drivenness—A Brain-Stein Syndrome and an Experience."—Allan Winter, Rowe, Ph.D., Boston, among others, addressed the New England Roentgen Ray Society, October 20, on "Structural Relationships in Abnormal Individuals."

NEBRASKA

Society News—At the annual meeting of the Seventh District Medical Society in Fairbury, October 19, speakers were Drs. James M. Willis, McCook, on "Personal Experience with Chemical Hysterectomy," Rollin Russell, Best, Omaha, "Diagnosis and Management of Rectal and Colon Lesions," Roy W. Fouts, Omaha, "What May Be Expected from the X-Ray as an Aid in Diagnosis," and Claude A. Selby, North Platte, "Medical Economics." Dr. Adolph Sachs, Omaha, president of the Nebraska State Medical Association, delivered an address on "The Laboratory and the Doctor" at a dinner given by the Jefferson County Medical Society.

NEW YORK

Programs for Graduate Instruction—Courses of instruction for practicing physicians are being conducted in four counties under the auspices of the committee on public health and medical education of the Medical Society of the State of New York. The Columbia County Medical Society is having a course on dermatology and syphilology in which the lectures are given by Drs. George M. McKee, Fred Wise, Henry D. Niles, George M. Lewis, Ithaca, W. Abramowitz, Anthony C. Cipriano, Marion B. Sulzberger, and Isadore Rosen, all of New York. In Monroe County the course deals with infections with the following speakers: Drs. Frank L. Meloney, Franklin M. Hanger, Jr., Hugh A. Hutchins, Clayton Murray, and Benjamin P. Watson. A course on gastro-enterology is being given at the Hamilton County Medical Society at Port Jervis by Drs. Albert F. L. Ayres, John P. D'Alella, and

Frederick Schroeder, Jr. A course in physical therapy by Dr. Richard Kovacs, New York, for the Niagara County Medical Society was noted in THE JOURNAL, October 28, p. 1400.

New York City

Special Lectures—Dr. Russell L. Cecil, professor of internal medicine, New York Polytechnic Medical School and Hospital, has begun a series of special lectures at the school, Wednesday afternoons. Subjects of the lectures which began, October 18 and will be given monthly till April are: encephalitis, typhoid, infectious endocarditis, influenza and the common cold, lobar pneumonia, rheumatic fever, arthritis.—A series of ten lectures on cultural medicine have been begun at New York Homeopathic Medical College and Flower Hospital. Among future lecturers will be Drs. George G. Ornstein on the history of tuberculosis, William Francis Honan, evolution of modern surgery, William H. Dieffenbach, economics of medicine, and Walter Gray Crump, the art as compared with the science of medicine. The lectures are being given Friday afternoons.

Society News—The first Friday afternoon lecture of the season at the New York Academy of Medicine was delivered November 3 by Dr. Charles Gordon Heyd on "The Differential Diagnosis and Early Treatment in Acute Abdominal Conditions." The second will be presented by Dr. Robert L. Dickinson, November 10, on "The Doctor as Marriage Counselor."—Dr. Milton C. Wintermiz, New Haven, Conn., addressed the First District Dental Society of the State of New York, October 2, at the New York Academy of Medicine on "The Study of Teeth in Relation to Medical Education." The address was followed by a round table conference led by Drs. Anthony Bassler, Russell L. Cecil, John H. Dunnington, Samuel J. Kopetzky, Bernard S. Oppenheimer, and Harmon Smith.—A symposium on "Disruption of Abdominal Wounds" will be presented at the meeting of the New York Surgical Society, November 8, by Drs. Frank L. Meloney, Ralph Colp, William Crawford White, Roderick V. Grace, and Charles Gordon Heyd.—Dr. Jacques W. Malinik was reelected president of the Society of Plastic and Reconstructive Surgery at the annual meeting, October 18. Drs. Fred H. Albee and John M. Wheeler were elected vice presidents and Dr. Arthur Palmer, secretary.

OHIO

Hospital News—Mr. Charles E. Findlay, superintendent of the Springfield City Hospital, has resigned to become superintendent of the Butterworth Hospital, Grand Rapids, Mich.—The John Lowman Memorial Pavilion for tuberculosis was dedicated at the Cleveland City Hospital, September 30. The new hospital has a capacity of 350 beds. Dr. Raymond C. McKay is medical director.

Faculty Changes at Cincinnati—Recent changes in the faculty at the University of Cincinnati College of Medicine include:

APPOINTMENTS

Dr. Lee Foshay, associate professor of research bacteriology.
Dr. Josef Warkany, assistant professor of pediatrics.
Dr. Louis G. Hermann, assistant professor in the department of surgery.

PROMOTIONS

Dr. Frank E. Stevenson to associate professor of pediatrics.
Dr. Waldo E. Nelson to assistant professor of pediatrics.
Dr. Johnson McGuire to assistant professor of medicine.
Dr. Nathan Chandler Foot resigned as professor of pathology to go to Cornell University Medical Center, New York.

Society News—Dr. Clarence E. Hufford, Toledo, was elected president of the Northwestern Ohio Medical Association at the annual meeting in Tiffin, October 3. Next year's meeting will be held in Toledo.—Dr. George J. Heer, Columbus, addressed the Athens County Medical Society, October 2, at Nelsonville, on surgical diagnosis.—Dr. Gerald S. Shibley, Cleveland, gave an address on communicable diseases before the Portage County Medical Society, Ravenna, October 4.—Drs. Howard L. Stitt and Charles L. Wooding, Cincinnati, addressed the Washington County Medical Society, Marietta, October 11, on bronchial lavage.—Dr. Irvin J. Lachon, Quaker City, addressed the Guernsey County Medical Society, Cambridge, October 5, on anemias.—A symposium on intestinal obstruction was presented before the Montgomery County Medical Society, Dayton, October 20, by Drs. Raymond I. Holmston, Homer D. Cassel, Robert D. Hostetter, and Robert C. Austin.—Dr. Wingate Todd, Cleveland, addressed the Toledo Academy of Medicine, October 6, on "The Developmental Health Examination for Children."

PENNSYLVANIA

Personal—Dr Anson J Singer, East Stroudsburg, was guest of honor at a luncheon attended by physicians from Monroe, Lackawanna and Luzerne counties at Buck Hill Falls recently in honor of his seventy-fifth birthday and his completion of fifty years of practice—Dr Irvin D Metzger, Pittsburgh was reelected chairman of the state board of medical education and licensure and Mr W M Denison, deputy state superintendent of public instruction, was elected secretary

Philadelphia

First Series of Seminars—The annual series of graduate seminars under the auspices of the Philadelphia County Medical Society on Friday afternoons began November 3. The first group of five lectures is devoted to disorders of the kidney. At the first meeting Drs John A Kolmer and Leonard G Rowntree spoke on 'Classification of Disorders of the Kidney Characterized by Symptoms of Bright's Disease' and 'The Laboratory and Kidney Disorders Tests of Renal Function,' respectively. Coming lectures will be as follows

November 10 Dr Arthur M Fishberg Glomerulonephritis
November 17 Dr Edward Weiss Hypertension and Vascular Disease in Relation to Kidney Disorders and Dr Walter I Lillie The Value of Background Study in Hypertension and Kidney Disorders
November 24 Dr Abraham Cantarow Nephroses and Dr Harold W Jones Treatment of Kidney Disorders

The meeting, December 1, will be a round table conference

Group Medical Service Plan Subject to Insurance Laws—The attorney general of Pennsylvania has recently ruled that a group known as the Philadelphia Life and Health Extension Service is performing the kind of business usually performed by an insurance company and is therefore subject to the insurance laws of the state. The ruling was handed down in response to a request from the commission on medical economics of the Philadelphia County Medical Society. Under the plan proposed by this organization medical care and attention is furnished for all illnesses and minor injuries (except those that are compensable) which can be treated in its offices for \$1.50 a year. It agrees "to make complete or partial medical examinations whenever desired or required and to make analytical reports on same if desired." The attorney general declared that in his opinion this is insurance service and is being performed contrary to law. This is true whether it is the general public or members who purchase it and whether what they pay be considered dues or a premium," he concluded

SOUTH CAROLINA

Society News—The annual meeting of the Fourth District Medical Society was held in Spartanburg, September 26, with Drs William Egleston, Hartsville, president-elect of the state society, and Edgar A Hines, Seneca, as guests. Among speakers on the scientific program were Drs Thomas R Gaines, Anderson, on tracheotomy in laryngeal diphtheria, Lawrence H McCalla, Greenville, indications for surgery of the thyroid gland, and Job H Crooks, Greenville, dermatology in general practice

SOUTH DAKOTA

Personal—Dr Edwin T Ramsey, Clark, was elected president of the South Dakota Health Officers' Association at the annual meeting in Huron, October 4—Dr William F Keller, Sioux Falls, has been appointed state prison physician succeeding Dr Herbert J Day, who plans to return to private practice

TEXAS

Society News—The annual meeting of the Fourth District Medical Society was held in Brownwood, October 2-3. Speakers included Drs Charles S Venable, San Antonio on 'Treatment of Osteomyelitis with Surgical Maggots,' Arthur C Scott, Temple, 'Modern Management of Gallbladder Disease,' William Porter Brown, Fort Worth 'Uses and Limitations of X-Rays and Radium in Dermatology,' and Wilson D Anderson, Sanatorium, 'Phrenic Nerve Resection in Treatment of Pulmonary Tuberculosis.' Dr Abner A Ross, Lockhart, president Texas State Medical Association, was the speaker at the annual banquet

Graduate Assembly in Houston—The second Post Graduate Medical Assembly of South Texas sponsored by the South Texas District Medical Association, will be held in Houston, November 21-24. Mornings and evenings will be devoted to general sessions and afternoons to sectional meetings. There will also be round table luncheon discussions led

by guest speakers. Twenty-six guests will be present, among whom are the following, with their subjects for general sessions

Dr Isaac A Abt, Chicago, Management of the Baby in the First Three Months of Life
Dr Willis C Campbell, Memphis, Tenn, Practical Application of Orthopedic Principles
Dr John T Erdmann, New York, Tumors of the Breast
Dr Louis Hamman, Baltimore, Diagnosis of Obscure Fever
Dr John W Harris, Madison, Wis., Fundamental Problems of Clinical Obstetrics
Dr Allen K Krause, Tucson, Ariz, Tuberculosis and the General Practitioner
Dr Francisco de P Miranda, Mexico City, Ovarian Disturbances from the Standpoint of Endocrinology
Dr Bernard H Nichols, Cleveland, Roentgenologic Diagnosis of Lesions Causing Right Upper Abdominal Pain
Dr Leonard G Rowntree, Philadelphia, Recent Advances in Endocrinology
Dr Richard L Sutton, Kansas City, Mo, Diagnosis and Treatment of Cancer of the Skin
Dr Hugh H Young, Baltimore, What Operations Should Be Chosen as Best Suited for the Various Pathological Conditions Present in Prostatic Obstruction?
Dr John H Musser, New Orleans, Comparison Between Syphilitic Arteriosclerotic and Rheumatic Heart Disease

The southwestern branch of the American Urological Association will meet in Houston concurrently with the assembly

VERMONT

Personal—Dr Frank E Farmer, St. Johnsbury, was elected president of the Vermont Medico-Dental Golf Association at its annual meeting in Rutland. William R Pond, DDS, Rutland, won the tournament with a low net score of 69

Society News—Dr Grant P Pennoyer, New York, addressed the Rutland County Medical and Surgical Society, October 17, on varicose veins. In the afternoon Dr Pennoyer conducted a clinic showing the injection treatment at Rutland Hospital

GENERAL

Grants Available for Research—The Committee on Scientific Research of the American Medical Association invites applications for grants in aid of research on problems bearing on the clinical aspects of medicine and surgery. Inquiries may be addressed to the committee at 535 North Dearborn Street, Chicago

Conference on Dermatology—Under the auspices of the Washington-Baltimore Dermatological Society, the dermatologic societies of Washington, Baltimore, Philadelphia, New York, New England and Canada will convene in Washington, D C, November 18 with headquarters at the Mayflower Hotel. The program will include the presentation of a clinic by Georgetown University School of Medicine. Dr Charles Lee McCarthy is general chairman

Fellowship Available—Application for the annual fellowship of the Herbert Celler Fellowship Fund will be accepted until December 1 by the secretary, Dr Benjamin Eliasoph, 941 Park Avenue, New York. Candidates should submit personal records, lists of publications, if any, outline of proposed study and suitable recommendations. This fund was established several years ago in memory of the late Dr Celler, who was associate attending physician at Mount Sinai Hospital, New York

Decrease in Automobile Fatalities Last Year—Deaths from all types of motor vehicle accidents in the registration area (except Utah) decreased from 32,429 in 1931 to 28,240 in 1932, according to the U S Department of Commerce. In Oklahoma and Arizona the rates increased slightly, but in both states the rates were less than those for 1930. In the District of Columbia the rate increased from 29.3 in 1930 and 33.6 in 1931 to 39.1 in 1932. Nevada had the highest rate in 1932, 64.5, and North Dakota the lowest, 8.6. The latter was only a little more than half the rate for 1931. In the total number of all deaths from motor vehicle accidents in 1932 there were 1,462 caused by collisions with railroad trains, 302 by collisions with street cars, and 241 by motorcycle accidents. In each of these classes there was a considerable decrease from the preceding two years

Society News—Dr Eugene L Bishop, Nashville, state health officer of Tennessee, was chosen president-elect of the American Public Health Association and Dr Haven Emerson, New York, was installed as president at the annual meeting in Indianapolis, October 11. Vice presidents elected were Drs William F King, Indianapolis, John G Fitzgerald, Toronto, and Walter H Brown, Palo Alto, Calif. The 1934 session will be held in Pasadena, Calif.—Dr Willard R Cooke, Galveston, Texas, was chosen president-elect of the Central

Oct 14, 1933

A National Memorial to Sir Robert Jones

In a joint letter to the *Times* Lord Moynihan Lord Dawson (president of the Royal College of Physicians), Sir H J Waring (president of the Royal College of Surgeons), Lord Derby and others report the steps taken for a national memorial to Sir Robert Jones. They point out that the claim of Robert Jones for universal recognition is based on fifty years of service, devoted at first to the cure, and later to the prevention, of those deformities which for centuries have meant suffering and weakness to a large proportion of the human race. Before he was born, a multitude of children grew up in helplessness. When he died his orthopedic principles and the methods he had introduced were practiced throughout the world. During the war his name became a household word. He carried to thousands of disabled soldiers the same message of hope and recovery as to the crippled child. In salvage of life as in restoration of limb he revealed to a great multitude of fellow surgeons principles of treatment which are now the common heritage of civilization. A primary object of the national memorial is to perpetuate his work so that his teaching shall never be forgotten or misinterpreted, and so that the branch of surgery of which he was the master shall continue to be taught according to his ideals. To this end it is proposed to found a Robert Jones lectureship in the Royal College of Surgeons and to institute a traveling research fellowship in orthopedics, to be awarded alternately by the Royal College of Surgeons and by the University of Liverpool (in which city Jones practiced the greater part of his life).

It is also desired that this national memorial shall bear testimony to the constructive idealism in which Jones demonstrated the efficacy of his mission, particularly in regard to crippled children, not only as to their complete cure but as to the prevention of deformities. Throughout Great Britain are hospitals, after care clinics and training centers raised under his direct guidance. To unite these two principles of scholarship and social service is to recognize in our time the universal influence of Robert Jones on the welfare of our people.

Should the total sum subscribed equal or exceed the hopes entertained after provision for the main objects of the memorial, any balance remaining will be deposited with trustees for financial aid to orthopedic centers which need it, and will be denominated "The Robert Jones National Trust Fund."

Is Health Insurance Becoming a Dole?

Sir Henry Brackenbury in his presidential address to the Section of Preventive Medicine at the recent annual meeting of the British Medical Association asked the question Is health insurance becoming a dole? He found that people were more concerned with the doling out to them of small sums week by week or month by month, than with medical service. He referred to the fact that owing to unemployment a large number of the insured were passing out of the scheme. His remedy was a further development of medical socialism. So called health insurance is to a greater extent not an insurance system at all but a subsidy to which the state and the employer make a larger contribution than the insured person. Once on the slippery slope of socialism the tendency is always downward and more and more is demanded from the taxpayer. This was illustrated at the twenty-first annual meeting of the National Association of Insurance Committees when it was stated that the council visited the ministry of health to discuss the position of insured persons who would cease to be entitled to medical

Association of Obstetricians and Gynecologists and Dr Everett D Plass, Iowa City, was installed as president at the recent annual meeting in Milwaukee. Dr William A Coventry, Duluth, Minn, was elected vice president and Dr Ralph A Reis, Chicago, reelected secretary. The 1934 session will be held in New Orleans. The National Association for Nursery Education held its annual conference in Toronto, October 26-28. Among discussion groups was one on the physical health of the preschool child in which the following took part: Dr Charles A Aldrich, Winnetka, Ill. Miss Mary Sweeny, Detroit. Helen Monsch, Ithaca, N Y. Dorothy Van Alstyne, Winnetka, Josephine Kenyon, New York, and John R. Murlin, Ph.D., Rochester, N Y. Dr Robert A Fraser, New York, was elected president of the Association of Life Insurance Medical Directors of America at the annual meeting in Toronto, Ont., October 12-13. Among speakers at the meeting were Drs Harold E B Pardee, New York, on "Theory and Practical Application of the Electrocardiogram in Life Insurance", Israel M Rabinowitch, Montreal, interpretation of blood sugar time curves in diagnosis of diabetes mellitus, Levefys F Barker, Baltimore, Disposition to Nervous or Mental Disease as a Consideration in the Selection of Insurance Risks, and Louis I Dublin Ph.D., and Herbert Marks, New York, "Mortality of Risks with Asthma."

PHILIPPINE ISLANDS

Society News—The Manila Medical Society was addressed recently by Drs Antonio G Sison and Liborio Gomez on rheumatic heart diseases in Filipinos, Dr Vivencio C Alcantara gave a demonstration in the use of bronchoscopic instruments. Dr James A Doull, Cleveland, who is spending some months in the islands under the auspices of the Leonard Wood Memorial Foundation, among others, spoke on "What We Get Out of the Medical Society" before the Cebu Medical Society, recently.

FOREIGN

Personal—Dr Henry P Gilding, London, has been appointed to succeed Dr Ivan de Burgh Daly as professor of physiology at the University of Birmingham. Dr Daly recently became professor of physiology at the University of Edinburgh in succession to Sir Edward Albert Sharpey Schäfer. Dr William Stewart Duke-Elder, ophthalmic surgeon to St George's Hospital, London, recently received the Nettleship gold medal and prize awarded by the Ophthalmological Society of the United Kingdom for the most valuable contribution to ophthalmology during the past three years.

Recent Changes Among Teachers in Germany—Prof Schwartz, Ph.D. of Frankfurt-am-Main has been called to Stambul in the capacity of director of the Institute of Pathology there. Dr Werner Lipschitz formerly professor of pharmacology at the University of Frankfurt-am-Main, has been dismissed from public service. The following in Frankfurt-am-Main have been deprived of the right to teach: Asst Prof Dr Joseph Igersheimer Altmann (skin and venereal diseases), Dr Hugo Braun (hygiene and bacteriology), Dr Edgar Goldschmidt (general pathology and anatomopathology), Dr Marcel Traugott (obstetrics and gynecology), Dr Raphael Weichbrodt (psychiatry and neurology), San-Rat Dr Wilhelm Hanauer (social medicine), Dr Richard Koch (history of medicine), Dr Walter Lehmann (surgery), Dr Joseph Berberich (otorhinolaryngology), Dr Franz Herrmann (dermatology and syphilology), Dr Emmy Kheneberger (bacteriology), Dr Ernst Herz (psychiatry and neurology), and Dr Ernst Metzger (ophthalmology).

Deaths in Other Countries

Albert Calmette, co-discoverer with Guérin of BCG anti-tuberculosis vaccine, honorary professor of bacteriology and hygiene, University of Lille and assistant director of the Pasteur Institute since 1927 died in Paris October 29 of an abdominal ailment aged 70. Sir Arthur Mayo Robson, surgeon, teacher and writer knighted for his activities in Egypt and Gallipoli during the World War died in London October 12 aged 80. Donald John Armour, consulting surgeon, National Hospital for Nervous Diseases and formerly president of the Medical Society of London, West London Medico-Surgical Society, the Neurological Section of the Royal Society of Medicine and of the Association of British Neurological Surgeons died suddenly October 23. Gaston Melo Mexico D F head of the Mexican Department of Health died October 26 of heart disease following an operation for appendicitis.

benefit at the end of the year because of their failure to contribute in consequence of unemployment. Their suggestion, of course, was more money from the taxpayer. They asserted that the original act was created to prevent sickness and not merely to pay for sickness. They said that the government "agreed to make a contribution, but did not hesitate later to break its contract and thereby made it impossible for certain organizations to provide what was needed. The equivalent of \$100,000,000 to \$150,000,000 having been taken from insurance funds, was it unreasonable to ask for \$150,000 or \$200,000 to prevent sickness?" This was a flagrant misrepresentation. As a matter of fact, there was no "contract" such as is postulated. When the so-called insurance scheme was established by the most prodigal politician that ever spent the taxpayer's money, the demand for still more from the state soon arose, because expenditure, as is always the tendency with socialistic finance, was in excess, and this was granted. At a later date, when economy became necessary, because of socialistic prodigality, some of the additional subsidy was withdrawn. There was no "contract" in the matter. A resolution was moved that "the only course to preserve these persons in medical benefit is to press for a government grant." A member moved an amendment, expressing willingness to cooperate on any practicable scheme for providing medical treatment for unemployed persons but refraining from making any representations in the matter. He asked why the insurance principle which was inviolate in one sphere should not be so in another? Why should the state scheme be treated differently from other forms of insurance? The amendment was defeated by a vote of 226 to 78.

England Repudiates the Aryan Doctrine

A frank and authoritative announcement of the British government's attitude toward minorities in general, and the Jewish minority in particular, was made by Mr. Ormsby-Gore, the British delegate at a discussion of the League of Nations in Geneva. It arose out of a speech by the German delegate Herr von Keller complaining that the rights of German minorities in other countries were not sufficiently recognized and claiming that they were attached to Germany by "an unbreakable link." "We reject absolutely," said Mr. Ormsby-Gore, "this conception put forward by the German delegate with regard to the racial homogeneity of political units and states." Turning to the German Aryan doctrine the British delegate said that it could not apply to the British Empire, in which it had always been a cardinal principle that no person could be debarred from holding any post, in the words of Queen Victoria in her proclamation as Empress of India, "by reason of race, color or creed." The fundamental and only thing that held the British Empire together was equality of status and freedom. The Empire did not conceive itself in terms of racial solidarity but in terms of the free association of free peoples, encouraged to develop their national consciousness within the greater unity. He would not have referred to the question of the Jews had not the German delegate queried whether they ought to be regarded as a minority in any country. "If in connection with the Germans in Czechoslovakia and other neighboring countries he emphasizes the ethnical basis, he cannot have it both ways. If the racialism of the Aryan German be admitted that of the Jews must also be admitted. I say definitely that there is among the Jews a sense of their historic continuity throughout their dispersal and that they form a racial minority which deserves the same treatment everywhere as all other minorities in all countries, above all, equal rights of citizenship. Wherever they have been well treated they have been the most loyal and helpful members of the nation."

The attempt to pervert anthropology for political ends is not new but here it is audacious, for the persecution of all persons of pacifist or liberal views, Jew or Gentile, shows that the

racial reason is only a cloak for the real motive. A different perversion of anthropology has been furnished by the Nazi Reich commissar of justice, who claims that "from the Germanic race have sprung the highest achievements of man." This has led a well known anatomist and anthropologist, Prof. Le Gros Clark, to point out in the *Times* that there is no such thing as 'a Germanic race' but only a mixture of races. He quotes another anatomist and anthropologist, Prof. T. C. Parsons, who has shown that since the sixth century the broad headed Alpine race has been steadily supplanting the Nordic in every part of Germany. But what of the superiority? It is curious that the commissar should make this claim in the face of the fact that the Nazis complain of the greater success of the Jews in the professions. It is only since their expulsion that we have realized in England the extent to which Germany was indebted to them for her most eminent men.

A Diabetic Association

Mr. H. G. Wells, the writer, invited "his fellow diabetics" to form an association to help King's College Hospital (which has a special clinic for diabetes under the control of Dr. H. D. Lawrence) in gratitude for what the modern treatment of diabetes had done for them. Mr. Wells has now obtained \$4,000 for the hospital and is proceeding with the formation of his diabetic association. For this purpose, a number of those who responded to his appeal will dine with him at a special table at the festival dinner of King's College Hospital.

Procaine Hydrochloride in the Treatment of Rheumatism

The medical profession is indebted to Professor Leriche of Strasbourg for a method of treatment for sprains and mild luxations, which consists in injecting a cubic centimeter of a solution of procaine hydrochloride (1:1,000) at the level of the painful areas. The anesthesia thus secured suppresses the reflex that supports the contracture of the ligaments. A person with a sprain thus treated can walk immediately after the injection. Schulmann and Benassy have applied this method to persons with rheumatic joint pains with complete success. Even in cases of chronic arthritis, the injection of procaine at the insertions of the ligaments and the articular tendons brought about quickly not only relief from the pain but also restoration of the movements. The procedure has more chance of success when the functional disorders are more significant and the articular lesions are more discrete. To explain these results, both Schulmann and Leriche assume the existence of a short reflex in which the area of excitation is located in the insertion of the ligament. This communication to the *Société des médecins des hôpitaux de Paris* brought forth an observation from P. Weill, who stated that he had secured the same results by the periarticular injection of 0.20 Gm. of cocaine. He obtained in this manner some startling results, the patients recovering immediately the normal amplitude of movements. This method constitutes an interesting differential procedure in the treatment of genuine arthritis and periarthritis, the former being but slightly influenced by the anesthetic.

Diagnosis of Tuberculosis by Examination of the Gastric Contents

Mr. Saye presented recently before the *Société de biologie* work performed in collaboration with R. Shelton and J. Domech Alsina on the early diagnosis of tuberculosis in children. The method consists in the inoculation of the stomach contents into the guinea-pig. Armand-Delille and Vibert had already used this procedure in confirming the diagnosis of pulmonary

tuberculosis It is today established beyond doubt that tuberculous infection originates in the digestive tract and not in the lungs Examination of the stomach contents enables the physician to discover the first stage of the infection before there is any generalization In Mr Saye's investigations, inoculation of guinea pigs with gastric contents derived from 146 children whose ages ranged from a few days to 10 years, and only 107 of whom were avowedly tuberculous, proved positive in forty-four cases or 41 per cent In one child, the result was positive two weeks before the appearance of the allergy In nineteen of the children, only benign tuberculous types without apparent signs were involved These observations show that it is wrong to base tuberculosis prophylaxis solely on the more evident dangers of contagion Mr Saye concludes that one cannot hope to eradicate tuberculosis in children other than by introducing early vaccination with the BCG vaccine At this point, Mr Sergeant remarked that it is more simple to search for bacilli in the stools, provided cases of tuberculous enteritis are excluded Mr Saye however, contended that examination of the gastric contents and inoculation in guinea-pigs constitute an easier procedure Mr Rist added that this method is applicable also to adults (who are much more numerous than is supposed) who swallow their sputum Mr Saye sees, furthermore, in the absence of bacilli in the stomach of the person who has been unquestionably tuberculous an interesting evidence of recovery

No Retrenchment in Physicians' Work in Hospitals

Hospital administrators are no doubt convinced that they have for some time reached the limit in economizing and hence they have refrained from further retrenchments Little attention, however, appears to have been given to the fact that the hospital personnel, and particularly the physicians, has been burdened almost beyond endurance Retrenchment has necessarily been associated with the danger of a lowering of standards It has been almost unavoidable that, owing to the increase in the large amount of paper work and the abandonment of many measures more or less important in department administration in the laboratories in the radiologic department and elsewhere, the real personal work with the patient has been cut short In this connection special significance is attached to an annual report of the surgical department of the hospital 'Bergmannsheil' in Bochum, for the year 1931, which was recently rendered by the chief physician, Professor Magnus He says that it is impossible to give, by means of statistics a complete picture of medical or surgical activities Statistics will, however, furnish a partial basis for an inquiry as to whether there has been a proper distribution of labor Comparing clinical activity it will be observed for example, that in 1926 eight assistant physicians made, on an average 607 examinations each and in 1931 nine assistant physicians averaged 1220 examinations With respect to the case histories the proportion was 463:524 As regards case histories attention should be called to the fact that they do not lend themselves to comparisons because as time goes on they tend to become more detailed and to be written with a view to future use as a basis for the estimation of degrees of disability In 1931 463 letters per assistant physician were written to the physicians who referred the patients and the total number of papers and documents written or filled out per assistant physician annually averages now 2147 as against 1131 five years ago The number of operations performed by each assistant is now 549 as compared with 292 and the number of roentgenograms per assistant is 2026 as against

1,817 These figures show clearly how the assistant physicians are overwhelmed with reports and paper work in general To expedite this work, the hospital now has six secretaries, as compared with four in 1926 Each secretary gets out, on an average 3,232 documents, as against 2,262 formerly These figures hold good today and must be taken as a serious sign of the times

Economical Management of Hospital Kitchens

The Gutachterausschuss für das öffentliche Krankenhauswesen has published 'Criteria for an Economical Management of Hospital Kitchens' The details of a diet are determined by the prescriptions of physicians, the local customs of the population and the organization of the commissary department of the hospital concerned Every hospital must have a system of diets There must be a permanent committee on cuisine and the art of preparing menus for a dozen or more regimens must be thoroughly understood Permanent supervision must be exercised to prevent the more expensive dietary forms being used unnecessarily To determine whether the food allowance is too large it is more important to inspect the amount and nature of the food left on the plates than it is to compute the calorie content Serving an undue number of side dishes should be avoided A single dietary form must not be made too individualistic The daily money allowance serves as the basis for the selection of the foods for the various classes of service and the different types of personnel The expenditures for food are influenced to a great extent by the quality of the food and the skill of the buyer It is not always necessary to select the first quality An administrative official is usually a better buyer than the head cook Economies are possible through careful judgment in buying for example, restriction in the use of white bread in favor of rye bread when that is possible As a minimum ration often 200 Gm of rye bread daily will suffice, except on days when a cold supper is served The use of coffee substitutes in place of genuine coffee, which should be served as a medicine and only on medical prescription, is good economy Butter is needed in the kitchen only for the preparation of the diet for patients with stomach ulcers and for a few other diets and can ordinarily be replaced by a good quality of vegetable fat Forced feeding and the diet for patients with diabetes are exceptions For the general diet the best substitute for butter is the best grade of vegetable oil 'butter' its low vitamin content need cause no anxiety provided the diet has the proper components The expensive diet of tuberculous patients can be cheapened without harm by fixing the butter allowance at 50 Gm and giving the remainder of the fat requirement in the form of lard or good vegetable oil 'butter' Only the best quality of meats should be purchased whether they are procured from the butcher or whether the hospital does its own slaughtering The following allowances of raw meat (with bones) will often suffice beef 120 Gm, pork 100 Gm, veal, 125 Gm, fish 250 Gm sausage 100 Gm A large institution will find it an advantage to establish a meat market of its own In the case of peas beans and lentils, there is a wide range of prices a good average quality will usually suffice There are many different qualities of rice an average quality is sufficient Expensive olive oil can be replaced by sesame oil, peanut oil or soy bean oil The substitution of glucose for sugar is not recommended without medical approval

Neuropsychiatric Departments in General Hospitals

The question of the need of neuropsychiatric departments in general hospitals is being discussed and both internists and psychiatrists are claiming this field for themselves This question was discussed at the recent Congress of German Psychiatrists

According to the Breslau psychiatrist Prof. Johannes Lange, there are only about twenty special departments of this kind, and they are inadequate to supply the need. About 10 per cent of the patients in general hospitals are neurotic or mentally ill. When suitable facilities are available, the demand for specialists increases rapidly. Furthermore, reports on tabes and traumatic brain injury have shown that the usual medical care in general hospitals lacking special departments is inadequate. A loss of interesting case material for the psychopathic hospitals need not be feared, because the hospital departments will continue to be clearing stations. A delimitation of special psychiatric and special neurologic questions is impossible. Neurology is an offshoot of internal medicine but is just as intimately connected with psychiatry. Psychiatrists must have neurologic training, and neurologists must have psychiatric training. What is needed is the training of the younger generation so that they may be equally efficient in psychiatry and neurology. Hence, for the time being, neuropsychiatric departments appear to be required. Fifty beds to each hundred thousand of population would seem to be needed. A department, however, should not have fewer than sixty nor more than from 120 to 150 beds. They must have, in the hospital, the same independent character as other departments. With every department must be associated a clinic to establish relations with the therapeutic centers, to aid the public welfare department and to organize the work of social psychiatry.

Professor Hoffmann of the central bureau of health of the city of Berlin, who is regarded as an authority in the field of hospital administration, has endorsed these demands. He declared that such special departments are to be demanded in the interest of adequate care for neurotic and mentally ill patients and also from the standpoint of general health administration. With special departments in general hospitals it would be possible to diagnose many diseases much earlier. A great deal of the preliminary investigation connected with admissions would be eliminated. Hoffmann recommends departments of from forty to eighty beds to serve a population of 100,000. In spite of the need of a separate building, such departments could be created at most general hospitals even with the present restricted funds. The cost for each patient would be higher than in the psychopathic hospitals, although not much higher than in the other special departments. From the financial point of view, the duration of treatment would be considerably shortened by the introduction of special hospital departments.

High Hospital Fees

A reduction in hospital charges is imperative as they have not been adapted to the general downward trend. On the contrary, there has been an increase from about 19,600,000 marks (\$4,664,800) in January, 1900 (\$0.49 per member), to 244,600,000 marks (\$58,214,800), or \$2.88 per member, in 1929 and to 255,300,000 marks (\$60,761,400), or \$3.11 per member in 1931. Economies can be brought about by diminishing the number of patients referred to the hospitals and by shortening the average period of hospitalization.

Professor Jadassohn Honored

The seventieth birthday of Professor Jadassohn, the Breslau ordinarius for dermatology and venereal diseases, was celebrated September 10. Jadassohn has still a wide survey of the whole field of his specialty and has advanced the knowledge of many different problems through his observation of new syndromes and his descriptions of various diseases and groups of diseases. He combines in a happy manner the clinicomorphologic method of study with biologic functional analysis. He is known for his aid in the crusade against venereal disease. He counts among his pupils eminent specialists in many countries, some of whom are now occupants of professorial chairs.

Death of Prof. Friedrich Fulleborn

Prof. Friedrich Fulleborn, the occupant of the chair of tropical medicine at the University of Hamburg and the director of the Institute for Tropical Diseases, has died at the age of 67. For thirty years he had been connected with this institute, recently as the successor of B. Nocht, in the capacity of director. He participated in many expeditions to Africa, America and Asia. He devoted himself more particularly to parasitologic and to ethnologic problems.

MADRID

Aug. 30, 1933

Prognathism Among European Rulers

Dr. F. Aguilar recently wrote an article on the frequency of prognathism among European rulers. This author, who founded the National School of Dentistry of Madrid more recently established a fund for the support of the University City of Madrid. He is also an honorary professor of various universities. His article is illustrated with a large collection of portraits copied from several galleries of paintings of famous personages of old and modern times. Dr. Aguilar states that prognathism is hereditary. In some cases it may coexist with either physical or mental degenerative anomalies but it is not in itself a sign of degeneration, as some anthropologists state. Prognathism among European rulers is not a characteristic of the Hapsburg family but is a stigma which has been inherited through several generations from King Alfonso VIII, who ruled in Castile from 1158 to 1214. In reviewing the literature, Dr. Aguilar found that Dr. Galippe of the Academy of Medicine of Paris published in 1903, an article on certain hereditary stigmas with especial reference to the frequency of prognathism, insanity and sterility, among European rulers. Galippe considered prognathism a sign of degeneration. Aguilar considers the condition a racial characteristic brought about by the intermarriage of two members of royal families who have the same inherited facial constitution. During the fifty years in which Alfonso VIII ruled in Castile, the prognathic characteristic had not yet appeared among European rulers. This king was the first European ruler who had a projecting jaw. Two grandsons of Alfonso VIII, Ferdinand, king of Castile, and Louis, king of France, had projecting jaws. In Dr. Aguilar's article about eighty pictures of prognathic rulers, including Henry II, king of Castile, his granddaughter Leonora, who married Edward the king of Portugal, Maximilian of Hapsburg, Charles V, John II, Henry IV, and the catholic sovereigns Ferdinand and Elizabeth, are shown. His article includes a historical review of twenty-eight generations of European families for a period of about 600 years. All those rulers were otherwise physically and mentally normal. Dr. Aguilar states that it is possible to determine that Mark Antony, Christopher Columbus, Hernan Cortez, Erasmus, Juan Luis Vives, Voltaire, Wagner, Haydn, Beethoven, Mirabeau, Franklin and some other notables had a projecting jaw.

Dr. Stocker on the basis of Aguilar's observations, made a study of the anatomic, physiologic and esthetic elements which enter in the structure of the human physiognomy.

Tuberculosis Among Children of Madrid

Dr. T. de Benito Landa and Miss Nieves Barrios in recent lectures reported the results of observations on children at the free antituberculosis dispensary of Madrid and of the Amparo Landa School. All the children of these groups received an injection of 0.0001 Gm. of Koch's old tuberculin. Children who did not react to the test were given a second injection of 0.0002 Gm. If no positive reaction appeared the children were given a third and last injection of 0.0005 Gm. and only when

no positive results appeared after the third injection were the children considered nontuberculous. The speakers stated that 60 per cent of the children of Madrid are tuberculous when entering school. During their stay in the schools, 20 per cent more become tuberculous. Tuberculous patients either at home or in the school, are the most frequent sources of contagion for Madrilenian children.

Deaths of Spanish Physicians

Dr Carlos Maria Cortezo, aged 83 who died recently from renal sclerosis, was a famous physician and philanthropist. Some of the positions which he held were professor of the Faculty of Medicine of Granada, head of the Hospital de la Princesa, director of public health, minister of public education, academican of the National Academy of Medicine of Madrid, and president of the cabinet of ministers in Spain. In reward of his many achievements, the king and queen bestowed decorations on various occasions, including the so-called *el Tolson de Oro*, a decoration which previously had been given only to kings and marshals. Dr Cortezo was the director of *El siglo medico* and a sincere admirer of THE JOURNAL. He was simple in character. He was the founder of the home for orphans of Spanish physicians, for which children used to call him "grandpa." Dr Cortezo is the author of a textbook of pathology, as well as of many articles read before medical and scientific societies. His book entitled *Paseos del Solitario*, in which he describes Spanish habits, places and typical Spanish scenes, is a jewel. He was one of the first physicians who stated that lice are the vectors in the transmission of typhus. On Cortezo's death, Dr Ramon y Cajal the histologist, presented the home for orphans of Spanish physicians with a memorial fund of 25,000 pesetas (\$2,500).

Dr Santiago Recasens, formerly dean of the faculty of medicine of Madrid and professor of gynecology and obstetrics, who retired two months ago on account of his age, recently died. Dr Recasens was a gynecologist and roentgenologist and a well known specialist in the treatment of cancer of the uterus.

Propaganda and the Fear of Poliomyelitis

Much confusion has arisen in Spain by some publicity falsely warning the people against the eating of bananas, which the propagandists claimed spread poliomyelitis. It is believed that the warnings were used as a means of competition among fruit dealers. Nevertheless, the banana crop on the market was not sold which caused a large loss to the dealers. The board of public health has published many articles telling the people how unscientific the idea of blaming bananas for poliomyelitis is and how obvious is the lack of any possible relation of the fruit with poliomyelitis. Fear of an epidemic of poliomyelitis is entirely unjustified, because no case of the disease has been recently reported in any province of the country.

Homage to a Rural Physician

The board of directors of the Colegio de Medicos of Madrid recently gave a banquet in honor of Dr J. Gonzalez of Daganzo, a small town 27 kilometers from Madrid. Some time ago he won the Palma prize for an article on infantile hygiene in Daganzo during the preparation of which he made a careful study of all children in town. Dr Gonzalez used to make systematic examinations of these school children. The inhabitants of his town are all vaccinated and many of them have been immunized against typhoid. Sometimes he immunized the children against diphtheria. During the last five years he has immunized infants against tuberculosis. He organizes trips to bring to Madrid young men of Daganzo whom he takes to the zoological gardens, to laboratories, to newspaper plants and to other places. During the visits Dr Gonzalez gives the

children lectures, especially on topics of hygiene and on the prevention of diseases in small towns.

New Director of Public Health

Dr J. Bejarano, a well known dermatosyphilologist of Madrid, has been appointed general director of public health. Dr Bejarano is head of the Hospital de San Juan de Dios of Madrid, a substitute professor of dermatology and syphilography in the Faculty of Medicine of Madrid, and president of the Sociedad Dermatologica Española. He has published many articles and has been appointed official delegate at various international congresses of dermatology and syphilology. He was appointed official delegate to the congress against syphilis held at Paris and at Brussels and also official speaker at the congress against cancer held at Barcelona and was head of the Azua antivenereal dispensary for a long time.

Establishment of a Mental Hospital for Prisoners

According to the *Gaceta*, the official organ of the Spanish government, the building that has been devoted to the central prison for women in Alcala de Henares will be transformed into a hospital for patients with mental disease from all the prisons in Spain. The establishment of this hospital was due to a recommendation of the recently appointed psychiatric board, which will control the hospital. A board of sanitation and hygiene to look after the health regulations of prisons will be also appointed.

Explosion of Bomb in Insurance Physician's Home

Dr R. Gutierrez is the physician of a health insurance company which insures workers on construction projects. Some of the insured workers when they suffer even a simple injury claim to be in worse condition than they really are in order to prolong the time during which they do not have to work and for which they receive wages from the insurance funds. Some of the workers have even applied corrosive substances on the lesions to give the impression that the injury was serious. More than thirty insured workers in a month received their salaries under these conditions. The insurance company recently appointed three physicians, one of whom was Dr Gutierrez, to testify on the actual condition of a group of insured members who were still receiving their salaries from the company. The physicians reported that the workers were able to go to work. The latter protested violently and threatened the physicians. A bomb recently exploded in Dr Gutierrez's house. The windows were broken and the walls cracked, but no person was injured. It is believed that the insured workers did this for revenge.

Diplomas and Foreign Physicians

The Colegio de Medicos of Madrid which is the official association of Spanish physicians, recently met to discuss problems related to a probable immigration of German physicians to Spain. Dr Magadan said that a physician whose diploma was validated by Lithuanian, Czecho and German universities recently took the examinations before members of the faculty of medicine of Madrid so as to obtain the right to practice in Spain. The candidate took the examination without the authorization of Dr Sanchez Covisa, the dean of the faculty who then annulled the examination. Dr Piga, president of the medical association, said that as yet no application for validation of diplomas has been presented by German physicians to the dean of the faculty of medicine. Dr Piga read the regulations which he said will be supported by the association in order to avoid the dangers of a greater plethora of physicians. Dr Vallejo said that he is informed that some German physicians have presented applications for validation of their diplomas by the Spanish faculties which applications were presented through an agency in Paris, of a Spanish medical journal.

ITALY

(From Our Regular Correspondent)

Sept. 15, 1933

Centenary of the Army Medical Corps

In the military hospitals in Italy, the centenary of the existence of the army medical corps was celebrated with fitting ceremonies. In 1831, military hospitals were established in the Sardinian army, and in 1832 the superior council of health was created. The regulations concerning the personnel and the work of the service were not announced until June, 1833. The personnel, in addition to the superior council, consisted of 107 physicians, nine pharmacists and 100 students of medicine. In 1853 was founded the Istituto farmaceutico militare, which is still functioning. The army medical corps has at present the Scuola di applicazione di sanità militare in Florence, departments for the diagnosis of tuberculosis, a military sanatorium (at Anzio), divisional hospitals and garrison infirmaries. Part of the medical officers are required in turn, to attend for two years the various university clinics.

Regulations for the Army Medical Service

The minister of war has revised the regulations pertaining to the army medical service, replacing the regulations adopted in 1903, regulations have also been published pertaining to the instruction in hygiene for the army, the transportation of the wounded, on nurses and sanitary aids and, for the first time on the disinfection and disinfestation services. In course of publication are also the rules for the collection of military statistics, which are designed to replace the regulations established in 1904.

Oral Surgery

The Società italiana di chirurgia della bocca e ortopedia dentofacciale met recently in Rome, under the chairmanship of Professor Zucchi.

Silenzi of Rome explained the relations between arthritic diathesis, glands of internal secretion and diseases of the alveolodental articulation. Alveolodental arthritis of which pyorrhea is a direct consequence, is intimately connected with dysfunction of the endocrine glands and with a disturbed coloidal equilibrium.

Magalotti of Rome in explaining orthodontic treatments called attention to certain dental malpositions which tend to become worse as time goes on, especially protrusion of the antero-superior teeth. If one does not resort to surgical interventions he can apply Angles' "ribbon arch" method which requires a longer period of time for the correction.

Rosa of Rome reported a case of epulis. The tumor was in the alveolar cavity of the upper right wisdom tooth, in a patient aged 40. The microscopic examination revealed that the periphery was composed of a stroma of connective tissue with an invasion of round cells while the center was a dense fibrous structure containing numerous bony trabeculae in process of formation.

Piperno of Rome presented a collection of dentures taken from the mouths of patients, in whom, owing to their irrational nature, various disturbances had been caused. This menace is now eliminated since a recent Italian law prohibits dental technicians who are not graduate dentists from applying dentures.

Meeting of Phthisiologists

The phthisiologists about Venice held recently a convention at Udine, under the chairmanship of Professor Grasbarrini.

Fasiani presented a paper on renal tuberculosis. Tuberculous types occurring in the urinary passages have their onset in the kidney following metastatic transportation of bacilli by way of the blood stream. The diagnosis of the nature and the seat of the lesion is difficult. In doing nephrectomy, one must take account of the consequences of the accidental removal

of the suprarenal gland. The record of recoveries is 75 per cent in the unilateral cases, and in some series of cases of early operation it has been 90 per cent. The speaker holds that a person with one kidney removed may be regarded as an individual of normal working capacity.

The speaker emphasized that persons with an open type of tuberculosis of the kidney should be regarded as dangerous the same as patients with open pulmonary types, hence the importance of early diagnosis.

Calzavara attributed fistulas resulting from nephrectomy for tuberculosis to the ureteral stump that remains in the wound area. He has been able to prevent them by applying the retention catheter to his patients operated on.

De Favento presented a study on tuberculous bacilluria of the unimpaired kidneys, a condition which may arise in patients with pulmonary tuberculosis. This fact points to the need of refraining from nephrectomy based solely on the discovery of bacilli in the urine secured by ureteral catheterization.

Biffis in discussing the social problem of tuberculosis advocated instituting a certificate of immunity at least from open tuberculosis in connection with a proposed marriage.

Varisco of Udine reported the results of his observations on the relation between emigration and tuberculosis. He pointed out that the number of persons returning to their former homes when they become affected with specific pulmonary types of tuberculosis is sufficient to influence the tuberculosis morbidity of a given region.

Decline in Mortality from Tuberculosis

According to recent statistics, the mortality from tuberculosis has diminished in all regions of Italy from 156 per hundred thousand of population in 1924 to 108 in 1931 and to 96 in 1932 which constitutes a diminution of about 40 per cent. According to the statistics of the Istituto centrale di statistica the total number of deaths during the first quarter of 1933 was 9,592 in comparison with 11,173 during the first six months of 1932.

Marriages

BRICEY MILTON RHODES to Mrs Eunice Bricey Burns Thornton, both of Tallahassee, Fla. at Pensacola August 22.

HOWE REESE COLEMAN JR. Lexington Va. to Miss Virginia Hightower of Montgomery, Ala., August 22.

RANDOLPH BRYAN GRINNAN JR. Boston to Miss Adelaide Richardson Buist of Brooklyn, August 5.

ROBERT ELMER JOHNSON, Danville, Ill., to Miss Virginia Blunk at Indianapolis August 31.

HYMAN J. BURSTEIN Decatur Ill., to Miss Edythe Mae Cohen of Springfield, August 27.

EMMETT B. FRAZER Mobile Ala., to Miss Mary Jane Knight of New Albany, Ind. August 29.

GRACE LINE HONMAN, Los Angeles, to Mr. Oliver Houston of Long Beach Calif. April 21.

CLAUDE DINKINS JOHNSON to Miss Rosalie Kelly, both of Nashville Tenn., August 22.

ROBERT BUCKLEY to Miss Maxine Elizabeth Frix, both of Richmond Va. August 8.

HAROLD E. STRICKER to Miss Maxine Elizabeth Cross both of Toledo, Ohio recently.

RAYMOND E. HOLBEN Lincoln, Ill., to Miss Ella De Frates of Springfield, August 28.

JOSEPH SANTE DIASIO to Dr. CLARA DI BENEDETTO, both of New York, in October.

ALBERT D. DE HAVEN to Miss Roberta Shaw both of Xenia, Ohio recently.

HAROLD A. CONRAD to Miss Lucile Hertzer, both of Cleveland recently.

HUGH L. BASS Louisville Ky. to Miss Valeria Edelen August 10.

Deaths

John Staige Davis • University, Va University of Virginia Department of Medicine, Charlottesville, 1889, member of the House of Delegates of the American Medical Association in 1912, instructor in medical biology and pathology, 1893-1894, adjunct professor of pathology and hygiene, 1894-1900 and professor of medicine, 1900-1930, at his alma mater fellow of the American College of Physicians, past president of the Medical Society of Virginia aged 67, died, September 21

Jacob Willard Farrow • Dover, N J, Long Island College Hospital Brooklyn, 1895, member of the Associated Anesthetists of the United States and Canada, formerly member of the board of education, served during the World War, on the staff of the Dover General Hospital, aged 60, died suddenly October 14, of heart disease

Thomas Faith, Chicago, College of Physicians and Surgeons of Chicago, 1893 member of the Illinois State Medical Society and the American Academy of Ophthalmology and Oto-Laryngology, on the staff of the South Shore Hospital, aged 61, died, October 16 of arteriosclerosis and cerebral hemorrhage

Michael Schiller, New York, Columbia University College of Physicians and Surgeons, New York 1896 member of the Medical Society of the State of New York aged 60 on the staffs of the Harlem Hospital and the New York Post Graduate Medical School and Hospital, where he died, October 5

Herbert Eugene Smith, Los Gatos Calif University of Pennsylvania School of Medicine, Philadelphia, 1882, instructor of chemistry, 1882-1885, professor of chemistry and dean 1885-1910 and since 1910 emeritus professor Yale University School of Medicine, New Haven, Conn aged 75, died, October 9

William Edgar Bates, Centerport Pa, Jefferson Medical College of Philadelphia 1886, member of the Medical Society of the State of Pennsylvania aged 67 died, September 16, in St Joseph's Hospital, Reading, of sclerosis of the coronary arteries and heart disease

Nelson B. Oliphant • Trenton, N J, University of Pennsylvania School of Medicine, Philadelphia, 1880 past president of the medical board and formerly on the staff of the Mercer Hospital aged 76 died July 16, in Southport Me of acute intestinal obstruction

Charles Amedee Robert, St Hyacinthe Que Canada, School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal, 1899 aged 61 died, September 5, of nephritis and cerebral hemorrhage

Frank Light, Ottawa, Ohio Columbus Medical College, 1883 member of the Ohio State Medical Association formerly member of the board of education and county health commissioner, aged 72, died September 27 of cerebral hemorrhage

Fletcher Johnson Towler • Lyons N Y Harvard University Medical School Boston 1921 bank president and president of the board of education aged 38 died October 8, in a hospital at Cleveland, of peritonitis following an operation

Edgar W Boardman • Parsons Kan, Hahnemann Medical College and Hospital, Chicago 1884 past president of the Labette County Medical Society, on the staff of the Mercy Hospital aged 69 died September 22 of heart disease

John Alvin Orr, Jr, Addis Ababa Abyssinia Africa University of Pennsylvania School of Medicine Philadelphia 1929 medical missionary aged 30 on the staff of the George Memorial Hospital, where he died September 17 of typhus

John L Van Dyke, Paris Texas University of Louisville (Ky) School of Medicine 1883 member of the State Medical Association of Texas, on the staff of the Sanitarium of Paris aged 75 died September 9 of cerebral hemorrhage

Minnie Crouch Dunlap Lexington Ky Southwestern Homeopathic Medical College and Hospital Louisville 1899 for many years on the staff of the Eastern State Hospital aged 75 died October 2 of carcinoma of the colon

William Frederick Smith Boise Idaho Medical College of Virginia Richmond 1886 member of the Idaho State Medical Association formerly on the staff of St Luke's Hospital aged 68 died September 9 of heart disease

Bureau of Investigation

KOLLOYD

Another Fraudulently Exploited "Ulcer Cure"

The postal authorities have recently declared the exploitation of a product known as 'Kolloyd' as a "scheme for obtaining money through the mails by means of false and fraudulent pretenses, representations and promises" and have closed the mails to the business.

Kolloyd was put on the market by what was first known as Kolloidal Research Laboratories, Inc. This concern was incorporated under Illinois laws April 30, 1931, the names of the incorporators being, according to the record, A. C. Linen and C. T. Myles and G. Kaplan, all of 127 North Dearborn Street Chicago. On Feb. 8, 1932, the name was changed to Kolloyd Laboratories, Inc. Under its earlier name the company did business from 1352 Madison Park Chicago but it was not listed in the Chicago telephone directory. The stationery, however, gave its telephone number as Kenwood 0760. Investigation disclosed that this was the home address and telephone number of one Ignatius Barnard.

STOPS ACID PAIN IN 3 MINUTES

STOMACH

ULCERS HEALED IN 3 WEEKS

Sooner or later you will wake up to the fact that soda, magnesia, bismuth, slippery powders and alkaline tablets bring back MORE acid than you had to start with—the more you take the sicker you will be. Investigate the KOLLOYD treatment which carries the acid OUT of the body—which spreads a protective coating over stomach and duodenum. Not a drug, acts mechanically. Made 10,000 chronic sufferers well in past year. Trial box and booklet of testimonials free. Address:

KOLLOYD LABORATORIES
Dept. 112-C-332 S. Michigan Blvd., Chicago

WRITE FOR FREE BOX OF *Kolloyd*

According to a report received in February, 1932, the company had for its president Ignatius Barnard, with Jeanette L. Barnard, his wife, as secretary and treasurer, M. T. Horwich as vice-president, and Henry Posner as a member of its board of directors. Ignatius Barnard was, but apparently is no longer, connected with an advertising agency. As this department of THE JOURNAL has repeatedly pointed out, the most important asset for the commercial exploitation of a "patent medicine" is a knowledge of advertising. A knowledge of medicine, pharmacy or chemistry is quite unnecessary. The two men, Horwich and Posner, were reported to be respectively, president of a printing concern and a mortgage banker. By 1933 the company had apparently become a closed corporation, for the names of the officers and directors filed in a report to the Secretary of State of Illinois in February of this year were Ignatius Barnard, President and director, Ruth Barnard, Secretary and director, and Jeanette L. Barnard, Treasurer and director.

The Hon. Karl A. Crowley, Solicitor for the Post Office Department in an extensive memorandum to the Postmaster-General recommending the issuance of a fraud order against this concern, brings out some interesting facts regarding this piece of quackery. The memorandum states that the concern was organized by Barnard and his wife and two others whose names have not been disclosed but who furnished the capital. At the hearing held in Washington—a hearing that occupied nine days and a transcript of the record of which comprised over 800 typewritten pages—Barnard admitted that he held no degree as a chemist and that his knowledge of therapeutics was limited to such information as he claimed to have acquired by having consulted doctors regarding his own case and the reading of medical works on the treatment of gastro intestinal

ulcers The Solicitor reports, further, that Barnard had had about twenty-five years' experience in writing advertisements, including especially the preparation of advertisements for "patent medicines" Barnard admitted writing the copy for his Kolloyd nostrum Barnard also claimed to have suffered from ulcers of the stomach for twenty-eight years and to have been unsuccessfully treated by several physicians, but claimed to have been cured by the use of a product containing colloidal hydroxide of aluminum He admitted, however, that he still has recurrences of his trouble

Kolloyd has been sold in two forms—a tablet and capsule It consisted of about equal amounts of aluminum hydroxide and milk sugar

The Bureau of Investigation has accumulated an extensive collection of advertising and particularly the follow-up letters put out both under the name of Kolloidal Research Laboratories, Inc., and Kolloyd Laboratories, Inc. In a four-page letter signed by Ignatius Barnard and reproduced in imitation typewriting, Barnard purports to tell of his own experience In the first page of this letter he declares that he had been treated by some of the best physicians in the United States both individually and in clinics, but without success Barnard then continues

So I went to Europe—hoping I could find something there And I did In Vienna I met Prof Temple—72 years old—a famous portrait painter I noticed he kept a little roll of tablets in his pocket and every once in a while he took one. I was dieting—afraid to eat—or drink—or smoke He laughed at me, listened to my story—and told me—he too had ulcer and hyperacidity for over 20 years—he had had an operation—the trouble came back—and a physician finally told him about those little tablets

Believe it or not—I was comfortable in a few minutes after taking a couple of these tablets Half an hour later the pain came back and I took a couple more and became comfortable again This time I had no pain by the time the next meal rolled around and by taking the tablets I didn't have any

To make a long story short I brought these tablets to America I call them KOLLOYD tablets They are Colloidal Hydroxide of Aluminum I have given them to hundreds of my friends—and some of the recoveries sound like fairy tales

Not only do "some of the recoveries sound like fairy-tales," but this entire yarn was a fairy-tale At the hearing Barnard admitted that he did *not* go to Europe that he *never* met Professor Temple that he *never* obtained any tablets from him, and that he *never* brought any tablets to America!

In all of the elaborate advertising and high-pressure salesmanship on Kolloyd, the changes are rung on the thesis that by the taking of Kolloyd a person can cure a stomach ulcer in three weeks At the Washington hearing Barnard attempted to deny that the advertising was intended to convey such an idea Even the medical expert employed by the Kolloyd concern to testify at the hearing had to admit that the shortest length of time in which he had observed an ulcer to be thoroughly healed was over two months The government brought out at the hearing that medical authorities are generally agreed that, in the healing of a peptic or duodenal ulcer next to diet and rest, the time element is of prime importance and that the usual period of healing is one of several months' duration Even in such cases it is pre supposed that the patient has been properly hospitalized or that his regimen of rest and diet is under strict scientific supervision

In some of its advertising the Kolloyd concern published what the public could not help but believe was a testimonial credited to "Drs Einsel and Rowland Ohio The facts are that the quotation was a garbled combination of several sentences from an article published by Drs I H Einsel and V C Rowland of Cleveland Ohio on 'The Aluminum Hydroxide Treatment of Peptic Ulcer' that was published in the *Ohio State Medical Journal* March 1932 Barnard left out of the quotation all statements that would contradict the Kolloyd misrepresentation The actual statement made by Drs Einsel and Rowland in their article follows The words put in italics were left out in the Kolloyd advertising

So far we have treated thirteen cases of duodenal ulcer for an average length of time of five months They all responded promptly and have had complete symptomatic relief There have been no failures in this small series of aluminum hydroxide cream cases There have been no side reactions to the drug, no vomiting or toxic symptoms or complications of any kind or of any kind

Blood analysis shows practically no absorption of aluminum hydroxide or of any other substance in the case of the acid-base balance There is no evidence of toxic action upon kidneys or other organs

Obviously the matter quoted by Barnard did not represent the opinions of Doctors Einsel and Rowland but was garbled to suit Barnard's purpose He eliminated all reference to the five months' period of treatment and the fact that no "cures" were reported, but only symptomatic relief, because such reference would have given the lie to the claim that Kolloyd would cure ulcers in three weeks

It was further brought out at the hearing that Barnard's concern emphasized in its advertising that "you can eat practically everything as soon as you start the Kolloyd treatment" and that "no dieting is necessary" Yet, those who sent money for Kolloyd received a pamphlet containing a list of foods they were told to avoid! It was brought out, too, that while the advertising claimed that Kolloyd was not a "patent medicine" the evidence shows that apparently the only reason it was not a "patent medicine" was that Barnard had been advised by his attorneys that as another similar preparation had already secured the patent, it would be inadvisable for him to apply for a patent, as it was not likely that he would succeed in obtaining it Evidence was also submitted to show that Kolloyd, which sold through the mails for \$2 a box, was of the same composition as another preparation which could be bought in drug stores for 75 cents

In view of the facts already dealt with and others referred to in the memorandum, the Solicitor recommended the issuance of a fraud order against the Kolloidal Research Laboratories, Inc., the Kolloyd Laboratories Inc., and J L Barnard Manager Postmaster General Farley closed the mails to this concern June 28 1933

BERYLLIUM RICKETS

To the Editor—Your editorial on beryllium rickets in the issue of September 30 completely overlooks—as did the Canadian investigators you cite—a very important fact that may invalidate your conclusions This is that beryllium has distinct radioactive properties, as has been proved at the California Institute of Technology

The bone lesions observed may indeed resemble rickets, but it would seem that they may also have quite as much resemblance to the bone lesions following the ingestion of minute quantities of radium compounds or other radioactive substances The alteration in blood plasma may be due, as suggested, to precipitation of phosphates by beryllium ions, but radioactivity is also damaging to blood plasma

Without any intention of reflecting on the work of these investigators, it may be said that the research can hardly be called conclusive, and such a term as "beryllium rickets" cannot be justified until the possible effects of beryllium's radioactivity have been thoroughly examined

JOHN G HANNA Dunedin Fla

RESEARCH ON VITAMINS AND HORMONES

To the Editor—I chanced to read the report by your Berlin correspondent entitled "Research on Vitamins and Hormones" (*THE JOURNAL*, September 9, p 867) shortly after having consulted the original paper by Kuhn and collaborators (*Ber d Deutsche Chem Gesellsch* 66 B, 1034) Kuhn gave evidence that the antipellagra factor is not identical with the hachromes and referred to the work of P G6rgy who designated the antipellagra factor vitamin H

Further since evidence has been accumulating in recent years that the vitamin B complex contains two or more factors in addition to B₁ it may not be entirely correct to hold that a further colorless factor derived from yeast (complementary to the hachromes) was previously unknown Whether

"vitamin H" is a component of this particular yeast fraction is not clear, since Gyorgy's report is not yet available to me. However, Kuhn pointed out that purified "vitamin H" is colorless. Finally, it is questionable whether crystalline lactoflavin, alone, should be called "vitamin B," since B generally is estimated on the basis of growth-promoting effectiveness. Notwithstanding, the work of Kuhn and others appears to be the first successful step toward elucidating the chemistry of the vitamin G complex, knowledge of which heretofore has lagged behind that of vitamins A, B₁, C and D.

TREATMENT OF WASSERMANN FAST SYPHILIS

To the Editor.—I am trying to get information on the approved effective treatment of Wassermann fast cases. The use of milk injections such as aolan and autotransfusions has been suggested to me but the proper technique and its use in relationship to the arsenicals were not explained. I have reason to feel that an injection of milk the day prior to an intravenous arsenical would provoke a terrific reaction with chills and fever. I believe that the autotransfusion would probably give the same result. I wish you would kindly send me the desired information and also your opinion regarding the reactions I have referred to above when milk or autotransfusions are used the day prior to an intravenous injection and the proper technique. Can these measures be also used effectively in connection with the administration of bismuth? Please do not publish my name.

M D Colorado

ANSWER.—The therapeutic efforts for Wassermann fastness suggested by the correspondent put the cart before the horse. Before one can discuss intelligently the treatment for this condition, one must have much more information as to its probable cause. Wassermann fastness is a frequent accompaniment of all types of late syphilis. In many instances if not in all, it is an expression of the sensitivity of the serologic test employed rather than an indicator of persistent lesions in the patient. It is, however, particularly associated with cardiovascular and visceral lesions, with late bone lesions, with certain types of central nervous system syphilis, and with late congenital syphilis.

In dealing with this situation, the important thing is not to attempt various modifications of treatment procedures in order to reduce the Wassermann reaction to negative but to investigate the patient thoroughly to find out what is keeping the test positive. If the original examination has not disclosed the presence of a lesion in one of the organs or systems enumerated, complete physical reexamination should be performed with careful emphasis, particularly on the cardiovascular, osseous and central nervous system. Teleroentgenographic examination of the cardiovascular area should be carried out to make sure that aortic dilatation has not been overlooked in the physical examination. The accessible bones should be carefully palpated and any roughening or thickening checked by roentgen examination. The spinal fluid must be examined. Neurosyphilis may be asymptomatic rather than clinically apparent. Not until after the performance of such a searching physical and laboratory examination is it profitable to discuss the treatment of Wassermann fastness.

If the apparent cause of the persistently positive blood test is cardiovascular syphilis, visceral syphilis or neurosyphilis the proper treatment to be instituted is the treatment of these conditions and no attention whatever need be paid to the question of ultimate reversal of the blood Wassermann reaction. The desideratum of treatment is not to render the Wassermann reaction negative but to relieve symptoms, prevent clinical progression and prolong life. If these three aims can be accomplished it makes no difference to the patient or his physician whether the Wassermann reaction is positive or negative.

If the apparent cause of Wassermann fastness is cutaneous, osseous or late congenital syphilis and if no evidences of cardiovascular, visceral or nervous system involvement are present, the patient may be regarded as in the same category as Wassermann fast patients with latent syphilis. Obvious lesions, if present, almost always heal promptly and relapse is no more

frequent than in patients who are not Wassermann fast. Treatment may proceed, therefore, not on the basis of lesions actually detectable (as in cardiovascular syphilis, visceral syphilis or neurosyphilis) but on the basis of a suspicion that, because of the Wassermann fastness, such potentially grave lesions may be present but below the level of clinical recognition. The treatment of the Wassermann fast patient with late congenital, osseous or latent syphilis is thus prolonged not because of lesions which the patient actually has, but because of lesions which, if untreated, he may develop. It is customary in many clinics to treat such patients continuously with the arsphenamines and a heavy metal in alternation for a minimum period of two years. No special attempts are made by utilizing other than the usual drugs, by intensification of treatment, or by the adoption of such nonspecific measures as fever therapy, to bring about reversal of the Wassermann reaction.

On the completion of two years of treatment, the patient is placed on probation just as if his serologic response had been more satisfactory. Subsequent observation both from the serologic and the clinical standpoint, is rigidly insisted on. Periodic physical examination throughout life is essential, with special emphasis on the cardiovascular apparatus. Curiously enough in the benign types of Wassermann fastness, especially in latent but also in osseous and late congenital syphilis there is a definite tendency for the Wassermann reaction spontaneously to become negative after the cessation of treatment.

The significance of Wassermann fastness for the patient's future course is not as yet certain. In cardiovascular and neurosyphilis, it is probably of no special importance. Progression in spite of treatment or a favorable response to treatment are equally common in patients Wassermann fast and in those in whom reasonably prompt Wassermann reversal is secured. In these two conditions what happens to the blood Wassermann reaction is of little importance as compared to relief of symptoms, clinical arrest and prolongation of life. In neurosyphilis the response of the blood Wassermann reaction is vastly less important than the response of the spinal fluid. In latent, late osseous and cutaneous, and in late congenital syphilis relapse of the original lesion or the fresh appearance of new lesions is no more frequent in patients Wassermann fast than in those who are not and in either case negligible if treatment has been prolonged for two years.

There is no rational reason for the use of milk injections, aolan or autotransfusion in this situation. Such injections given a day previously to the use of an intravenous arsenical would not, however, increase the reaction that might be caused by the arsenical.

PAROXYSMAL AURICULAR FIBRILLATION

To the Editor.—An obese woman, aged 52, has had several surgical operations on the abdomen. She is subject to attacks which I have interpreted as paroxysmal fibrillation. Between these attacks there is no evidence of heart disease except a moderate increase in the area of cardiac dullness which is in keeping with an obese habitus and exaggerated by a high diaphragm. The blood pressure between attacks is 180 systolic, 125 diastolic. The first attack occurred two years ago after a cholecystectomy. There have been several subsequent attacks at irregular intervals. There is no history suggestive of earlier heart disease except the moderate hypertension. During attacks the apical rate is about 140 or nearly as it can be counted. The heart action is completely irregular as to force and rhythm with marked pulse deficit. At these times there is considerable dyspnea and cyanosis. I have seen the patient in but two of these attacks but precordial pain made its first appearance with the last. This did not respond to vasodilators but did subside with the attack several hours later. The attacks start suddenly and end quite as suddenly under intensive digitalization within six to eight hours. The two attacks which I observed were separated by an interval of four months. It was unnecessary to give digitalis up to the calculated physiologic dose in either instance. On cessation of an attack, the resting pulse rate becomes 68 and is perfectly regular.

H W Dorr MD Ashton Idaho

ANSWER.—Paroxysmal auricular fibrillation in a heart that is apparently normal is probably of minor significance of itself and such patients may attain their normal expectancy as far as the heart is concerned. There is some reason for supposing that such cases occasionally occur in hearts without any organic pathologic changes. Frequently these recurring paroxysmal attacks are associated with gastro-intestinal disorders. That such cases of paroxysmal auricular fibrillation may occur with out evident pathologic changes does not alter the fact that these should always be suspected. When the attacks are so far apart, they may as well be left alone as far as medication is concerned. An attempt should be made to determine just what factors predispose to the attacks and the attacks should be avoided as far as possible. Bed rest, with possibly some mild sedative, is usually sufficient for the attack. Digitalis is usually

cessary, as the attack will usually subside with rest alone is reason for thinking that digitalis may occasionally perpetuate an attack that otherwise would be temporary attacks become frequent, a daily dosage of quinidine may be used to prevent their recurrence. Doses of 4 to 1 Gm or more daily, if necessary, should be used attacks as infrequent as they are in this case, this is not

NONEMERGENCY SURGERY IN PATIENTS WITH UNTREATED SYPHILIS

Editor—I should like to know the consensus concerning the use of nonemergency operations, such as uncomplicated berna, formed on a patient with untreated syphilis as shown by a four sermann and Kahn test

P H KENNEDY MD, Youngstown Ohio

ANSWER—In general it is accepted as inadvisable to perform nonemergency operations on patients with untreated syphilis prior to a careful investigation of the status of the syphilitic infection and, if indicated, necessary preliminary treatment. The reasons for this position include the enormous amount of risk to which surgeons and operating assistants are subjected by operations on patients with early syphilis in which a spirochetemia is present as well as risk associated with local infectious lesions. Operators dealing with the oral and nasal cavities and the anus and genital regions are particularly subject to risks on this score. Every positive Wassermann reaction in a patient in whom such an operation is contemplated should lead to a proper examination for the status of his syphilis and the patient should be subjected to preliminary sterilizing treatment. When, in later infections, complications of the nervous system are recognized, symptoms may not infrequently follow the shock of operation, producing a most disconcerting and sometimes serious group of unnecessary complications. The matter of healing of operative wounds in patients with uncomplicated syphilitic infection has been investigated by Goeckerman and others and these studies have shown that risk of nonunion or gummatous infiltration of the operative wound is extremely small. Nevertheless it does sometimes occur, particularly in patients who present unrecognized cutaneous lesions of a gummatous type at the time the operation is performed. In even so apparently remote a field as tonsillectomy in patients with untreated prenatal syphilis the proportion of severe scarring following gummatous infiltration and destruction of the pillars uvula and soft palate is a definite and serious risk. Operations on the nasal septum in patients with positive Wassermann reactions also may lead to extensive bone destruction instead of healing with collapse of the nose, saddle deformity and serious disfigurement.

In view of all these facts the statement stands, therefore, that syphilologic investigation and appropriate treatment is called for in patients with four plus Wassermann and Kahn reactions prior to the performance of nonemergency operations

PROPHYLAXIS OF LEAD POISONING IN PAPER MILLS

To the Editor—I have under my care a group of men in a pulp and paper mill who work in the digester room handling litharge. I am using all measures possible to prevent the men from getting lead poisoning. I should like to get your advice concerning the giving of small doses of potassium iodide at intervals as a prophylactic measure. Would there be any contraindication to the giving of potassium iodide? I have been giving these men frequent physical examinations and likewise doing blood examinations especially watching for stippling. The urine examination for lead is rather hard to carry out as a routine procedure. Could you tell me any simpler methods? I should appreciate any suggestions that you may give. Please omit name

MD Wisconsin

ANSWER—At present there is diversity of opinion as to the preferable medical care of persons who may be absorbing lead and who may shortly present clinical lead poisoning.

The work of Kehoe and his associates apparently maintains the undesirability of the administration of any substances for the purpose of chelating. The promotion of chemical lead poisoning is thus believed to be favored. In keeping with the trend of this work all effort should be made to prevent the development of lead poisoning but when such does arise chelating should be left to physiologic processes. Removal from further exposure is likely to be followed by the slow natural elimination of the greater portion of the lead during several ensuing months.

Contrary to this concept the work of Aub and his associates favors the use under carefully supervised conditions of divers medicaments and procedures conducive to the hastened elimination of lead from the body. In view of this situation no unreserved recommendations should be made at this time with

respect to that part of the query related to the use of potassium iodide. For persons well protected against lead intake and whose personal hygiene as to diet, constipation and so on is proper, the use of potassium iodide seems unwarranted. More is to be expected from the control of exposure, the prevention of ordinary gastro-intestinal disturbances, careful monthly physical examination, with weekly physical inspections and interrogation, the rotation of services in this department, and the elimination of workers prone to infections and gastro-intestinal upsets. An occasional examination of the urine for lead is of dubious value. The technic is long and the opportunities for errors are many.

Routine blood examinations are valuable but not definitive. Most may be expected from a regimen involving dependence on no one test but on the combination of several, including blood changes, weight status, and results of interrogations of workers as to manifestations. Much information may be found as to the significance of trivial deviations from the normal in "Lead Poisoning" Report of Committee on Lead Poisoning, American Public Health Association, 1930.

ACETYLENE WELDING AND METAL FUME FEVER

To the Editor—I have a patient an acetylene welder who on July 6 after getting a considerable amount more than usual of fumes on July 5 and 6 became completely exhausted. A severe pain developed in the lower right thoracic and right lumbar region. The temperature ranged from 101 to 102 F and there was persistent coughing with expectoration of a considerable amount of bright red blood. Auscultation showed distant breath sounds in the right lower lobe and absence of breath sounds in the right axilla. A phlebitis of the left leg and then of the thigh developed. The urine showed a trace of albumin and a few hyaline and granular casts. Leukocytes numbered 11,750 polymorphonuclears 74 per cent. He gradually improved but continued to expectorate blood until August 9 when an intense pain developed in the left side of the chest the fever rose to 103 and the leukocytes numbered 16,000 with 90 per cent polymorphonuclears. Auscultation showed a slight pleuritic rub in the left axillary line at about the fifth sixth and seventh ribs. There was almost total absence of breath sounds in the upper half of the lower left lobe. On the 12th he expectorated about an ounce of dark foul smelling blood and continued to expectorate small amounts of blood of the same character for several days when the blood again became bright red. The sputum has been examined four times and was negative for tubercle bacilli. The patient's temperature has been normal for five days but on the 26th he began to complain of pain in the right lung again. Is this condition probably occupational? What is the prognosis? Please omit name

MD, Mississippi

ANSWER—This inquiry should have furnished information as to the type of metal being welded. The condition described is not characteristic of the action of acetylene or of any of its more frequent impurities. It is not entirely characteristic of metal fume fever and probably is not entirely related to occupation as to the cause.

Hydrogen arsenide (arsine) and hydrogen phosphide (phosphine), together with carbon monoxide and all possible impurities in acetylene, occasionally lead to their characteristic actions on exposed acetylene welders.

Metal fume fever is more often encountered following work with galvanized material or with metal otherwise containing zinc.

Secondary infectious processes of the respiratory tract, after minor attacks of metal fume fever, are known. It is possible that the condition described is wholly unrelated to work.

FRIGIDITY IN WOMEN

To the Editor—Will you kindly give me information on the following problem. A white woman aged 23 married one year has never experienced orgasm during sexual intercourse. She is an active healthy woman. Physical examination shows no abnormalities of the genitalia. She states that at no time during her life has she ever had any sexual sensation. There are no psychic factors that disturb her. Is there anything to be done to remedy the condition. Please omit name

MD Kansas

ANSWER—It is not at all unusual for a modestly brought up woman to experience neither sexual desire nor orgasm during the first year of married life. Many cases however, may be due to the husband who may be suffering from premature or rapid ejaculation thus getting through with the coital act before the wife has had a chance to come to orgasm. In other cases awkward coitus on the part of the husband may cause both painful coitus and lack of orgasm. It should be determined whether the wife during the period of engagement experienced any sexual pleasure during the spooning. If she did it shows that the sexual sense is not absent but has not yet been awakened during coitus. Many of these women experience pleasure from masturbation either by themselves or if done by the husband. In such cases the sexual centers in the brain which are in connection with the external genitals

Dr. Robert H. H. H. H.

E. M. & H. H. H.

have been developed at the expense of those areas in the brain connected with the internal genitals. In the latter cases there is sometimes found a marked diminution of sensation in the vaginal mucous membrane. The treatment for the condition just mentioned is giving up the practice of masturbation and indulging in regular sexual intercourse and treatment of the insensitive vaginal mucous membrane by the galvanic sinusoidal current with a vaginal electrode as suggested by Huhner (Diagnosis and Treatment of Impotence in the Male and Female, *Am Med* 27 144 [April] 1932). Of course there are cases of absolute congenital frigidity for which nothing can be done. These cases are however, comparatively infrequent and should be examined with a view of determining the possibility of hermaphroditism, homosexuality or other inversion.

CEPHEMATOMA IN INFANT

To the Editor—A woman aged 18 has just brought to me her first baby who is 3 months old. She states that she was in labor about thirty hours and that there was an immense caput succedaneum over most of the upper and posterior surface of the baby's head following birth. At present there is over the right parieto-occipital region quite an elevated area extending anteroposteriorly about an inch in elevation at the maximum height and 3 inches long. This is of bony hardness and firmness. What would you advise for this condition? Please omit name.

M D South Carolina

ANSWER—Cepheatomas are said to occur about once in every 200 deliveries. The condition is sometimes associated with hemorrhages in other organs, which may be due to the hemorrhagic diathesis. The hemorrhage that constitutes the cepheatomoma is usually situated over one of the parietal bones, rarely over the occipital, frontal or temporal bones. As a rule the tumor mass is not observed until the second or third day of life, though the blood continues to extravasate or the mass increases. About the end of the first week a hard ring appears about the periphery of the mass, though the center of the tumor is soft and suggests the presence of fluid. In small hematomas the swelling may disappear within three or four weeks though in larger ones from six to eight weeks or a longer time may elapse. The bony ridge that forms the periphery of the cepheatomoma may at times remain permanent or the entire mass may become ossified and persist as a flat or projecting exostosis. The general health is not affected, there is no pain, and the loss of blood is as a rule not sufficient to produce constitutional effects.

In view of the fact that many of these hematomas resorb spontaneously, no special treatment is required. During the first few days, aspiration of the blood by puncture has been employed but this procedure increases the hazard of infection. If infection has occurred, incision and drainage are indicated. In the case described, manifested by the elevated area, no treatment is advised. There is still time for resorption of some of this newly formed bony tissue, and no further complications need be anticipated.

MENORRHAGIA

To the Editor—A woman aged 59 for two and one half years has periodically menstruated approximately every three months each of these periods lasting about two weeks or as on one occasion for about a month. These periods are preceded by backache. The patient otherwise feels quite well. The flow at these times is heavy and might be termed hemorrhage but is slowed by bed rest and ergot. The patient has no symptoms suggestive of the menopause. Examination reveals nothing as far as the pelvis is concerned except a slight cervical erosion which takes the stain by Schiller's test only slightly. The woman is obese and one could not be absolutely certain as to the exact size of the uterus but after repeated examinations I am reasonably certain that it is of about normal size. Leukorrhea is not complained of and appeared to only a small degree at the examinations. There is absolutely no spotting or vaginal bleeding except at the times stated. How is this case to be handled? Is a curettage indicated to rule out malignancy? Please omit name.

M D Illinois

ANSWER—Most probably the periodic bleedings in this case are physiologic and not due to a malignant growth. However, since the woman is 59 years old and the flow of blood is usually prolonged and profuse it is advisable to perform a curettement to make certain that there is nothing abnormal inside the uterine cavity. The endometrium should of course, be subjected to a careful microscopic examination to rule out carcinoma. Even if the endometrium is normal one must bear in mind the possibility of a growth in one or both ovaries. Such neoplasms may be difficult to rule out by bimanual examination in this patient because she is obese. If the patient is given a general anesthetic for the curettement an examination while she is anesthetized may reveal the exact condition of the uterus and adnexa. If the bimanual examination under anesthesia fails to reveal any abnormalities and the endometrium is normal nothing further need be done unless the bleedings

again become profuse. In this event radium should be inserted into the uterine cavity to put a stop to the menstrual function. Radium may, of course, be used at the time of the curettement. If carcinoma is found in the uterine endometrium, a panhysterectomy may be performed or radium may be employed.

LICHEN SIMPLEX CHRONICUS

To the Editor—A woman has an eruption on the inner aspect of the lower limb which has been present for thirteen years. It extends from below the knee on the inner side of the limb down to about the lower third of the limb. She states that at first it was of an oozing character but after about six months it became dry and has remained so ever since. It is covered with a thin flaky scale which is easily removed and there is no bleeding when this is done. It itches a great deal in the evening especially when the stocking is removed but not so much during the day. When the scales are removed the skin underneath has a purplish cast and throughout the lesion are lighter areas of a yellow color. She has some medium sized varicosities just above the lesion but she states that she had these injected by a physician who thought the lesion a varicose ulcer but the treatment did not alter the course of the eruption. She is now 65 years old and otherwise in good health.

II PAUL JOHNSON, M D Harmony, Minn

ANSWER—The patient apparently has a patch of lichen simplex chronicus, which is regarded by most workers as chronic papular eczema. The condition is called neurodermite by the French. It is a chronic papular dermatosis occurring in the form of patches and accompanied or preceded by severe itching. The treatment in general is that applied to circumscribed chronic eczema. X-rays and tar are particularly useful measures. X-rays should be given in small fractional doses. When using tar the aim is to produce a short, subacute inflammatory reaction which is allowed to subside of itself. Pure crude coal tar is applied to the patch and allowed to dry. On a surface which is not subject to much trauma the layer of tar will remain on the skin for several days before it flakes off, and a new layer is then applied. This treatment does not interfere with bathing and the only objection to it is its unsightly color which of course does not pertain in this instance. Another useful prescription is crude coal tar, acetone and flexible collodion in equal parts.

LEUKODERMA

To the Editor—I have a patient with leukodermic spots appearing on various areas of the extremities. He also complains of a continuous mild pain in the epigastrium. Is there any association between the gastric and skin conditions? Please suggest a method of treatment of the skin condition. Give possible causes and prognosis. Please omit name.

M D New York

ANSWER—There is probably no association between the gastric and the skin condition. The cause of the epigastric pain should be ascertained by a careful clinical and laboratory study. There is no successful method of treating leukoderma. Dilute hydrochloric acid has been suggested. Gold sodium thiosulphate intravenously has been used but is not without danger. The cause of the disorder is unknown. Occasionally a familial tendency is noted. A trophoneurosis has been suggested, in view of the association at times with alopecia areata. The prognosis is not good. The patient should keep out of the sun as this intensifies the contrast between healthy and whitened patches.

IMMUNIZATION AGAINST DIPHTHERIA

To the Editor—There has recently been put on the market a single injection alum precipitated diphtheria toxoid which is claimed to give a higher percentage of negative Schick tests with the production of immunity within two months. References are made by the manufacturers to the work of Havens, Graham and Wells in the June 1932 issue of the *Journal of the American Public Health Association* and clinical reports on their work appear in the February, 1933 issue of the *Journal of the Medical Association of Alabama*. In the April 8 issue of *THE JOURNAL* a report by Graham, Murphree and Gill shows that almost 95 per cent were made Schick negative by a single injection. I am writing you to inquire whether or not other authorities consider the work done to date positive enough in results to justify substitution of this single injection toxoid for the two or three injection toxoid or toxin antitoxin mixture heretofore used generally. Since the work is so recent can one be sure of permanent immunity following a single injection? Please omit name.

M D Pennsylvania

ANSWER—Until further use of the alum precipitated diphtheria toxoid has given satisfactory results in the hands of those who are in a position to test it on a large scale it would be wise not to abandon the older satisfactory methods of immunization. The permanence of immunity can be determined only by actual tests but one might expect that this would not be appreciably influenced by the method by which the immunity is produced.

SEROLOGIC TESTS FOR AMEBIC DYSENTERY

To the Editor—I am much interested in the treatment of amebic dysentery and I have heard that a blood agglutination test has been developed for the detection of the presence of *Endamoeba histolytica*. Will you favor me with full information concerning this test and where I shall be able to obtain reprints of articles on this subject?

GUY W. VAN HALTERN, M.D., Dallas, Texas

ANSWER—As far as we know there has been no blood agglutination test perfected for the detection of *Endamoeba histolytica*. Of the various serologic tests that have been tried (a review of which may be found in Tahaferris' "The Immunology of Parasitic Infections," 1929), the best seems to be complement fixation, as used by C. F. Craig (*Am J Trop Med* 9:277 [Sept] 1929). For practical work, however, direct microscopic examination and especially cultivation of stools remain the most trustworthy methods of ascertaining the presence of *Endamoeba histolytica*.

GASTROINTESTINAL INFLUENZA

To the Editor—I should like to be enlightened as to the status of gastro-intestinal influenza. When I was in school not so long ago the professors said that there was no such thing strictly speaking, but that they were cases of food poisoning or gastritis. Private practitioners at that time called intestinal flu any case of abdominal discomfort of unknown etiology. Tidy in his fourth edition says it is rare. The enclosed bulletin of the Louisiana State Board of Health (24:2 [June] 1933) speaks of 190 cases. What is the present status of this diagnosis? Please omit name.

M. D. Louisiana

ANSWER—The term gastro-intestinal influenza is still somewhat vaguely used. There is no evidence that sporadic outbreaks of disease in which intestinal symptoms predominate are due to the infectious agent that causes true pandemic influenza. Many of the occasional outbreaks called "intestinal flu" and similar names have been shown to be various types of gastro-enteritis caused by paratyphoid bacilli and similar organisms. In such an instance as the outbreak of gastric and respiratory influenza reported by Thomas McGowan in Glasgow (*M. Officer* 46:115 [Sept 12] 1931) no convincing evidence is presented that the outbreak was really influenzal in nature. An interesting possibility is suggested by C. C. McLean (*South M J* 24:624 [July] 1931), who believes that the disease known as intestinal influenza in certain localities is a definite entity of unknown etiology. Perhaps the outbreak described in the bulletin sent by our correspondent belongs in this category. It is certainly true that up to the present no definite relation between such outbreaks of gastro-enteritis and influenza has been established.

TINNITUS AFTER OTITIS MEDIA

To the Editor—A patient several months ago had bronchopneumonia followed by a left sided suppurative otitis media for which a myringotomy was done. A seropurulent exudate was drained. Since that time the patient has been complaining of an intermittent ringing and buzzing of the left ear. The examination of the nose, throat and ears at this time is essentially negative. The patient is under continuous treatment but does not seem to get any relief. Do you think that these ear noises are functional or organic in nature? What is the prognosis? What in your opinion is the best treatment? Is psychotherapy indicated? Please omit name and address.

M. D. New York

ANSWER—With tinnitus due to an acute or a subacute otitis media the prognosis is a rule is quite good. It is possible that there is still a small amount of serous exudate in the middle ear, and if so myringotomy followed by a careful inflation of the ear will serve a good purpose. The condition is certainly an organic one and not a functional one. If there is no fluid in the middle ear, careful catheterization followed by the use of a mild sedative such as bromides, will often aid in recovery. In some instances small doses of belladonna are efficacious. The nasopharynx should be carefully examined and if any abnormalities are found which influence the patency and proper aeration of the eustachian tube they should be corrected.

LATENCY OF MALARIA

To the Editor—I have not been able to find an answer in textbooks to the question: Can one who has had malaria, not the tropical type, still have recurrent chills fifteen years later after supposed cure? I have been asked to examine blood smears of patient of this type with no demonstrable signs of malarial parasites. If there is a possibility of the condition to be true, can you suggest a method when the parasite is likely to be seen in the blood?

A. M. O'Brien, San Francisco

ANSWER—The question of how long a malaria infection can remain latent and later relapse is one on which there are comparatively little controlled data and consequently many diverse opinions. In general relapses after seeming cure are least frequent in *Plasmodium falciparum* more frequent in *P. vivax*

and most frequent in *P. malariae*. The question applies chiefly to *P. vivax*. Although some investigators believe there are authentic cases of this infection remaining latent seven or even fifteen years and then relapsing, such occurrences must be rare and most investigators view with suspicion so-called relapses occurring more than three years following cure. If these cases are true relapses it should always be possible to demonstrate the parasites in thick blood films.

ANTUITRIN S—PARKE DAVIS & CO

To the Editor—Parke Davis & Co. of Detroit is putting out a substance named Antuitrin S and the representative in this district has advertised this as containing the ability to check the flow of uterine hemorrhage caused from submucous fibroids of the uterus and any other uterine tumors not malignant. Does the American Medical Association think that this Antuitrin S will relieve the excessive menstrual flow in benign tumors of the uterus that have successive hemorrhages?

S. R. Borkin, M.D., Topeka, Kan.

ANSWER—"Antuitrin S"—Parke, Davis & Co. is said to contain the prolactin principle of Aschheim and Zondek, obtained from the urine of pregnant women. The published evidence indicates that prolactin is of value only in certain cases of functional uterine hemorrhage. The JOURNAL does not know of any evidence that it may relieve hemorrhage due to uterine tumors of any sort, whether benign or malignant. The report of the Council on Pharmacy and Chemistry on "Estrogenic Substances Theelin" (*THE JOURNAL*, April 29, p. 1331) covers this phase of the problem at some length. Antuitrin does not stand accepted by the Council on Pharmacy and Chemistry.

EFFECTS OF EPHEDRINE IN NOSE

To the Editor—Can you advise me as to what possible bad effects might be expected following the frequent possibly daily use of a dilute solution of ephedrine not over 0.5 per cent in liquid petrolatum over a long period of time not only as regards the effect on the membranes of the nose but particularly with regard to any systemic effect? This inquiry is prompted by the question of a patient using such a preparation who had gotten information through lay sources to the effect that ephedrine has effects somewhat similar to cocaine. Please omit name.

M. D. North Carolina

ANSWER—Cocaine is usually classed as a narcotic and has a local anesthetic effect when applied to the mucous membrane of the nose. In some instances in which ephedrine has been used for long periods, individuals have developed a rapid pulse and sometimes a tremor. On the other hand, some persons may use it for a long time without any untoward symptoms. So far as the use of ephedrine in oil on the mucous membrane is concerned it has been stated by some research workers that the oil has a deleterious effect on the cilia, but bad results have not been observed from the use of liquid petrolatum to which a small amount of ephedrine has been added.

RELATION OF MYOCARDITIS AND CORONARY THROMBOSIS TO TRAUMA

To the Editor—A man aged 37 was accidentally struck over the pericardium by a golf ball. He was in a state of shock for fifteen minutes and gradually recovered so that he was able to attend to his business the following two days. On the night of the third day there was an attack of angina pectoris with electrocardiographic evidence of cardiac infarctions. Prior to the chest injury there had been no symptoms of coronary disease. Is it likely that there was a traumatic myocarditis? Can you refer me to some literature bearing on this subject? Please omit name.

M. D. Lincoln, Neb.

ANSWER—Mild infections may predispose to a coronary thrombosis as mild infection of the upper respiratory tract, mild cystitis or some minor ailment, and it is conceivable that the slight accident might have had some bearing on the coronary thrombosis. It is much more likely, however, that it was simply a coincidence.

Traumatic myocarditis is one of those indefinite terms that is best not used at all, and there is no literature of scientific value on the subject.

USE OF VIOSTEROL IN RICKETS

To the Editor—A representative of the Upjohn Pharmaceutical Company made the statement that there had not been a single case of rickets chemical recovery from rickets by the use of viosterol. Is this true or is it just propaganda? Please omit name.

M. D. Indiana

ANSWER—This statement is absolutely without fact. Numerous chemical investigations were undertaken to determine the prophylactic and therapeutic value of viosterol before it appeared on the market. It was found that when this substance was given in adequate amounts it would prevent and cure rickets.

Book Notices

Surgery of the Stomach and Duodenum. By J. Shelton Horsley, M.D. F.A.C.S. LL.D. Attending Surgeon St. Elizabeth's Hospital, Richmond, Va. Cloth. Price \$7.50. Pp. 200 with 136 illustrations. St. Louis: C. V. Mosby Company, 1933.

This monograph presents primarily the knowledge, clinical experiences and opinions of a well known competent gastric surgeon. It reflects the problems that confronted him and provides the ways and means that proved successful in his hands. The work is divided into fourteen chapters. The preliminary four chapters consider the embryology, anatomy and physiology of the stomach and duodenum, the diagnosis of lesions of these structures and a practical discussion of their two chief lesions, namely, peptic ulcer and cancer. Concerning the etiology of ulcer the author shows an increased interest in the neurogenic theory, while of cancer of the stomach he says "One of the ways we can account for the majority of the cases of cancer of the stomach is that they originate from benign lesions or tumors that have given no symptoms until malignancy occurs and is well advanced. By far the greater part of the text is devoted to a rather detailed description of the various surgical procedures on the stomach and duodenum, their indications, technique and complications. The book is beautifully and amply illustrated, concise to a fault at times and is practical. It is recommended to all interested in the subject.

Rheumatismus und Grenzgebiete. Von Dr. Anton Fischer, Oberarzt am Rheumaforschungsinstitut am Landesbad der Rheinprovinz, Aachen. Fachbücher für Ärzte, Band 11. Herausgegeben von der Schriftleitung der Klinischen Wochenschrift. Cloth. Price 18 marks. Pp. 223 with 43 illustrations. Berlin: Julius Springer, 1933.

This is one of a series of small books published apparently especially for general practitioners. The author covers not only diseases of the joints but also diseases of the epiphyses as Perthes', Kohler's and Kienbock's diseases. Included in the joint diseases in addition to rheumatism are discussions of tuberculous and syphilitic lesions involving the articulations. Ten pages is devoted to a discussion of gout. In the first thirty-six pages the author discusses the means employed in diagnosing joint diseases. He emphasizes the importance of the history and describes the method of conducting the physical examination and the value of various serologic and immunologic tests and the interpretation of roentgenograms. His classification of rheumatism is rather confusing, owing largely

to the nomenclature. Unfortunately, in the nomenclature recommended by the International League for the Study of Rheumatism the term "arthritis deformans" in the German classification is synonymous with "osteo-arthritis," while in the English nomenclature this term is synonymous with "rheumatoid arthritis." The author is a physician with a wide clinical experience in this group of diseases and evidently has a good knowledge of pathology. He has compressed a large amount of information in a relatively small volume. The book should be of great value to the practitioner and also to the specialist who desires to have at hand a concise reference book.

Clinical Aspects of the Electrocardiogram Including the Cardiac Arrhythmias. By Harold E. B. Pardee, M.D., Assistant Professor of Clinical Medicine, Cornell University Medical College. Third edition. Cloth. Price \$5.50. Pp. 295 with 74 illustrations. New York: Paul B. Hoeber, Inc., 1933.

The practical aspects of electrocardiography have been treated admirably, with a minimal amount of overlapping of material. From this standpoint the third edition, although making no noteworthy additions over its predecessor published five years ago, is one of the best books written so far for the clinician. Perhaps the best chapter is the fourth, dealing with the electrocardiographic changes in myocardial disease. With the evidence adduced that the leuogram and dexiogram of Lewis cannot be strictly applied to the human electrocardiogram, one finds identical curves in the two editions (fig. 15 in the second and fig. 18 in the third edition) now with the more modern labeling. The significance of a deep Q wave is also discussed. Excellent as the practical substance of this book is, one may also seriously question whether the additions and changes in the theoretical aspects of electrocardiography found in this edition sufficiently warrant a new printing. From the standpoint of theory, notwithstanding the contributions of Craib and Wilson during the last few years and of which mention is made by the author, perhaps little has been added during the past five years that is significant. The meaning of electrocardiographic deflections is imperfectly understood. Physicians not in possession of the second edition of Pardee's book can hardly afford to be without his latest contribution. It is highly recommended.

Human Mentality in the Light of Psychiatric Experience. An Outline of General Psychiatry. By Bror Gadellus. Cloth. Price 33 Danish crowns, 33 shillings. Pp. 620 with 49 illustrations. Copenhagen: Levin & Munksgaard, 1933.

This textbook of psychiatry, originally published in two volumes under the Swedish title *Det mänskliga sjalets*, is intended as a general guide to normal psychology and psychopathology. The author has especially attempted to point out the manner in which normal psychology has been benefited and clarified by psychiatric experience. The book is extremely detailed and copiously annotated. Its scope is large; the subject matter is well chosen and the style is scholarly. There are eighteen chapters grouped into three main sections: (1) the functional structure of mental life and its morbid changes; (2) causes and (3) treatment of mental diseases. The two introductory chapters give a brief survey of the history of psychiatry and a discussion of epistemological points of view or working methods of psychiatry. The eleven chapters in the first section deal with psychologic principles, the morbid changes in the emotional life, philosophical discussion of the ego and its disorders, the abnormalities of memory, thinking and volition and discussions of regression and psychotic symptomatology. The author's approach to these subjects is primarily psychobiologic, though recognition and adequate discussion are given to other schools of psychopathologic thought. The second section discusses causative factors in mental illness under two chapter headings: endogenous versus exogenous causes and influences of heredity. Consideration is given to the psychoanalytic approach, but this is discussed at greater length under a separate heading. The third section, composed of three chapters, is devoted to the principle of modern treatment, an examination of psychoanalysis and a discussion of forensic psychiatry illustrated by numerous citations from Swedish civil and criminal experience.

Students of psychiatry will find the organization of the book somewhat different from the case analysis method commonly used in American textbooks. There is enormous detailed

philosophical discussion, especially with regard to fundamental psychologic principles. The author's dynamic approach is illustrated in the following: "The normal mental structure has its susceptible points, its pre-formed lines of breaking, hence the morbid changes of personality do not set in anyhow and quite capriciously but in a manner determined by the nature of the mental functions." In spite of the abundance of reference and illustrative material, the clinical approach seems unsatisfactory. Noticeably lacking is any thorough discussion of the neuroses, a symptom complex receiving more and more attention in medical education. The section on treatment does not seem adequate for clinical usage and consistently emphasizes the institutional therapeutic method and program. Freudian psychoanalysis is attacked as unstable, inadequate and highly fantastic, and Freud is personally discredited. The book is of definite value to the psychiatrist and stands as a monumental compilation of data and references to continental literature. For those who are in search of a complete usable textbook for psychiatric teaching the book would seem too involved. The illustrations are well chosen.

The Story of Childbirth. By Dr. Palmer Flindley. Cloth. Price \$3. Pp. 376 with 124 illustrations. Garden City: Doubleday, Doran & Company, Inc. 1933.

This book has an attractive appearance and a good name as author. Apparently it is intended for laymen. It is a collection of pictures, anecdotes and historical references to customs and taboos of childbirth, there are discussions on the maternal impression theory, on sterility and fertility, on abortion, a chapter on dystocia among the savage tribes thoroughly, if not politely illustrated, the history of the midwife and trained nurse and a well deserved appreciation of Mary Breckinridge's "Frontier Nurses", a history of gonorrhea and syphilis and their effects on the human race, with much moralizing, a history of anesthetics, and a history of puerperal infection. Poor Ignaz Philip Semmelweis—he is here rechristened Emil! The usual indefensible statement is made that the United States is the worst place in the civilized world for a woman to have a baby, and—unfairly—the statistics of the various countries, which, all serious students of the situation decide are not comparable, are repeated again in an attempt to prove it. The chapter on prenatal and postnatal care is good, but does it belong? Does the "monkey trot" really prevent displacements? There is a good chapter on birth control and abortion, a chapter on dress and maternity, interesting if not instructive, a chapter on embryology and the anatomy and physiology of pregnancy and labor, a chapter on the 'Lost Art of Obstetrics' which is a tirade against forceps and cesarean section in which good and bad and irrelevant are mixed with numerous malappropriate pictures. Such a chapter (like several of the others) is more likely to destroy confidence in the profession than to restore the Lost Art. What is the "art of obstetrics"? Finally there is a chapter on the modern maternity hospital.

Recherches personnelles pour servir à l'étude de la gonococcie. Par A. Guepin. Paper. Price 30 francs. Pp. 218. Paris: Les Presses Universitaires de France. 1933.

Guepin presents an interpretation and clarification of the problem of gonococcal infection based on extensive experience and investigation. He deplores the confused state of knowledge and lack of interest in this infection the consequences and disastrous end-results of which are frequently minimized. He conceives gonorrhea to be a deep seated infection of the genital tract with a tendency for the gonococcus to persist and multiply in the tissues. There is no definite termination to the infection which progresses until it exhausts itself. Too much emphasis is placed on the urethral discharge. The abundance or scarcity of urethral secretions is no indication as to the severity or mildness of the infection, in the author's experience. The gonococcus may gradually be altered by the reaction of the tissues. In 1907 Guepin first emphasized the necessity for cultural studies of gonococci in the secretions and since then he has been an ardent advocate of spermoculture in diagnosis and treatment, especially in patients contemplating marriage. The cytology of the prostatic secretions is discussed and the importance of this method of studying the deeper gonococcal infections is emphasized. There are many gonococcus carriers whom Guepin classifies as convalescents, chronic carriers and

healthy carriers. He was able to demonstrate virulent gonococci in 70 per cent of men and 80 per cent of women supposedly cured clinically. The history and technic of spermoculture are discussed in detail. The author is pessimistic about abortive treatment. The cessation of discharge under chemical applications is no indication of cure. The use of irrigation with dilute solutions of antiseptics is recommended. The author has obtained the same results with 8 per cent solution of sodium chloride as with strong silver protein, mild silver protein or potassium permanganate. The technic and indications for prostatic massage are described. This monograph is a stimulating discussion of the entire question of gonococcal infection. It is replete with original concepts based on extensive work in this field.

Nervous and Mental Diseases for Nurses. By Irving J. Sands, M.D., Associate in Neurology, Columbia University. Second edition. Cloth. Price \$1.75. Pp. 281 with 19 illustrations. Philadelphia & London: W. B. Saunders Company. 1933.

This work has already proved its worth as a textbook. The greater part is occupied by succinct descriptions of the various neurologic and psychiatric disease entities, described in such a way that they can be recognized but not in greater detail than would be needed in the instruction of nurses in either a general or a psychopathic hospital. These descriptions are introduced by elementary chapters on neuroanatomy, endocrinology and psychology. One questions whether these are complete enough to make the later clinical material any clearer. The chapter on the development of modern psychiatry might better be placed before the section of the book that describes psychiatric disorders. The chapter on mental hygiene is sufficient to give nurses a smattering of a subject concerning which they are likely to hear much, and those parts of the book dealing with nursing procedures, although much abbreviated and omitting discussion of note making, would seem to present a good deal of accurate information. The advisability of including such a brief chapter on psychoanalysis (new in this edition) must remain in doubt. It is too terse to give a real understanding of the subject and cannot in such a brief space, adequately prepare the nurse to continue studying the subject. The book should be helpful to those who must assign a simple book on nervous and mental diseases to their student nurses, but for those who are teaching advanced psychiatric nursing it leaves much to be desired.

Die Histopathologie der Uterusmucosa. Ein Leitfaden für Gynäkologen und Pathologen bei der histologischen Diagnostik. Von Dr. H. T. Deelmann, ord. Prof. der allgemeinen Pathologie und pathologischen Anatomie der Reichsuniversität Groningen. Paper. Price 22 marks. Pp. 247 with 248 illustrations. Leipzig: Georg Thieme. 1933.

This book is dedicated to the needs of the laboratory examiner who is confronted with the often difficult task of making a reliable diagnosis from scanty scrapings. It is a serious attempt to be a guide in difficult diseases. Particular emphasis is laid on changes in the uterine mucosa occurring during normal and complicated pregnancy. Probably the characteristic feature of this book is the approach to the subject. After a few theoretical and practical considerations at the beginning of each paper the author gives a series of concise case reports, including only the relevant histories, a short follow-up study, and a microscopic description of the scrapings with photomicrographs. A whole section is devoted to atypical changes in the uterine mucosa which may be confused with early carcinoma. The term "malignant adenoma" is not approved because it merely indicates that there are instances of carcinomas of the uterus showing little atypical cellular change. The point is stressed that difficulties may arise from the fact that the structure in a given uterine carcinoma may vary in various sections. Such structural differences are much greater in uterine carcinomas than in most other carcinomas. A series of cases is included with the relevant histories and microscopic pictures of the curettings which are not definitely diagnosed as carcinoma and from which the conclusions must be drawn that the question "malignant tumor or benign hyperplasia" or "benign tumor" cannot always be answered. The illustrations with the exception of two are photomicrographs and most of them are excellent. Both the pathologist and the gynecologist will find this book useful, the pathologist because of the micro-

scopic features and the differential diagnostic points, and the gynecologist because of the case histories and the correlation between clinical and histologic observations. The book also will make the clinician realize the difficulties the pathologist is often confronted with in diagnosing scrapings and will teach him not to expect miracles from the morphologist.

Sindromi oculo simpatiche Da Enrico Morelli. Paper. Price 40 lire. Pp 461 with illustrations. Pisa. Casa editrice Giardini. 1933.

The title is misleading, since one would expect to find the book limited to ocular disturbances of neurogenic origin, whereas it is a mine of concise and authentic information on the anatomy, physiology and clinical pathology of the vegetative nervous system. In the first part the author has written interestingly on the history, embryology and anatomy of the vegetative nervous system describing the interrelationship to the chromaffin system. Several fine illustrations help to make the text interesting. In the second part there are thirteen chapters dealing with the physiology of the vegetative nervous system. The functional relationship between the parasympathetic and the sympathetic division is well discussed. Then a general review is made of the sympathetic syndromes and of the humoral influences, also the relationship to endocrine disturbances and vitamin deficiencies affecting the vegetative nervous system. The third part deals again, from a general standpoint, with the symptomatology of disturbances of the parasympathetic and sympathetic system, and reviews existing pharmacologic knowledge of the various drugs affecting the function of the system. It is only in the fourth part of the book that the author takes up the various ocular syndromes connected with the vegetative nervous system. He discusses the various angiospasm of the eye, glaucoma and the pharmacology of drugs influencing the course of the disease. The sympathetic in relation to glaucoma is fully discussed in connection with theory of the neurogenic origin of this disturbance. The last chapter deals with the interrelationship of vegetative disturbances due to infection of the sinuses, ear and nose.

Frontiers of Medicine By Morris Fishbein M.D. Editor. Journal American Medical Association and Hygeia the Health Magazine. A Century of Progress Series. Cloth. Price \$1. Pp 207. Baltimore. Williams & Wilkins Company in Cooperation with the Century of Progress Exposition. 1933.

A Century of Progress series consists of small books by well known writers on the fundamental sciences on which is based the development that has led to modern industry. In this series the progress of medicine is represented by the present volume. The narrative follows in the main the chief epochs in medical history before Hippocrates from Hippocrates to Galen the middle ages, the revolt against dogmatism, the foundation of anatomy by Vesalius and of physiology by William Harvey, the development of clinical medicine begun by Sydenham, Pasteur and the microbic era, and the modern period. "An attempt has been made, by occasional use of narrative forms to add interest to what would otherwise be merely a list of names and dates." In this attempt the author has succeeded well. The tale is told in readable and interesting fashion. The book deserves to be read widely, and physicians would do well in recommending it to all persons who may be interested in a brief but graphic account of the development of medicine.

Vitamin A Content of Foods and Feeds By G. S. Fraps and Ray Trechler. Division of Chemistry. Texas Agricultural Experiment Station. Bulletin No. 477. Agricultural and Mechanical College of Texas. Paper. Pp 34. College Station. Brazos County. Texas. 1933.

The bulletin briefly summarizes the significance of vitamins A, B, C, D, E and G and gives in detail the method of estimating vitamin A activity. Tables give the vitamin A content expressed in units of foods and feeds investigated by the Texas Agricultural Experiment Station and as reported in the literature. Sections of the report are devoted to factors that affect the vitamin A activity of foods such as drying or curing, canning, heredity and the stage of growth and the effect of vitamin A in food on the vitamin A content of milk, butter and eggs. The cost of vitamin A activity in human food and the quantities of vitamin A required by animals and man are touched on. The bulletin is of exceptional value to all concerned with the vitamin A content of foods in the dietary.

Gynécologie opératoire Par Henri Hartmann professeur honoraire de clinique chirurgicale à la Faculté de médecine de Paris. Second édition. Paper. Price 110 francs. Pp 585 with 478 illustrations. Paris. Masson & Cie. 1933.

Professor Hartmann has produced an operative gynecology that should be of real value to American gynecologists and general surgeons who perform gynecologic operations. The text is clear and concise. The illustrations, a considerable number of which are of instruments, are well reproduced and may be easily understood by the trained surgeon. Among the procedures not commonly shown in American works are operations on the pelvic sympathetics for dysmenorrhea and other types of severe pelvic pain. The work contains a fairly complete discussion of diagnostic methods and minor therapeutic measures in the first part. This is of interest in that it illustrates certain variations of methods one finds when visiting clinics in various parts of the world. While French gynecology may differ from American practice, readers in this country may find many useful suggestions from a close study of principles employed in Professor Hartmann's clinic. The publishers apparently have considered the reduced finances of the average physician, since the work has been bound with an attractive paper cover and is printed on good but inexpensive paper. This has made it possible to offer an unusually worth while work at a low cost.

Medicolegal

Silicosis. Compensability under Workmen's Compensation Act (California), When Right to Compensation Begins.—The Spicky Polish Corporation, in the manufacture of silica powder for commercial purposes, ground silica rock into a very fine powder. Marsh, Lange and Woods, while employees of the corporation, were engaged in the process and took part in sacking the product. Marsh's last day of service was Feb 13, 1928. He died, Feb 14, 1930. His widow filed her claim for death benefits, under the workmen's compensation act, Oct 20, 1930, alleging that his death was due to silicosis contracted in the course of his employment. Woods last worked on Aug 3, 1929. He died, Aug 10, 1929. His widow filed her claim for death benefits, Oct 20, 1930, attributing death to silicosis. Lange last worked on June 8, 1928, and filed his application for disability payments, Oct 20, 1930, naming silicosis as the cause of his disablement. The industrial accident commission held that no occupational injury could have occurred after the last day of the employee's service and that for the purpose of the act the date of injury was the day on which that service terminated. The commission rejected all three claims on the ground that each was barred by the lapse of time under the provisions of the act. The claimants contended however, that the date of injury was the date when a medical practitioner could determine the nature of the disease from which the employee was suffering, and appealed to the court of appeal. At the request of the justices of the court of appeal the causes were transferred to the Supreme Court of California for determination. That court adopted practically in its entirety an opinion prepared by an acting justice of the court of appeal, Johnson.

An occupational disease, said the Supreme Court, is not classed as an accident but as an injury. Under the workmen's compensation act, proceedings for the collection of disability payments must be begun within six months from the date of the injury and proceedings for the collection of death benefits must be begun within one year from the date of death. In such an occupational disease as silicosis the exact date of origin cannot be determined. It is the cumulative effect of exposure day after day that produces the injury. Because injury in the statutory sense is referable to a period of time rather than to a point in time some rational norm must be adopted for determining the date of the injury as a basis for the determination of the statutory period of limitation for the filing of claims. For purposes of compensation an injury dates from the time when the disease condition causes an incapacity for work. It is then that the employer's liability becomes fixed,

for until then the workman had received no injury in the legal sense, even though the seeds of the injury lodged in his body long before. A latent and progressive disease may not culminate in disability until a considerable period after employment has terminated. If the disabling result is delayed, the injury is correspondingly delayed, and the right to compensation does not accrue until disability occurs.

In the case of a latent and progressive disease, such as pneumoconiosis it cannot reasonably be said that the injury dates necessarily from the last day of exposure to a dust-laden atmosphere. The date of the injury should be deemed the time when the accumulated effects culminate in a disability traceable to the latent disease as the primary cause, and when, by the exercise of reasonable care and diligence, it is discoverable and apparent that a compensable injury was sustained in performance of the duties of employment. To justify an award for disability or death on account of an occupational disease, there must be established an unbroken causal connection between the injury and the employment, or the condition under which the employee is required to carry on his work. When such an unbroken chain of causation is found to exist, all physical consequences flowing from the disease or injury are proper elements for consideration in determining the merits of a claim for compensation or death benefits.

In the case of Woods, application for death benefits was not made until after more than a year after his death and the industrial accident commission properly denied relief. In the case of Marsh, while the application for death benefits was filed within the prescribed time after death the industrial accident commission held that death did not occur within one year after the date of the injury, as was necessary under the workmen's compensation act to entitle the widow to death benefits. The Supreme Court pointed out, however, that in reaching its conclusion in this case the industrial accident commission fixed as the beginning of the prescribed one year period the date when the deceased was first disabled and not the date when silicosis was or should have been diagnosed as the primary and efficient cause of the disability. The order of the industrial accident commission in this case was therefore annulled and the case remanded with instructions to ascertain when the prescribed period of limitations began to run in accordance with the rule laid down by the court. In the Lange case, the industrial accident commission made no finding as to the date when silicosis should or could have been discovered as the efficient and primary cause of his disability, and the evidence failed to disclose sufficient data to justify a conclusion as to when a causal connection between the occupation and the disability of Lange was or should have been discovered. This case also was remanded for further consideration.—*Marsh et al v Industrial Accident Commission of California (Calif)*, 18 P (2d) 933

Silicosis Duty of Employer at Common Law—In selecting instrumentalities for the protection of his employee, such as the instrumentalities necessary for the adequate ventilation of his plant, an employer is required to use only "reasonable care." At common law, says the U S circuit court of appeals, third circuit, citing *Hawes v Spencer* 167 F 266, "The employer is not an insurer, and the duty imposed upon him is not to furnish the safest or newest and best machines and appliances, but only to exercise due care to provide those which are reasonably free from danger." Negligence cannot be imputed to an employer who provides machines and appliances such as are generally used in his line of business. The appellee, Butler, claimed that he had contracted silicosis because of his employment with the appellant company, engaged in grading and pulverizing sand. He charged that the company had failed to use reasonable care to provide a proper ventilating system in its plant to provide him with proper masks, and to give him warning of the dangerous character of his work. There was impressive evidence at the trial, however, said the circuit court of appeals that Butler's employer had installed the most modern and efficient ventilating system available one that was superior to similar systems in the majority of industries like that which the employer operated. No evidence was offered by Butler to show that a better system was available and that his employer, in the exercise of reasonable care,

should have known of the existence of such a system and acted on that knowledge. The company had supplied Butler with a so called Willson sponge mask three months after he entered its service, but Butler contended that it should have furnished a better mask perhaps an air line mask, although the testimony for both parties was that masks of that character were still in the experimental stage and not in general use in the industry. A master, said the circuit court of appeals, must instruct and warn his servant as to dangers of which the master knows or ought to know and of which he knows or ought to know his servant is ignorant. But there was direct evidence that in the present case the defendant and his agents did warn Butler. The act of supplying masks constituted in itself such a warning.

Butler complained that his employer did not warn him of the disease-producing effect of the inhalation of silica dust, but even if this is true, it was not certain said the court, that the employer knew that disease was liable to follow or that he should have known of it in time reasonably to warn his workmen. No evidence was adduced by Butler to show that silicosis normally follows exposure to silica dust or to show what conditions produce the disease, or how long the disease takes to develop. The court found it difficult to believe that an employee of normal intelligence who works in dust has to be told that the inhalation of dust of any kind in large quantities is injurious. When such an employee is handed a mask and put to work with other men wearing masks, in a place equipped with artificial ventilators, that is a plain enough warning that dust is deleterious.

The judgment of the trial court in favor of Butler was reversed and the case remanded.—*Pennsylvania Pulverizing Co v Butler* 61 F (2d) 311

Evidence Presumption that Woman Is Capable of Childbirth Not Absolute—The presumption, said the United States court of claims, that a woman is capable of giving birth to issue so long as she lives is not absolute. Evidence may be received to show that a woman of 50, who seven years previously had her uterus, both fallopian tubes and both ovaries removed, is incapable of bearing children. Such evidence is admissible and is sufficient to overcome the presumption that she is capable of bearing issue.—*Provident Trust Co v United States* 2 Fed Suppl 472

Workmen's Compensation Acts Compensability of Pneumonia—In the course of his employment, a carpenter spent about an hour in a refrigerating room in which the temperature was from 10 to 20 degrees below zero. He developed pneumonia and died. His widow claimed compensation under the workmen's compensation act of Pennsylvania. The sole question to be determined, said the Supreme Court of that state when the case came before it on appeal, is whether death was caused by an 'accident' within the meaning of the act. The exposure, said the court, was not an accident. The ensuing chill was not a sudden and unexpected event a mere chance or contingency. It was a natural and usual consequence of entering and remaining so long in a room with a temperature from 10 to 20 degrees below zero. Compensation was therefore denied.—*Lacey v Washburn & Williams Co (Pa)*, 164 A 724

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to *THE JOURNAL* in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Cancer, New York

18 535 802 (July) 1933

- Relation of Heredity to Cancer Occurrence as Shown in Strain 73 Studies in Incidence and Inheritability of Spontaneous Tumors in Mice. Thirty Second Report. Maud Slyc. Chicago—p 535.
Influence of Hormones on Growth of Carcinoma Sarcoma and Melanoma in Animals. K. Sugura and S. R. Benedict. New York—p 583.
*Primary Osteoid Chondrosarcoma of the Lung. Report of Case. E. B. Greenspan. New York—p 603.
*Primary Carcinoma of the Ileum. J. M. Lynch. New York—p 610.
Exostosis of Mandible of Chicken Complicating Edema of the Wattles. G. M. Smith. New Haven, Conn.—p 616.

Osteoid Chondrosarcoma of Lung—Greenspan presents the history and necropsy observations of a case of primary osteoid chondrosarcoma of the lung in a woman of 35 arising from the bronchial mesodermal tissue. Clinically, the case is of interest because of the gradual occlusion of the main pulmonary artery, which caused progressive heart failure and a relative compensatory polycythemia. Chondrosarcoma metastasizing to the lung is not uncommon, but there was no suspicion throughout the entire course of the patient's illness of a new growth in any other region of the body, and necropsy did not reveal any other tumor that could have been regarded as primary.

Carcinoma of Ileum—A case of carcinoma of the ileum is reported by Lynch in a woman aged 32 who is apparently well six years after radical operation. There was sufficient clinical and radiologic evidence to warrant surgical intervention one year before the actual operation. The growth was much more extensive on the peritoneal than on the mucosal aspect of the ileum, recalling the well known fact that the size of a cancer of the rectum, as seen through the proctoscope is no criterion of its extent through or beyond the intestinal wall. The presence or absence of obstruction governs the procedure of treatment. If obstruction is present, therapy should in the first instance be directed to its relief. Here the intravenous administration of sodium chloride solution is of value. Thereafter enterostomy is of primary importance and may in suitable cases be combined with exteriorization of the affected loop in the first stage of a resection of the Mikulicz type. In the absence of obstruction, immediate resection of the affected loop if possible, should be done followed by a suitable anastomosis.

American Journal of Clinical Pathology, Baltimore

Selecting Bacteria for Vaccines—Solis Cohen studied eighty-four organisms, sixty three that grew in the patient's blood and twenty one that did not. He observed that there is practically no difference between the reactions produced by intracutaneous injections of organisms that grow in the patient's fresh whole coagulable blood and the reactions produced by

organisms that are killed by his blood. There seems to be no correspondence between the absence of bactericidal power in the blood of the host against a given organism and the production in that host of a positive reaction by the intracutaneous injection of such an organism. There probably is no relationship between hypersensitiveness in the host to the exogenous and endogenous toxins of a given organism and the pathogenicity of such an organism for that host. It is questionable whether intracutaneous tests can identify, in a mixed culture, the bacteria that are infecting the patient. Therefore intracutaneous skin tests are probably unreliable for selecting bacteria in the preparation of vaccines.

Flocculation of Diphtheria Antitoxin—The laboratory observations of Anderson and his associates show that (1) the flocculation value of a 2½ year old toxoid does not always correspond to the value established by animal tests but may give a low flocculation value and yet be of satisfactory antigenic activity, (2) the flocculation of a fresh toxin may also show occasional irregularities with high flocculation value and lower toxicity than expected according to the flocculation test, (3) precipitation of extracts of diphtheria bacilli readily takes place with homologous serum, often simulating a true flocculation and (4) toxin broth that accidentally had become contaminated during the production of diphtheria toxin showed higher flocculation values than the uncontaminated flasks. In view of these facts and as elutions of toxoid precipitates by disodium phosphate gave too high flocculation values, as floccules largely consist of magnesium ammonium phosphate, as pyrophosphates are present in meat and bacteria, and as pyrophosphates will flocculate with magnesium compounds, the authors carried out a number of flocculations to determine the influence of the pyrophosphates on the flocculation values. Diphtheria toxins, toxoids and antitoxins and different proteins have been mixed with sodium pyrophosphate, with magnesium sulphate and with colloidal magnesium and have been flocculated according to Ramon's method. They found that phosphates and pyrophosphates may under certain circumstances enhance the flocculation reaction of diphtheria toxin and antitoxin. This enhancement is expressed by an increased flocculation value and a decreased flocculation time. The flocculation reaction consists possibly of interlocking reactions of inorganic constituents of the toxin and serum of bacillary lipoproteins or nucleoproteins and serum precipitins, and of toxin and antitoxin. Flocculation may be a simple neutralization of toxin or toxoid and antitoxin, or it may be a combination of neutralization and a nonspecific reaction or a nonspecific reaction alone. The flocculation reaction is not always specific and therefore is not always a true measure of the antigenic value. The flocculation time is not always a true measure of avidity as determined by flocculation.

Frozen Vegetables—Straka and James examined seventy-two glass containers of frozen peas, twenty-four un inoculated, twenty-four lightly inoculated and twenty-four heavily inoculated with toxin (*Clostridium botulinum*). No toxin developed

in peas that were examined immediately after defrosting, and none developed in those defrosted and kept in the icebox for three days. Toxin was obtained from the spoiled peas in one of the twenty-four un inoculated containers, and botulinus cultures were recovered from eight. The spoiled contents of three of the twenty-four lightly inoculated containers were toxic and cultures were obtained (presumptive identification) from eleven. The twenty-four heavily inoculated containers showed five to be toxic after spoilage, and the organism was recovered (presumptive identification) from every container. All the toxic containers showed type B toxin. Of the organisms recovered from uninoculated containers, seven were type A and one was type B.

Fractures of the Femur—Ilievitz believes that his experience with thirty-six cases of fracture of the neck of the femur, fifty-five intertrochanteric fractures, twenty-three fractures of the shaft and six of the lower end of the femur, with only one death on the second day of admission to the hospital, endorses the statement of Champagniere that more people die from immobilization than from injuries. Of the patients 80 per cent ranged between 65 and 93 years of age, the remaining 20 per cent being between the ages of 1 and 65. For the past seven years the author has used no anesthetics in any case of fracture of the shaft or of the upper and lower ends of the femur. By the utilization of his modified Bohler sling there was no necessity for plaster casts, skeletal traction, open operation, traction by means of weights, special tables, or plaster room and the patients could be treated at home as well as at the hospital. There was not a single case of nonunion in spite of early weight bearing nor were there any deaths due to pneumonia with the exception of the one death in a woman 79 years of age admitted in a moribund condition with multiple ailments.

Fracture of the Patella—Gatewood states that there is no fracture which lends itself to open reduction more uniformly than complete fracture of the patella. Frequently, however, the general condition of the patient or some local complication makes operative reduction inadvisable; therefore he has devised a closed method, the principles of which are well established. In a case of infection in which it was necessary to resort to some closed method of treatment which would permit frequent changes of the dressings of the prepatellar region, a piece of moleskin adhesive 6 by 8 inches was prepared by fastening a

1 inch strip of heavy cardboard to one of the longer margins and setting into it several shoehooks, about five eighths inch apart. The adhesive was applied over the lower part of the thigh just above the infected area. The leg, fully extended, was encased in a cast. A large rectangular window was made in the patellar region. Similar hooks were attached to two other pieces of adhesive, which were incorporated in the cast just below the knee. Finally, strong rubber bands were strung between the upper and lower hooks. These kept the dressing in place and maintained sufficient tension to overcome contraction of the quadriceps extensor. They were tightened as often as necessary to keep up the tension. Although the method was primarily planned to prevent separation of the fragments until the infection had subsided, the result was so satisfactory that the method was continued for six weeks, after which active and passive movements were instituted.

Schilling Hemogram—According to Eisenberg and Nemens the main practical feature of the Schilling count is the recognition of the nonsegmented neutrophil cell, which normally constitutes from 4 to 8 per cent of all leukocytes. If an infection is progressing, the most dependable hematologic sign is the increase in the percentage of the band cells regardless of whether the total leukocyte count and the total neutrophil count rise or not, if the two latter counts are also high, it is a more favorable sign than when they are low, as this would point to the exhaustion of the hematopoietic activity of the bone marrow. In other words, the steady rise of the band cells points to an invasive, progressive nature of the infection, to pus formation and, if postoperative, to an unfavorable termination if they rise during an "uneventful" convalescence, medical or surgical, a complication or a recrudescence is present, regardless of the clinical appearance, since the latter may be delayed hours or days as compared with the rise of the band cells, e.g., an abscess formation following an operation, empyema following pneumonia, or acute exacerbation of a chronic mastoiditis. When such a rise in the band cells is accompanied by a fall of the total white blood cell or neutrophil count, or both, its unfavorable significance is greatly enhanced. The authors have seen central deep-seated pneumonias, retrocecal appendicitis and other "atypical" infections giving a typical hematologic picture days before they became "typical" clinically. They point out that the Schilling count is the ordinary blood count, except that the immature neutrophil cells are separated from the segmented or mature neutrophils and that the presence of occasional metamyelocytes or myelocytes should not be ignored, as it usually is in nonleukemic cases, but should mean an even greater danger than the rise of the band cells, the more immature the blood cells, the more severe the infection.

Ventral Hernia—Farmer describes a method for the repair of ventral hernia which is founded on a true anatomic basis. He has used fascia both living and dead, of varied sizes and shapes in varied ways in hernioplasty and has had opportunities of viewing the results. His conclusions are that large fascia strips of living structures do not become vivified. This is more obvious when the strip, whether living or dead, is not placed so that every centimeter is in close contact with living tissue having ample circulation. He has also observed that the results are more favorable when the strip is inserted deeply with tension through the tissue rather than being sutured in place on the surface. The recurrence is less frequent and the number of operable cases increased. In the postoperative care one need not be concerned about the tension on the suture line, abdominal binders are not needed and the patient is more comfortable. This method is founded on a true anatomic basis. If the patient is obese, it is advisable to make a large transverse incision, remove the portion of skin and subcutaneous fat and then make the incision through the muscle in the median line. When the sac is small it may be readily excised, the peritoneum sutured, the edges of the muscle thoroughly cleansed and brought together, and then an overlapping closure of the external sheath of the rectus can be made. If the hernia is large and the muscles are widely separated, an imbrication of the peritoneum and fascia is necessary, a plastic closure of the Mayo type bringing the cleansed peritoneum over the scarified fascia or rectal sheath. Much tension is required to cause the edges to overlap and it is here that strips of ox fascia placed transversely are of the greatest benefit. When the sac contains omentum

or intestine with numerous adhesions, it is well to enter the peritoneum above the sac, to insert the index finger into the abdominal cavity and with the finger as a guide carefully to dissect the rim of the sac on one side. The skin and subcutaneous tissue covering the sac may then be lifted and the dissection completed without injury to the intestine. It may be advantageous to leave parts of the parietal peritoneum attached to the intestine. In patients in whom the surgical risk is uncertain it is expedient to place strips of ox fascia to strengthen the fascia and muscle layers and partly reduce the defect in the first operation. The second stage consists of dissection of the layers and an overlapping procedure.

Neurosyphilis—Hopkins discusses the various forms of neurosyphilis in about 1200 patients, 200 of whom died while under observation and 480 of whom were observed for more than two years before lapsing. In early neurosyphilis the best method of treatment was an intensified form of routine antisyphilitic treatment with arsphenamine. In diffuse late neurosyphilis routine antisyphilitic treatment was much inferior to treatment with arsphenaminized serum subdurally administered triparanide or malarin. The serum gave the best results but those given by triparanide were almost as good and, owing to the much larger number of patients treated with it, the results probably represent a more nearly exact comparative estimation of its value. Malarin was the treatment of choice in dementia paralytica and dementia paralytica with tabes. In tabes the best results were obtained with malarin although those receiving triparanide did almost as well and both types of therapy were far superior to routine treatment. Treatment with subdural injections of arsphenaminized serum was successful in arresting the process in numerous cases of optic atrophy which was advancing in spite of routine methods of treatment. The number of patients with purely vascular neuro-

syphilis was too small for analysis. The correlation between the clinical and the serologic improvement is roughly proportional to the duration and type of pathologic involvement. In early neurosyphilis, absolute agreement is found in a high proportion and in parenchymatous neurosyphilis in a correspondingly low proportion, of patients under treatment.

Sodium Nitrite—Weiss and Ellis studied the effect of large therapeutic doses (from 1 to 5 grains [0.065 to 0.95 Gm]) of sodium nitrite by mouth on ten normal persons on twenty-nine patients with primary arterial hypertension on five with glomerulonephritis and on nine in whom unilateral nephrectomy had previously been performed. The nitrite constantly produced symptoms of increase in cardiac rate and depression of blood pressure and renal function. No simple correlation was found between these factors except when they were markedly altered. A decrease of systolic blood pressure was the most frequently observed effect of sodium nitrite. This was caused probably by dilatation of certain parts of the arterial system. The greater the initial degree of arterial tonus the greater was the drop in systolic pressure. With arterial hypertension this was particularly evident. In five normal persons, sodium nitrite produced no change in the minute volume output of the heart. In five patients with arterial hypertension, this output was doubtfully reduced in three and reduced 15 and 32 per cent respectively, in two. In nine of these ten subjects there was a reduction of the cardiac stroke volume output, which reached 15 per cent or more in six. Sodium nitrite did not affect the basal metabolic rate of nine of the ten subjects, it possibly increased the rate in one. The effect of the nitrite on renal function was investigated thirty-five times by simultaneous determinations of the urinary output and urea and creatinine clearance tests. In no case was the renal activity improved. In fourteen instances there was no change in renal function, thirteen times it was definitely decreased, and on eight occasions it was questionably lowered. The authors discuss and correlate the physiologic changes that occur in the human cardiovascular system as a result of the action of sodium nitrite. They believe that the use of sodium nitrite in the routine treatment of arterial hypertension with the hope of maintaining the blood pressure at a relatively low level is illogical and may be dangerous.

Blood Cultures—Friedberg made 103 blood cultures for seventy-seven patients suffering from a variety of febrile illnesses suggesting the presence of bacteremia. Simultaneously, flasks containing K medium were inoculated with blood from these patients. The K medium showed 4 per cent less positive results than the ordinary routine method. Compared with the individual flasks and plates used in the ordinary method the flask of K medium showed slight inferiority to some and slight superiority to other individual units. Other disadvantages were found in the difficulty and expense of preparing the medium and the greater time necessary before an organism could be identified. Repeated subcultures from the original K flask failed to show any invisible filtrable forms that could be converted to the ordinary state by transfer to solid medium as alleged by Kendall. There was no evidence in the cases studied to show that the clinical picture was due to a filtrable invisible form of an organism that did not show itself on the ordinary mediums. In several instances common organisms were found to pass through the Berkefeld filter suggesting the possibility that the K medium may have had some influence in impairing the efficiency of the filter.

Function of Liver—Ricketts performed the modified dextrose tolerance test of the function of the liver as described by Althausen Gunther, Lagen and Kerr on ten patients who were considered to have normal livers at the time of examination and on four patients with frank hepatic disease. Of the ten normal patients nine responded to the test by a drop in blood sugar to points considerably below the critical level for normal reactions and showed symptoms and signs of hypoglycemia. Of the four patients with frank hepatic disease three responded by definite chemical and clinical hypoglycemia. There was no essential difference between the behavior of the normal and the abnormal groups. The author suggests that the modified dextrose tolerance test in its present form is not a satisfactory measure of the metabolic function of the liver.

Benign Tumors of the Tonsil—Hara mentions as benign growths of the tonsil papillomas, angiomas, lymphomas adenomas, fibromas, lipomas, chondromas, teratomas and various forms of mixed tumors and states that the tonsillar fibroma may be sessile or pedunculated. In the series that he reviews, seven tumors originated on the right and fourteen on the left tonsil, and in five cases there was no statement as to the site of attachment. The patient in whom these tumors appeared were of various ages. The patient in the case that he reports was the youngest, being $7\frac{1}{2}$ years. The color of the tumor is a pale pinkish rose. Its consistency is normally hard and woodlike. The diagnosis offers no difficulties. The prognosis as to life is excellent. The rational method of treatment is the surgical removal of the tumor.

- *Congenital Valves of Posterior Urethra in Twins I Davidsohn and C Newberger Chicago—p 57

Trauma and Encephalitis—Rosenthal reports three cases, in children of one family, in which the relation of injuries sustained at birth to encephalitis is demonstrated. He suggests that many of the idiopathic and atypical forms of encephalitis in children are due to the superimposition of a mild infection or intoxication on foci of lowered resistance in the brain, secondary to insults sustained at birth. He explains colloid deposits and deposits of calcium in the brains of children as sequelae to injuries sustained at birth. One of his cases showed an inflammatory process while the other two showed toxic

ones superimposed on traumatic lesions sustained at birth. The attacks (transient paralysis, vomiting, mental disturbances), demonstrate the susceptibility of the brains of such persons to infections and toxic irritants.

Valves in Posterior Urethra in Twins—Davidsohn and Newberger observed identical valves in the posterior urethra in twins. They produced an obstruction to the urinary flow, with the usual clinical and anatomic consequences. The clinical picture and the pathologic changes were identical in these twins. The authors suggest the term "pericollicular valves," with an anterior and a posterior subvariety, to replace types I and II of Young's classification. They base the modification on the apparent anatomic and suggestive embryologic relationships to the colliculus seminalis.

- Relation of Trauma to Rupture of Hollow Abdominal Viscera J V Reed Indianapolis—p 216

Epidermoid Cysts of the Spleen—Shawan states that only four reported cases of epidermoid cysts of the spleen and one unpublished case recalled by Lubarsch have been described in young people. Sex seems to play no especial part as two occurred in boys and two in girls. Complete and repeated microscopic examinations of all splenic cysts may add to the number of these epidermoid cysts. Tumor and distress in the splenic region coupled with elimination of other tumors by various clinical methods especially roentgenoscopic studies, facilitate the correct diagnosis of large splenic cysts. Splenectomy, the most satisfactory treatment in large unilocular cysts, is facilitated by a preliminary evacuation of the contents of the cyst provided the presence of parasites has been ruled out. A ten year follow-up in the author's case shows no apparent morbidity after splenectomy. One case of normal gestation in a splenectomized woman is added to those previously collected.

Nutritional Edema—Jones and Eaton present data on thirty-four patients who developed a critically low amount of serum protein following routine surgical procedures. Some degree of edema was present in most of them. They suggest that usually such low values for serum protein and the consequent edema are the result of undernutrition which may take place both before and after operation. The reduction in the intake of protein is probably the most important element in their pathogenesis. Additional factors in the production of these complications may be the administration of excessive amounts of fluid and salt after operation, especially by the intravenous route, profuse surgical drainage, the general effects of sepsis, loss of serum protein by massive hemorrhage, and a retention of base due to temporary disturbance of renal function. The authors discuss the possibility of the occurrence of edema even in the presence of apparently normal values for serum protein and that of a nutritional edema of the intestinal wall as a cause of a poorly functioning gastro-enterostomy. They suggest the advisability of performing a preliminary jejunostomy for feeding purposes in patients who are obviously undernourished and who require major gastric surgical procedures. If intestinal edema develops after a surgical procedure, it may be combated by attempting to raise the serum protein by limiting the intake of water and salt or alkali, or by producing a diuresis. When it is impossible to feed large amounts of protein repeated transfusions are of some immediate benefit. Transfusion of plasma alone would be the most advantageous if such a procedure could be carried out. The most efficient methods of

producing a diuresis consist in the administration of the mercurial diuretics intravenously, or by the intravenous administration of concentrated solutions of dextrose. Digitalis is of no value.

Bone and Calculi in Kidney—Huggins describes a type of bone formation located in the medulla of the human kidney and associated with calculi in the collecting tubules. In the previously reported cases of ossification in the human kidney, the bone was found in close association with the pelvis. The origin of the bone is of interest from a theoretical standpoint. The author made a search for areas of mucosa of the renal pelvis in close association with the bone, but found none, so that it was necessary to discard the idea that the bone arose as a result of an epithelial stimulus. The bone in each case was in immediate proximity to stone formation, and there were many locations where direct union occurred between the bone and stone. This is considered strong evidence that the bone formed in a somewhat similar way to the histologic picture of creeping substitution in which there is invasive replacement of aseptic dead bone by new living bone. The point of greatest theoretical interest is that in the present cases the process is a creeping substitution of stone by bone. This is considered good evidence that accumulation of calcium salts that are of difficult solubility can provide a stimulus for bone formation in a certain connective tissue. As Phenister and Hellstrom emphasize, it is probable that bone formation in kidneys containing calculi occurs more frequently than the literature indicates.

Diabetes Mellitus and Pernicious Anemia—The three cases of diabetes concomitant with pernicious anemia presented by Watson bring the total up to seventy-nine. Correlating the tendency to low or absent gastric hydrochloric acid in diabetes with the fact that achlorhydria is of prime importance in pernicious anemia affords some explanation why there may be a tendency for the latter disease to develop as a complication of the former. The actual role of the so-called duodenal hormone in carbohydrate metabolism has not been definitely established but assuming that it does exist and that its function is to stimulate the secretion of insulin by the islet cells of the pancreas as postulated by Loughton and Macallum, lowered carbohydrate tolerance might be caused either by excessive production of this hormone or by its deficiency. The latter complication is a possible accompaniment of the achylia gastrica that occurs in pernicious anemia. The rapid emptying rate of the stomach in pernicious anemia may allow for excessive

stimulation of the hormone leading to fatigue and ultimate functional breakdown of the pancreatic islets, in accordance with the theory of diabetes advanced by Macallum. These factors, acting together with the rapid absorption of sugar from the intestinal tract, supply a sequence of circumstances that well might lead to a state of abnormal carbohydrate metabolism. The facts adduced from the recent literature relative to the clinical association of diabetes and pernicious anemia suggest that gastric analysis should be included in the routine investigation of patients with diabetes mellitus and that careful blood examinations should be made from time to time for evidences of the advent of pernicious anemia, especially in patients with low or absent gastric hydrochloric acid. Likewise, patients with pernicious anemia should be examined for signs of disturbed carbohydrate metabolism.

Infestation with *Strongyloides Stercoralis*—Cadham reports a case of severe *Strongyloides stercoralis* infestation in a patient who responded favorably to medication with thymol, evidently the parasite was eradicated, yet several observers claim that frequently no relief, or at best but a temporary beneficial result, is obtained by the use of this drug. DeLangen suggested the use of gentian violet, since the adult parasitic worm is susceptible to its toxic effect. The dye is given in coated tablets by mouth over a period of several days. Faust reports the beneficial results obtained in 200 patients suffering from strongyloidosis, to whom the dye had been administered. He speaks highly of this method of treatment. In the case reported by the author, the patient presented the symptoms characteristic of a severe *Strongyloides stercoralis* infestation—intermittent attacks of diarrhea associated with neurasthenia, epigastric distress and recurring urticaria together with progressive anemia, some edema and extreme emaciation. The presence of the parasite was finally disclosed, but exhaustive examination failed to reveal any concomitant infection.

Vaccine in Bacillary Dysentery—Johns and Chalk have successfully controlled bacillary dysentery, endemic in one ward of a mental hospital, by the oral administration of dysentery vaccine. The preparation and administration of the vaccine is simple, and no reactions were encountered. The vaccine was prepared with the Flexner strains of *Bacillus dysenteriae* isolated from the patients in the ward. Large flasks of nutrient broth were heavily seeded with a growth of twenty-four hours from agar slants and were incubated for four days at 37°C. The organisms were then killed by heat and the suspension of dead organisms in broth was used directly, no preservative being added. There was no preliminary preparation of the patients, and the vaccine was given in place of the evening meal. Five doses were given in six days. The dose on the first day was 10 cc, on the next three days 20 cc each day, on the fifth day no vaccine was given, while on the sixth day the final dose was 40 cc. The immunity produced is not permanent but is effective for at least one year. The administration of dysentery vaccine by mouth is followed by the appearance of demonstrable agglutinins in the blood serum. It appears probable that the method is worthy of wider application and could be used successfully in other gastro intestinal infections.

Multiple Sclerosis and Paresthesias—Saucier fully endorses the opinion of Guillain as to the frequency of the rapid onset of the disease as compared with the slowly developing malady described by Charcot. The unusual onsets are obviously not to be found in the chronic form of the disease. The acute aspects of disseminated sclerosis are apt to puzzle the observer. The symptoms are capricious and easily misinterpreted and one will frequently be misled if one does not look at once for disseminated lesions and for fine and unobtrusive indications of the disease such as minute pyramidal, vestibular and cerebellar dysfunction. Even if apparently trivial and apparently not fitting into the ensemble the fact of the dissemination of infected foci is tremendously important. The author reports four cases of multiple sclerosis with unusual onsets which embodied the following symptoms: a slight nystagmus; discrete pyramidal or cerebellar signs; polymorphous and changeable localizations; and a capricious course of evolution. Other ways of reaching diagnostic evidence may be available but the clinical picture is so typical that no experienced clinician should be misled. The

real difficulty arises when such symptoms are absent or so discrete as to baffle the observer. In such instances, complete anamnesis should bring out evidence of early manifestations, such as the paresthesias. Even if they did occur several years before, they should be given their full value. They ought to be considered as the most constant and earliest of all the symptoms of multiple sclerosis.

 Does Quinine as Used in Induction of Labor Injure the Ear of the Fetus? H. M. Taylor, Jacksonville—p. 20

Treatment of Hemophilia with Ovarian Extract—Spoto reports two cases of hemophilia treated with ovarian extract. He is of the opinion that the same hormone may prove of definite value in the treatment of hemorrhagic disease of the new-born. Ovarian therapy seems to be specific in its action and will afford relief from symptoms as long as sufficient quantities are administered to make up for the sex hormone deficiency in the hemophilic person. One of his patients was given, subcutaneously, 1 cc of ovarian extract daily for a period of twelve days. Twenty-four hours after beginning treatment, the bleeding had decreased considerably and by the following day had ceased entirely. A blood analysis showed hemoglobin, 47 per cent, erythrocytes, 3,300,000, the coagulation time was seven minutes, and the prothrombin time was sixteen minutes. At the suggestion of Birch, the patient was put on ovarian substance by mouth, taking 15 grains (1 Gm.) in divided doses daily.

Plastic Operation for Urethral Stricture—Stern devised a means for the radical cure of stricture at the bulb by means of a plastic operation. The patient is placed in a lithotomy position. An inverted V incision is made, the apex of which corresponds to a point about an inch above the position of the beak of the staff in the urethra, its lower arms extending nearly to the ischial tuberosities. The skin flap is dissected carefully so as not to injure the thin muscle layers overlying the corpus spongiosum. The bulbocavernosus muscles are separated from above downward in a median line carefully escaping the corpus spongiosum. A hemostat is so placed as to grasp the insertion of the corpus spongiosum and the transversus perinei muscles on either side and an incision is made mesial to the hemostats, leaving a muscle stump attached to the corpus spongiosum. The elevation of the corpus spongiosum from the triangular ligament and from the urethra itself is easily accomplished with the aid of scissors. This procedure is carried as far as may be necessary, exposing that portion of the urethra in which the staff is arrested and for a short distance above it. The strictured urethra is now exposed and the tip of the staff when pressed down causes the urethra below the point of engagement to pucker in advance of it. Two Allis clamps grasp the urethra, one above the strictured area and the other well below

it. A linear incision in the midline is made between these two points, opening the strictured area. Allis clamps are attached to the free edges exposing the interior of the urethra, bringing into view the beak of the staff and the filiform. These two lateral flaps are removed with scissors, leaving an ovoid opening in the urethra. A rubber catheter, size 22 F., is inserted into the bladder and the filiform is removed. The open end of the catheter is slipped over the beak of the staff and with drawn through the urethra. The urethra is repaired and all structures are replaced in their normal positions. The corpus spongiosum is attached to the superficial layer of triangular ligament by two sutures of fine catgut. A single suture is so placed as to bring the two bulbocavernosus muscles and transversus perinei muscles in apposition to the muscle stump remaining on the corpus spongiosum. This suture includes the levator ani, which frequently drops away when the transversus perinei muscles are severed. When this suture is tied the strictures are restored to their original positions and the union of the bulbocavernosus muscles completes the muscular repair. The skin flap is replaced. The corpus spongiosum is restored to its position over the urethra and fixed by its extremity to the triangular ligament. Close apposition may be expected in a week or ten days while the catheter remains in the urethra. After the expiration of this time no urinary leakage is to be expected and the patient is permitted to void normally.

 *Two Useful Staining Methods for Human Hypophysis F. B. Kindell, Baltimore—p. 56

Extirpation of Right Cerebral Hemisphere in Man—Dandy studied the physiologic results following extirpation of the entire right cerebral hemisphere, i. e., external to the basal ganglia, in three cases. One of these patients lived two years and two months, one six months and the other one died ten days after the operation from meningitis. The surviving patients were always perfectly oriented as to time, place and person. Their memory for immediate and remote events was unimpaired. They could read, write and compute without error. The author does not say that the mentality of the patients was normal, but rather that abnormalities have not been disclosed. The best proof of a normal mind was denied these unfortunates because of hemiplegia that is to carry on in the competitive world. Both patients were always coherent, at no time were there abnormal fears, delusions, hallucinations, confabulations, expansive ideas or obsessions. Neither was there undue melancholy or euphoria. One of the most interesting observations was the preservation of function in the domain of the cranial nerves, i. e., evidence of autonomy of these nerves. None of the extraocular movements were altered or impaired in the slightest nor was there nystagmus at any time in either patient. Function in the trigeminal and facial nerves was preserved. Some movement in the leg of both patients was preserved. There were no contractures such as one sees in the many clinical examples of hemiplegia.

Staining Methods for Hypophysis—Kindell describes two methods that have been found to stain differentially in the same section the eosinophil and the basophil cells of the human hypophysis removed at necropsy. The fixation permits the preparation of sections through the whole hypophysis rather than from bits of tissue. The first using fuchsin-methyl blue is a modification of one of Bailey's methods with the substitution of aqueous methyl blue for acid violet. The methyl blue was

found to have less decolorizing action on the fuchsin and with necropsy material a greater affinity for the basophil granules. The second method, the eosin-methyl blue stain, has been referred to by Romeis and by Collin and Mann. The differentiation of the first method has been found preferable.

Fractures of Vertebrae—Mitchell is of the opinion that isolated fractures of the articular processes of the lumbar vertebrae occur as a result of indirect violence. A severe force causing the spine to be flexed both forward and laterally and at the same time rotated produces impingement of the subjacent articular processes. The capsules which are attached to the margins of the articular processes are placed under considerable tension. It is the force is sufficient the combined action of impingement and capsular pull will produce a fracture of the tip of one or both of the subjacent processes. The author reports eight such fractures in five patients; three of whom

exhibited double lesions. An analysis of the lesions reveals that five of the fractures involved inferior processes. The processes of only the second, third and fourth lumbar vertebrae were involved, possibly owing to limited mobility in this region as compared with the dorsolumbar and lumbosacral joints. The location of the line of fracture varied from 0.3 to 1.2 cm. in distance from the tip of the process. Conservative treatment gave satisfactory results with three patients who were observed some months following injury. Treatment consisted of a short period of recumbency, followed by physical therapy and the application of a support, such as a canvas belt or a Goldthwait back brace. Two patients did not respond to conservative treatment, and on these a spinal fusion was performed. At operation the involved processes were exposed, the fractured tips and the cartilage of the facets were removed, and a tibial graft was placed between the split spinous processes. Immediate relief of symptoms was noted in both patients following operation, and one patient has had no recurrence of symptoms in ten months. The other patient has remained symptom free since his operation three months ago.

Spinal Fusion—During the last nine years, Henry and Geist have used the following technic for fusion of the spine. Shoulder rests are used to raise the chest slightly from the operating table. A midline incision, 12 inches in length, is made, centering over the area to be fused. The cut edges of the skin are iodized, before being walled off with towels. The fascia and the supraspinal ligaments are incised longitudinally, together with a portion of the interspinous ligaments, so as to expose freely the tips of the spinous processes. At least two segments above and below the affected area are fused. With a broad raspator, the periosteum and muscles are detached from the spinous processes and laminae as far laterally as the articulations. Hemorrhage is controlled by packing. The entire area to be fused is exposed by laterally retracting the spinal muscles. The laminae are cleaned of all soft parts from the bases of the spinous processes out to the articulations. By means of a hand chisel, the spines being used for leverage, small thin shavings of bone are removed from the laminae until their exposed surfaces are entirely raw. The spinous processes with their intact interspinous ligaments are clipped off at their bases with bone cutting forceps. One spinous process at each end of the field is cut obliquely to avoid disfiguring bumps. From the subcutaneous surface of the tibia, exposed by a second operating team, multiple chip grafts are removed with a chisel. During their collection, the chips are placed in a cup of physiologic solution of sodium chloride. The cup of chips is kept warm in a pan of sterile water. A large handful of these chips is needed. The chip grafts are distributed evenly over the spinal bed and pressed into contact with the raw laminae and one another by the use of the broad blade of a raspator. The periosteum the muscles, the remaining supraspinal ligament and the dorsal fascia are sutured over the grafts with interrupted chromic catgut. The subcutaneous fat is closed with continuous plain catgut and the skin with dermal catgut. The incision is iodized and antiseptic surgical varnish is painted around the wound decreasing the danger of wound contamination by perspiration. The stitches are removed after twelve days and a close fitting plaster-of-paris cast is applied on the Goldthwait irons. After ten weeks the patient is fitted with a brace of the Osgood type, having axillary crutches, which is usually worn for about three months.

Os Subtibiale—Lapidus reports two cases of bilateral extremely rare inconstant bone, the os subtibiale, one in an adult the other in a child. An accessory center of ossification over the tip of the medial malleolus is occasionally observed in children appearing around the age of 6 and fusing at about the age of 13. This accessory center and the os subtibiale seem to be two different entities though they may have some relation to each other. The first group may be classified as an inconstant center of ossification or possibly an epiphysis of the medial malleolus somewhat similar to the one observed over the styloid of the fifth metatarsal. The cases observed in children seem to fall in this group. The second group of cases, all observed in adults, are best fitted into the classification of an inconstant bone—os subtibiale. Accessory scaphoid or trigonum or accessory center of ossification of the distal radius may be considered homologous with os subtibiale.

Complement Fixation in Tuberculosis—According to the studies of Rice and her associates, an examination of serums from 100 patients suffering from active pulmonary tuberculosis by routine quantitative methods of complement fixation has shown no consistent correlation between the clinical history and the antibody titer of the serum. The authors observed that tuberculosis serums do not all react equally well with carefully tested antigens prepared from S and R cultures of human tubercle bacilli. These two antigens are about equally efficient in detecting the complement-fixing antibodies in serums from cases of the chronic type, but the S antigen fixes specifically, in the presence of serum from the majority of acute cases twice as much or more complement than is fixed by the R antigen. Serum from cases of the intermediate type usually fall between these extremes. From the small number of cases studied, it would appear that the relative reactivity of serums with S and R antigens is more closely correlated with the activity of the tuberculous processes than is the actual concentration of complement-fixing substances.

Excretion Urography with Neoskiodan—Moore employed neoskiodan in fifty instances of excretion urography. He states that the substance does not provoke pain on injection. It is productive of shadows of the urinary tract of excellent density and detail. Its intravenous administration has been almost devoid of systemic symptoms. The volume of solution injected in the adult human being is small (20 cc.) and the quantity of substance only 7 Gm. The aqueous solution is stable. His experi-

ence thus far leads him to the impression that it more nearly approaches the ideal than any agent so far developed for excretion urography.

Melanotic Sarcoma of the Suprarenals—McComb and Smith report the case of a man, aged 65, who was operated on and a melanotic sarcoma removed from the bladder. Thirteen months later the patient died of circulatory failure. At necropsy a primary bilateral malignant condition of the suprarenals was discovered with multiple secondary melanotic growths in subcutaneous tissue. The pheochromocyte is considered a possible type cell of the growth.

Gas Gangrene and Gonorrheal Epididymitis—Balch presents a case of acute gonorrheal epididymitis that terminated fatally with an extensive gas gangrene of practically the entire trunk of the body. Although *Bacillus welchii* was never found either by smear or by culture, the small encapsulated gas forming bacillus yielded by cultures proved to be exceedingly fulminant. The entire urethra was found to be intact. The infection was a directly continuous process along the cord from the epididymis to the tissues of the abdominal wall. Another unusual feature of this case was the fact that the epididymis ruptured spontaneously and drained through the scrotum which is not the usual sequence of a gonorrheal epididymitis. In explanation of this infection, the author states that it seems probable that the sinus became contaminated in some manner with the gas bacillus, which rapidly terminated the patient's life.

Effect of Phenol and Merthiolate on Appendiceal Stumps—MacLean shows that tincture of merthiolate used on the appendiceal stump is far more effective than the commonly used phenol and alcohol technique. The appendices removed in twenty-five consecutive cases were doubly clamped with sterile hemostats. The appendix was then cut through between the forceps with a sterile knife. The bulk of the appendix was cut loose from the one hemostat leaving four available stumps, of which three were used in each case. One of these stumps was treated with phenol followed by alcohol, another was treated with tincture of merthiolate (1:2000) the third was left untreated. Cultures of the three stumps were then taken by smearing on fresh nutrient agar plates. In each case the solutions were applied with sterile applicators having a small twisted wad of cotton on the end. Tincture of merthiolate sterilized twenty-two of the twenty-five appendiceal stumps. Tincture of merthiolate is not injurious to the peritoneum.

Treatment of Morphism with Insulin—For the past year Howard has been relieving symptoms produced by the sudden withdrawal of morphine by substituting insulin for morphine. He found that there was an increase in the blood sugar of about 25 mg when withdrawal symptoms were first noticed by the patient. This varied with each patient, as the onset of such symptoms would be influenced by the individual psychologic factor. As a rule his patients would not allow withdrawal symptoms to persist any length of time, so in order to avoid desertion of the patient blood sugar observations prior to the substitution of insulin were followed for only a short while. The author believes that there is a decrease in the basal metabolic rate of about 10 per cent during the onset of withdrawal symptoms. Physical examination for the most part disclosed nothing except a drop in blood pressure concomitant with the withdrawal of morphine from an addict. Patients who have been taking more than 3 grams (92 Gm) a day over a period of six months or longer should have the dose gradually reduced by half before insulin is substituted for the morphine. This can generally be accomplished with little discomfort to the patient. The dosage of insulin varies with the requirements of each patient.

Parenchymatous Cortical Cerebellar Atrophy—Parker and Kernohan outline the characteristics of parenchymatous cortical cerebellar atrophy. The histologic observations at necropsy are readily recognized. Clinically, the disease represents a slowly progressive cerebellar syndrome, beginning after middle age in both men and women. The diagnosis need not be difficult except when separating the clinical syndrome from other types of cerebellar degeneration. The failure to obtain a history of hereditary characteristics and the relative purity of the cerebellar syndrome are of assistance in the latter respect. Arteriosclerosis with infarction of the cerebellum produces a clinical course that is abrupt and intermittent and lacking the smooth progressive course of the disease outlined. The disease usually begins before senile changes are manifest, and the preservation of the intellectual faculties distinguishes it from a general senile breakdown of the nervous system. The disease is rare only twelve cases, including the one the authors report have been recorded in which necropsy has verified the identity of the process. Interest in the condition is created by the observation of a clear cut clinical syndrome and a specific destruction of cells in the cerebellum.

- *Radium Burns J M Thomas—p 55

Radium Burns—Thomas gives the following points for the prevention and treatment of radium burns. 1 Radium treatment should not be given to patients suffering from cachexia, anemia, a white cell count under 5,000 per cubic millimeter, diabetes, nephritis, extreme obesity, advanced myocarditis, active pulmonary tuberculosis, marked arteriosclerosis or any general debilitating disease, general sepsis, local inflammation or infection. 2 There must be no ulceration of the skin immediately prior to treatment. 3 The skin must be cleansed and lightly powdered before the plaque is applied and this must be repeated on alternate days to insure the absence of perspiration or fetid discharge irritating the skin. 4 The plaque should fit the area to which it is applied firmly and without friction. 5 It should be removed at once on the appearance of edema of the skin (clinical edema dose). 6 The part should be subsequently well powdered or calamine lotion applied. No soap should be used for two months. 7 Following radiotherapy, there should be no friction or irritating apparel. 8 The plaque should be removed as soon as the burn appears and the radium treatment discontinued. 9 The area should be cleansed thoroughly without soap and a dressing of eucalyptus and petro-

latum (5 per cent) applied. This should be replaced by sterile liquid petrolatum at a later stage when healing is evident. 10 The use of powders should be avoided at this stage. 11 Rest should be secured. 12 When healing is intractable, it may be aided by an erythema dose of ultraviolet radiation. This method of treatment and the oily antiseptic dressing, which does not hurt the patient when it is removed, keeps the scar supple, promotes healing, lessens discharge and promotes epithelialization without undue granulation.

Suprarenals and Anesthetic Hyperglycemia.—Banerji and Reid investigated the part played by the suprarenals in increasing the blood sugar during a thirty minute surgical anesthesia by the operative indirect and comparative methods. Rabbits and, for some observations, dogs were used. A series of thirty rabbits of about 1.5 Kg. was prepared by two stage aseptic operations under open etherization which aimed at decreasing or immobilizing the available epinephrine by double suprarenalectomy (group 1), unilateral suprarenalectomy with contralateral medullisuprarenalectomy (group 2), and double medullisuprarenalectomy (group 3). During surgical etherization the increase in blood sugar was invariably greatest in the intact rabbit, slightly less after the first and least after the second operation. The glycemic response of the group 1 rabbits with signs of suprarenal insufficiency was noticeably small and doubly so two or three days before death. The glycemic response of the group 1 rabbits that survived for long periods in good health was slightly less than for groups 2 and 3. The fasting blood sugar level was low (from 40 to 60 mg. per hundred cubic centimeters) in those rabbits with signs of suprarenal insufficiency. In groups 2 and 3 the average fasting blood sugar level was from 85 to 90, as compared with 105 to 115 for the intact animals. In the group 1 rabbits dying of suprarenal insufficiency the loss of weight was progressive and averaged 20 per cent at death. In the other groups the weight decreased slightly after the operations but remained more or less steady thereafter. In the indirect method, amytal partly inhibited the hyperglycemia occurring normally in ether or chloroform anesthesia in rabbits and dogs. Amytal checked the normal glycemic response to morphine more than that to ether or chloroform. Amytal did not prevent epinephrine hyperglycemia of the normal order. The alkali reserve was decreased during ether or chloroform anesthesia but not with amytal. In the comparative method the anesthetic glycemic response was greater in the group of rabbits that had shown previously a large increase in blood sugar in response to epinephrine than in the group less sensitive to it. The authors conclude that the suprarenals are concerned partly in increasing the blood sugar during a thirty minute surgical anesthesia with ether or chloroform.

Ammonium Chloride and Barometric Pressures.—Douglas and his associates observed the influence of the preliminary ingestion of a moderate dose of ammonium chloride in a subject exposed to a barometric pressure of 347 mm. in a steel chamber. After treatment with ammonium chloride the subject showed a lower alveolar carbon dioxide pressure and a higher oxygen pressure, a lessened degree of cyanosis, a slower

pulse rate and a greater ability to perform muscular work than in experiments in which no ammonium chloride had been taken. The authors discuss the bearing of these results on the question of acclimatization to high altitudes.

Observations on Iichen Urticatus. H. Gordon.—p. 126

Endocrine System and Blood Disorders.—Hubble reviews the clinical and experimental evidence relating to the effect of the thyroid, the cortex of the suprarenals, and the anterior lobe of the pituitary on hematopoiesis. It is shown that the thyroid hormone stimulates the production of red cells and lymphocytes and depresses the output of granulocytes, the suprarenal cortical hormones stimulate the production of granulocytes and possibly also of red cells, while the basophil cells of the anterior lobe of the pituitary stimulate all types of circulating cells giving rise to a clinical picture of polycythemia. It is possible that the anterior pituitary produces this leukopoietic result indirectly through the thyroid and the suprarenal cortex. It is suggested that in hyperplasias and hypoplasias of the circulating blood cells a primary disorder of the endocrine system is the dominant etiologic factor. The clinical parallelism between exophthalmic goiter and chronic lymphatic leukemia is displayed with particular reference to Friedgood's work on the response of the basal metabolic rate, the pulse rate and the cell count in lymphatic leukemia to treatment with compound solution of iodine. It is concluded that the cause of lymphatic leukemia is a primary dysfunction of the thyroid. It is suggested that an excess of a suprarenal cortical hormone is responsible for myelogenous leukemia, and it is pointed out that polycythemia is a cardinal sign of hyperplastic conditions of the anterior lobe of the pituitary. Two hyperplasias of the bone marrow are considered, agranulocytic angina and aplastic anemia, and some further evidence is reviewed which also suggests for them an endocrine etiology.

Insulin and Diabetes Mellitus.—Leyton believes that insulin will cure diabetes mellitus if given in adequate amounts. An adequate dose of insulin must rest the pancreas. The dose of insulin will depend on the diet prescribed. In the majority of adults the acceptable diet is found to contain more than 150 Gm. of carbohydrate, and the amount of protein and fat differs greatly in different people. The lower the sugar content of the blood can be kept the greater the chance of the patient making a recovery. The idiosyncrasy of the patient has to be taken into consideration. The ideal is to arrange food and doses of insulin to keep the sugar content of the blood between 0.08 and 0.15 per cent throughout the twenty-four hours. In severe cases on a diet fairly rich in carbohydrate this may necessitate three or even four injections of insulin in the twenty-four hours for a time, it is a great exception for more than two to be needed for longer than six months. The interval between the injection of insulin and the meal must be determined by a trial in each case. After a meal rich in carbohydrates the sugar content of the blood will tend to rise and, if the dose of insulin is sufficient to prevent this exceeding 0.15 per cent, there is considerable probability that between three and four hours after the injection the sugar in the blood will fall low enough to cause symptoms. This is prevented by the patient taking a small amount of carbohydrate in a form that is easily assimilated about two and a half hours after the injection of insulin. The quantity must be determined by trial. Insulin may be hampered in its action by the patient taking substances that stimulate the cells of the islands of Langerhans to secrete, the most important of these is alcohol. Toxins elaborated by viruses or micro organisms may retard recovery. A patient who has had an acute attack of diabetes mellitus may have further attacks.

Quantitative Effect of X Rays on Mitosis in Mouse Carcinoma (M 63) W H Love —p 70

Functional Dyspepsias—Diethelm considers functional and nervous disorders of the stomach in three main groups (1) true functional cases, including the dynamic disorders characterized solely by disturbed motility or aberrations in secretion, either in quantity or in quality, (2) functional disturbances that are merely reflex manifestations, and (3) the gastric neuroses, the two main groups of which are the transference neuroses or psychoneuroses and the physioneuroses, also known as actual or somatic neuroses. Etiologic factors in successful therapy include mental and psychic factors, alcoholic excesses and sexual abuses. Other causes are dietary habits, excessive or injudiciously chosen foods, mental excitement during meals, dental factors and the excessive use of tobacco. Finally, trauma has to be considered if there is a possible traumatic neurosis. Of all gastric disorders, at least from 60 to 70 per cent are nonorganic. They are most common probably in the third or fourth decade. The chief symptoms are pain or distress, nausea, vomiting, belching and flatulence, heartburn, epigastric fullness and substernal pressure, disturbances of appetite and hunger, constitutional and nervous symptoms in the shape of headache, cardiac palpitation, insomnia, lassitude, mental depression or irritability, an inability to concentrate and certain vasomotor disturbances, such as sweating, faintness and dizziness. As a general rule actual pain does not occur and its absence helps to differentiate functional from organic disease. Vomiting, particularly if irregular, is, on the whole, more characteristic of functional disturbances of the stomach, unless there are signs of organic stenosis or pylorospasm. Headache is not a symptom of uncomplicated organic gastric disease. Habitus enteroproticus is common. Gastric analysis does not assist much in the actual diagnosis of a functional or nervous dyspepsia, excepting when there are bizarre curves not suggestive of any organic lesion. Fractional test meal curves, however, are most helpful in the matter of therapy.

Prenarcosis by Morphine and Paraldehyde—According to Garrett and Gutteridge, morphine, paraldehyde and scopolamine in suitable dosage, are of value as basal narcotics for operations under local anesthesia. Morphine and paraldehyde, as a preliminary to the induction of general anesthesia are useful in relatively short operations and tide the patient over the painful recovery period. These drugs are unsuitable for cases presenting much pulmonary fibrosis or coronary sclerosis. An enema is given the night before the operation. This clears the rectum, provides space for the injection, diminishes the possibility of rejection of the paraldehyde solution, and assists absorption of the drug. An hour before the operation a hypodermic injection of 0.015 Gm of morphine and 0.65 mg of scopolamine is given. Fifteen minutes later, 0.25 cc of paraldehyde per kilogram of body weight is dissolved in ten times its volume of physiologic solution of sodium chloride and is injected slowly into the rectum. Inevitably before this injection has been completed the patient falls into a heavy sleep, often with slightly stertorous breathing and during the subsequent administration of the local anesthesia by injection as for instance, into the branches of the trigeminal nerve makes muttering noises and vague restless movements easily controlled. If the narcosis is not complete mild complaints are made of a vague kind but these cease rapidly on complete block of the painful stimuli and the patient again drifts off into a sleep. During the operative procedure it is unusual for any complaint to be made and these occur only at the time of eroding or chiseling on bone. On completion of the operation the patient is still sleeping and remains so for a variable period of from one to four hours. Among the authors' 143 cases there has been so far one death associated with the method.

This was a case of gross tuberculous involvement of the larynx with obstruction to breathing in which a tracheotomy was performed. The patient died of respiratory failure having an associated tuberculous and bronchiectatic involvement of the lung and asthma. The authors give a description of the effects and results of morphine, scopolamine and paraldehyde pre-narcosis on a few patients who deviated from the usual.

Improved Zondek-Aschheim Pregnancy Test—Nojima and Katahira state that two or three injections of 5 cc of pregnancy urine per kilogram of body weight into the auricular vein of the rabbit will give a positive reaction in twenty-four hours. At times it was possible to detect a positive reaction in from twelve to fifteen hours after three injections and also a weak positive reaction was obtained in twenty-four hours after a single injection. Fresh hemorrhages in the ovarian follicles are considered to be a positive reaction. In the authors' twenty-three cases the hemorrhagic reaction was seen outside the follicles twenty-four hours later. This reaction appeared to be more intense in the mature animals. The reaction was especially accurate in its result in the early diagnosis of pregnancy and according to their experiment if pregnancy existed a positive reaction was obtained before the appearance of the next anticipated menstruation. When the urine of a pregnant woman was injected subcutaneously a strong positive reaction was shown forty-eight hours later by three injections of 4 cc of the urine. In the case of boiled urine the reaction was negative.

 *Early Bilateralization in Artificial Pneumothorax C Garin Treppoz and Bouquin—p 1422

Early Bilateralization in Artificial Pneumothorax—Garin and his associates state that bilateralization occurring immediately or a few months after artificial pneumothorax and appearing to be part of the same attack is most frequently observed in the forms of tuberculosis characterized by more or less diffuse nodular lesions. The nodules, which have an average diameter of 1 mm, can be seen only on roentgenograms, they may appear isolated, disseminated over the whole lung, or in groups. Other lesions may also appear on the films, but the nodular lesions predominate. In nine out of ten early bilateralizations seen by the authors in 130 cases of artificial pneumothorax the primary lesion was of the nodular type. In all cases the extension assumed the same form as the primary lesion. Occasionally the early bilateralization is revealed by cough or unexplained fever but usually its clinical manifestations appear as a part of the as yet unimproved original pulmonary process, and the new lesion is diagnosed only by roentgenography. The authors do not think that artificial pneumothorax in strictly unilateral cases favors bilateralization, it is merely ineffective in preventing it. However, in cases not strictly unilateral, lesions of the bronchopneumonic type on the opposite side are given a sudden impetus by the pneumothorax. In nodular forms, therefore the unilaterality must be determined with the greatest care and granular lesions of the opposite hilus should be regarded with suspicion. Treatment of early bilateralization should consist at first of rest, maintenance of the pneumothorax under weak pressure and gold therapy (three injections of 0.15 Gm a week, up to 4 or 5 Gm). Only later, if the lesions become fixed or if a localized cavity develops, may bilateral pneumothorax be resorted to, as an exceptional therapeutic measure.

Policlinico, Rome

40 569 648 (Sept 1) 1933 Medical Section

- *Clinical and Roentgenologic Notes on Treatment of Gastroduodenal Ulcer with Sodium Benzoate A Pozzi and L Sforza—p 569
 Value of Encephalography in Diagnosis of Cerebral Tumor T Luchermi—p 596
 Constitutional Sporadic Hemolytic Icterus with Dyscrimic Pluriglandular Syndrome Splenectomy E Jancarelli—p 632

Treatment of Gastroduodenal Ulcer with Sodium Benzoate—Pozzi and Sforza treated twenty patients suffering from gastric and duodenal ulcer with daily intravenous injections of a solution of 0.5 Gm of sodium benzoate in 2 cc of water. During treatment the patients were deprived of meat, sugar, alcohol and tobacco. The injections were well tolerated by all patients. Gastric pain was often manifested after from four to five injections but gradually diminished. Epigastric pain is more easily and more rapidly influenced by the injections of sodium benzoate since it may definitely disappear after from twenty to twenty-five injections. On the other hand patients at that period of treatment still complain of acid eructations and heartburn on fasting as well as after eating. These patients showed a gain of from 2 to 3 Kg in weight in two months. There never was complete evidence of improvement in a patient until from forty to fifty injections had been given. Long continued cases required at least from sixty to seventy injections, others were prolonged to more than 100 injections. While this treatment proved only slightly efficacious in cases of ulcer complicated with pyloric stenosis or with other abdominal lesions (chronic appendicitis) the authors obtained their best results in cases of simple gastric and duodenal ulcer especially when the treatment continued beyond fifty injections. In gastric ulcer the clinical improvement seemed to be more rapid than in duodenal ulcer. The authors found that clinical improvement is not always accompanied by roentgenologic modifications in the majority of cases showing this improvement the niche was evident in the roentgenogram. In instances of prolonged treatment evidence of the niche may be difficult to find because of the edematous and spastic condition of the muscular layer of the mucosa. The niche may

appear after many doubtful roentgenograms, thus indicating that a negative roentgenogram does not justify the assumption of a cure. The author, therefore, maintains that great care must be exercised in the interpretation of roentgenograms.

- *Treatment of Cerebral Arteriosclerosis H Roxo—p 581
 *Folliculin Treatment in Prematurely Born Infants A Rocha—p 583
 Primary Nasal Diphtheria Thirty Cases D Moreira—p 584
 Acute Meningitis Case A J de Siqueira—p 586
 Surgical Treatment of Gastric Neoplasms N Burlamaqui Benchimol—p 588

Treatment of Cerebral Arteriosclerosis—Roxo classifies the patients into two groups: those who never have had epileptiform attacks and those who have had them. Sodium iodide is indicated in patients of the first group since it modifies the viscosity of the blood, lowers the arterial pressure and does not cause irritation of the cardiac muscle. Some authors prefer injectable preparations of sodium phosphate. The intravenous injection of a complex carbimide compound of trisulphonic acid (germannin) produces satisfactory results especially if followed by the administration of digitalis and of sodium citrate. Various other treatments, such as electricity (high frequency currents), hydrotherapy (in the form of carbogaseous baths) and hypotensive drugs are also indicated. Fly blisters, placed behind the ears, relieve the buzzing in the ears. In patients of the second group it is necessary to determine if there is cerebral hemorrhage or cerebral ischemia caused by embolus or thrombosis. The old practice of bleeding patients having cerebral hemorrhage complicating cerebral arteriosclerosis should be stopped. The application of an ice pack to the head and hot water bags to the legs, the injection of hydrastinine or a liquid preparation of ergotamine tartrate and the administration of enemias with sodium sulphate of castor oil as well as of other drugs possessing the property of lowering the blood pressure, are indicated. Lumbar puncture is of great importance not only because it diminishes the cerebral congestion but also because of its diagnostic value. If there is cerebral ischemia the cerebral circulation should be stimulated by injections of caffeine or of camphor in oil. Acetylcholine also gives satisfactory results. Intravenous injections of a 10 per cent solution of germanin given at intervals of five days should start with 0.3 cc and the dose should be increased by 1 cc at each injection until 5 cc of the solution is given at one time. An alkaline alimentation, entirely deprived of meats and fish and rich in vegetables and fruits, completes the action of germanin causing an increase of the alkali reserve to normal figures. In cases of dementia complicating cerebral arteriosclerosis the treatment indicated for this clinical form of dementia should be resorted to.

Folliculin Treatment in Prematurely Born Infants—Rocha says that the concentration of follicular hormone increases during pregnancy, to reach its maximal figures during the days previous to delivery. After delivery it begins to go down and completely disappears during the first week of the puerperium. This seems to indicate that folliculin is of importance in the development of the fetus during the last day of its intra-uterine life and that the absence of the follicular hormones would result in great disturbances in the final development of the fetus. The author believes that this is the reason for the disturbances of prematurely born infants and for the good results of folliculin treatment in those infants. Schreiber treated eighty-five prematurely born infants with folliculin. In all the infants there was an increase in weight of 0.4 per cent at the end of eleven days as compared to a loss of 2.4 per cent in those not treated. The author directs attention to the importance of the increase in weight and of the prevention of loss of weight in those infants. Schreiber observed a group of ten pairs of twins. One twin in each pair received folliculin. Those who received folliculin showed an increase of 9.5 per cent of weight during eleven days while those who were not treated showed a decrease of 1.9 per cent. In another group of twins observed under the same conditions those treated with folliculin gained 38 per cent in thirty-five days, as compared with those who did not receive the treatment. In general the dose to be injected is 100 units of folliculin per kilogram of weight of the infant.

Recurrence of Pain After Gastrojejunostomy for Ulcer—Puhl obtained twenty-four specimens of the stomach, duodenum and jejunum removed at an operation secondary to the original gastrojejunostomy performed for gastroduodenal ulcer. The author describes the histories and the anatomic observations in seven patients. On gross examination, profound changes of the mucosa of the antrum were evident in the greatly thickened mucous folds. The microscopic picture is one of hyperplastic atrophic gastritis, which is rarely observed in gastric mucosa the seat of an ulcer not operated on. The gastritis is not the result of the primary ulcers, as these were found largely healed or at best to be the seat of a mild inflammatory reaction. The duodenum was the seat of a chronic duodenitis with localized areas of atrophy. The recurrent ulcerative gastritis and duodenitis presented ulcerations involving all the layers. Puhl believes that this picture constitutes the anastomotic basis for the recurrence of pain when the interval between the original operation and the secondary operation for recurrence amounts to one year or more. He found at the anastomotic ring of some of the cases a mucosa rich in folds, edematous and covered with thick mucus. There were signs of chronic and acute inflammatory changes transformation of the fundal glands into those of a pseudopyloric type cystic dilatation of the glands and superficial erosions. He also points out the existence of a chronic jejunitis with or without ulceration. The changes were present at the stoma and close to the ulcer and for some distance away from it. In a few instances the dependence of a jejunal ulcer on a stitch abscess could be demonstrated although the author feels that the latter perhaps played only a secondary part. The author concludes that the cause of pain in gastrojejunostomies is a typical form of gastroduodenitis. This frequently occurs with formation of new ulcerations in the presence of a healed original ulcer. Stenosis of the stoma can lead to a diffuse and even an ulcerative fundus gastritis. The causative factor in the production of the jejunal ulceration is the excessive and prolonged secretion of gastric juice. These observations lend support to the empirically gained impressions as to the advisability of wider resections both in primary and in secondary operations. Resections of the antrum and pylorus alone are not sufficient. Leaving behind of pyloric mucosa is as fallacious as the preservation of the lower third of fundal mucosa. The latter was found by Breckmann as well as by the author, in gastritis the result of sham feeding experiments to be the chief source of production of hydrochloric acid because of the abundance of chief cells. Extensive resections of the type advocated by the author should be resorted to only after several courses of careful persistent internal treatment have been carried out. Roentgen diagnosis of a severe gastroduodenitis after the operation calls for an early reoperation because the deeper jejunal lesions display little tendency to healing. He emphasizes the necessity for careful medical treatment after the original operation and a diet that spares the motor and chemical functions of the stomach.

Rectal Infusion of Sodium Chloride in Postoperative Period—Genkin and Miljanskaja since 1931 have substituted in the postoperative treatment of cases of ileus a 5 per cent solution of sodium chloride for the usual physiologic solution

in the drop method of rectal infusion. Since 1932 they have adopted in some cases a modification of the method of Gosset and Soupault, consisting in slowly injecting into the rectum 100 cc of a 15 per cent solution of sodium chloride. As a result of their own clinical experience, they state that both the 5 per cent and the 15 per cent solutions of sodium chloride proved to be an effective means of combating the motor disturbances of the bowel function in the postoperative period. The infusion of the 15 per cent solution is indicated when other measures such as application of warmth to the abdomen and the rectal tube failed to accomplish the desired result. The 15 per cent sodium chloride enema can serve as a dependable differential diagnostic method in functional and mechanical intestinal obstruction. The authors feel that the safety and ease of application of the method suggest that it replace the intravenous method of introducing solutions of hypertonic salt. The infusion of the 5 per cent solution appears to be particularly useful as a postoperative measure for patients operated on for intestinal obstruction because it leads to early evacuation of the bowel and saturation of the organism with chlorides. The 15 per cent sodium chloride enema is likewise applicable in various forms of motor insufficiency of the intestine in patients with chronic inflammatory processes of the peritoneal cavity, in pseudo-ileus of renal origin and in coprostasis.

Tuberculosis of Suprarenals—Gsell and Uehlinger attempt to classify Addison's disease with the hematogenous forms of tuberculosis. They observed thirty-five cases of bilateral total tuberculosis of the suprarenals and thirty-seven cases of unilateral or bilateral incomplete tuberculosis of the suprarenals. They state that 1 The infection of the suprarenals is hematogenous because with the exception of the extremely rare placental infections that end fatally during the nursing age, the infection was always secondary, originating in a primary complex or in a postprimary tuberculous focus. 2 In all cases of tuberculous Addison's disease there were besides the bilateral, caseous fibrous suprarenal tuberculosis, also extrasuprarenal hematogenous foci of dissemination regularly in the pulmonary pleura, in the urogenital system in every third case and in the skeletal system in every fourth case. Remnants of past exudative tuberculous inflammation of serous membranes were found in every third case. In about one third of the cases the bilateral tuberculosis of the suprarenals was the only active tuberculous focus. The pulmonary tuberculous changes show the characteristic signs of hematogenous dissemination. There are as a rule only slight bilateral apical disseminations. 3 Transition to miliary tuberculosis is extremely rare. 4 The average duration of tuberculous Addison's disease is from six months to two years but this period is only the last stage of the disease, that of complete destruction of the suprarenals and of glandular insufficiency. The time required for the development has not been definitely determined as yet. The tuberculous infection of the suprarenals begins during the period of puberty or during postpuberty.

The long period of development up to the complete destruction of the organs explains the relatively late manifestation of Addison's disease in many patients between the third and the fifth decade of life. 5 With the exception of suprarenal tuberculosis acquired by way of the placenta, tuberculous Addison's disease is practically unknown during childhood. The youngest patient mentioned in the literature was 9½ years old. The disease becomes somewhat more frequent after the twelfth year has been reached, but even at this age it is still comparatively rare, and it is also rare in aged persons. 6 It is three times more frequent in men than in women. 7 The development of suprarenal tuberculosis is intermittent. Of the various types of tuberculosis of the suprarenals, the bilateral fibrous caseous form that leads to Addison's disease lasts longest. Miliary tuberculosis of the suprarenals develops within a few weeks. The large nodular suprarenal tuberculosis, which appears in the form of unilateral or bilateral conglomerate tubercles in hematogenous generalization of tuberculosis, develops in from one to five years. The development of bilateral, chronic fibrous-caseous suprarenal tuberculosis lasts many years or even decades. The period of glandular insufficiency also varies in length. It is short in generalized tuberculosis and it may be of varying duration in other forms, while it may last several months or years in classic Addison's disease. 8 Investigations as to the number of hematogenous disseminations revealed that in the majority of cases of tuberculous Addison's disease there was only a single dissemination. This proves the benign character of the tuberculous process or the defense power of the organism, and the authors think that death is due to the fact that there is no glandular tissue to replace the suprarenals rather than the result of the tuberculous suprarenal processes as such.

Method for Estimating Function of Heart—The method devised by Atzler permits the registration of the fluctuations in the form and size of the heart. The principle of the method is that the human heart is brought between the plates of a condenser and that the changes in size produced by the heart beat are registered. The capacity of the plate condenser is proportional to the dielectric constants of the medium and of the surface and inversely proportional to the distance between the plates. If a body with a different dielectric constant is brought into the dielectric, the capacity changes proportionally to the difference of the two dielectric constants of the surface and the thickness of this body. In this method it is of primary importance that the capacity changes in proportion to the volume of the body that is brought into the condenser field. Two condensers that have the approximate size of the heart are placed in the front and back so that they do not touch the person. The two plates are connected by a curved piece of metal and thus have an oscillation circuit consisting of a capacity and of a relatively smaller automatic induction. The wavelength for which the oscillation circuit is synchronized is primarily determined by the capacity of the condenser. The size of the condenser is given by the measurements of the human subject and the automatic induction is as small as possible. On the basis of Thomson's formula for the duration of oscillation, the wavelength is from 2 to 3 meters. A small transmitter that emits such a wavelength is connected with the oscillation circuit by induction. The better the circuit is synchronized with the transmitter the stronger it oscillates. However, the synchronization is independent of the volume fluctuations of the heart. If the conditions are arranged so that the work is done in the straight linear portion of the

synchronization characteristic, the synchronization is proportional to the volume fluctuations. The high frequency alternating current of the oscillation circuit is rectified by a trielectrode tube, the grid and anode of which are short circuited and is amplified by an additional tube. The amplified current is registered by a string galvanometer or by an oscillograph. The author reproduces typical dielectrograms that were obtained by this registration on normal hearts as well as abnormal hearts, and he explains the significance of the various deflections in the curve.

Hiatus Hernias and Angina Pectoris—Mosler and Haas investigated the frequency of hiatus hernias and their relation to angina pectoris. The form that in Åkerlund's classification is referred to as the third form was observed comparatively often as it was seen forty-nine times in examinations of the stomach on 1,500 subjects. In this form of hiatus hernia the esophagus has a normal length and is within the hernial sac, and the cardiac portion of the stomach has entered the thorax through the diaphragmatic opening. The authors were able to corroborate the observation that this form occurs primarily in older persons, only two of the forty-nine being less than 50 years old. According to von Bergmann (abstract in THE JOURNAL, July 2, 1932, p. 89), it is difficult to differentiate between the epiphrenal syndrome and angina pectoris. The authors, however, considered primarily patients with true angina pectoris and those with severe angina pectoris like attacks and disregarded those with disturbances of a mild nature. Of the forty-nine patients with hiatus hernia, twenty (40 per cent) had angina pectoris or disturbances resembling angina pectoris. In the patients with large and medium hiatus hernias the incidence of angina pectoris was 55 per cent, while in those with small hiatus hernias the incidence was only 31 per cent. The authors report that of thirty patients with angina pectoris ten had no hiatus hernia. They think that hiatus hernias are a frequent occurrence in aged persons.

Tolerance Tests in Diagnosis of Glaucoma—Stein points out that the functional disturbances in the intra ocular vascular apparatus play an important part in the pathogenesis of glaucoma. Whereas the normal eye has the capacity to retain an equilibrium of pressure in spite of fluctuation in the general circulation, the glaucomatous eye or the eye that is predisposed to glaucoma has lost this capacity and reacts to changes of pressure in its vascular system with an increase in its internal pressure. This changed reaction is frequently already present at a time when the clinical symptoms of glaucoma are not yet clear. Thus there is a possibility of securing an early diagnosis of glaucoma by tolerance tests. The modification of the intra-ocular vascular apparatus in order to obtain a diagnostically valuable fluctuation in pressure can be produced by various methods. The author first describes and evaluates the test in which the injection of caffeine or drinking of strong coffee is used to obtain a noticeable increase of the intra ocular pressure. Then he discusses the inhalation of amyl nitrite. This test may be modified by decreasing the number of drops to be inhaled from five to three and he shows that the diagnostic value of the test increases with this decreased dosage. Whereas the aforementioned tests are based only on the dilatation of the vessels of the head there are other tests which in addition to the increased inflow of blood also involve stasis. The latter can be produced by positional changes, particularly by lowering of the head or by constricting bandages.

—Schwartz relates the history of a woman aged 25 who since the end of December felt weak and had intermittent fever. At the beginning of January she had an abortion the pregnancy being in the eighth or tenth week. The anamnesis revealed that until two and a half months before this she had been employed on a large farm where abortion was frequent among the cattle. The patient admitted that she had the habit of drinking raw milk. The diagnosis of Alcaligenes abortus infection was based on the clinical picture and on the high

agglutination titer (1,600). The hemogram revealed leukopenia and a considerable lymphocytosis. Most symptoms were those that are usually observed in *Alcaligenes abortus* infection, but abortion except for a case reported by Frei in which the uterine secretion of a woman who had aborted four times contained *Alcaligenes abortus* has not yet been described in human subjects. The author thinks that the comparative rarity of *Alcaligenes abortus* infections in human beings and the fact that it is more frequent in men than in women and that in women it concurs only rarely with pregnancy explain the rarity of human abortions caused by *Alcaligenes abortus* infections. Another noteworthy aspect of this case was that it responded favorably to vaccine therapy.

Urticaria Elicited by Heat, Cold or Pressure.—Urbach and Fasal reach the conclusion that the question whether urticaria elicited by cold, heat or pressure is caused by a vaso-allergy or a vasoneuropathy cannot be answered in general but has to be decided in each individual case on the basis of clinical and of experimental investigations. The majority of cases in the authors' material were not of specific allergic origin. The term physical allergy for cases of this nature is rejected by them and they suggest the term vasoneuropathy of physical origin. The therapy should aim at finding and removing the predisposing factors that have led to the pathologic reaction of the vessels and to the sensitization. Then attempts should be made to increase the tolerance for the physical factor to which the patient is hypersusceptible. Whether the realization of the desensitization may be considered a specific phenomenon of allergic immunity or a nonspecific hypodermic cannot yet be determined although the latter theory has the most in its favor. The authors advise a nonspecific therapy of the vessels by means of a synephrin preparation, synthetic ephedrine or calcium.

Freund's Cutaneous Reaction for Cancer.—Cholewa and Cernele performed the cutaneous cancer test perfected by Ernst Freund and Kammer on fifteen patients with tumors and on twenty-seven control persons. The crystallized carcinoma-fatty acid¹ extracted from the intestinal contents is introduced intracutaneously. The injection never impaired the general condition and did not even produce a disturbing local infiltration. The appearance of a hard and sharply defined nodule (about the size of a lentil) was considered a positive reaction. All the patients with tumors (carcinomas) gave a positive reaction even those with cutaneous cancers without glandular metastases. Of the twenty-seven controls two gave a positive reaction. One of them had diabetes that is, an abnormal metabolism, and the other one was marantic and may have a carcinoma that has not been detected as yet. The authors emphasize that even patients with severe injuries of the liver gave negative reactions. They deplore that they were unable to perform the cytolytic test at the same time.

Adhesive Pericarditis.—Schur summarizes his conception of the pathologic process in adhesive pericarditis as follows. The discharge of the venous blood from the liver, which under normal conditions is subject to a complicated regulation is considerably disturbed. The disturbance is in many cases a

mechanical one but in the majority of cases also a functional one. It consists in the deficient capacity for dilatation of the valve of the inferior vena cava. This factor is the basis for the characteristic stasis, but other factors, particularly the mechanical constriction of the hepatic veins, intensify it. Mechanical and functional inhibitions become manifest especially during inspiration. The discharge from the inferior vena cava is often subject to mechanical disturbances, but the functional disturbance is much less frequent. The superior vena cava likewise may be mechanically or functionally inhibited. Thus the heart is inadequately filled and the beat volume decreases. An increase is made impossible by extracardiac influences since the diastolic dilatation and the progressive dilatation are limited by the adhesions. Moreover, even the reduced quantity of blood cannot be taken care of in the long run because of the disturbed systole, owing to the fact that the masses of adhesions do not permit a normal contraction and that the heart is fixed to the diaphragm and is pulled by it. Hypertrophy is made difficult by deficient nutrition. The decompensation at first only intensifies the hepatoportal stasis, but later it leads to generalized stasis. The author discusses the factors in the development of hydrothorax. It may develop following insufficiency of the right heart and after mechanical and functional inhibitions of the vena cava superior, of the vena cava inferior, and of the vena hemiazygos. The author shows that most of the disturbances are independent from the presence of anterior adhesions and that clinical classifications into internal and external forms are superfluous. He criticizes and rectifies the diagnostic schematization of the size of the heart, rhythm and cardiac sounds and also the significance of Wenckebach's pulse particularly for atypical cases. He calls attention to the slight pulmonary stasis frequently revealed in the roentgenograph and stresses the diagnostic and therapeutic value of electrocardiography. For the treatment of severe myocardial lesions he recommends surgical treatment in several stages and immediate interruption at the first signs of severe disturbances of the heart action. He advises that adhesions with the diaphragm should be removed first, then the cava should be inspected and finally the left ventricle should be freed.

Caesarean Section in Rural Hospitals.—Ludwig reports his experiences with caesarean operations by means of an epigastric incision. He emphasizes that this technic is simple and can be used with one assistant. It requires the smallest incision, it can be completed in a short time, and it reduces the operative shock. It is indicated for the sake of the mother in severe hemorrhages, eclampsia, cardiac disorders, tuberculosis, rupture of the uterus and carcinoma, and for the sake of the child in intra-uterine asphyxia and in prolapse of the umbilical cord. The epigastric incision permits all secondary operations, the delivery of the child is easy and tearing of the uterine wound does not have to be feared. The operation is not restricted to a certain phase of labor and it can be done on the uterus not undergoing contractions. The author performed it between the twenty-eighth and fortieth weeks of pregnancy. The puerperium is uneventful and adhesions of the puerperal uterus with the abdominal scar are prevented. The danger of cicatricial hernias, in the hard-working women of the rural districts, is much less in case of the small epigastric incision than in the hypogastric scars. The author thinks that, in small rural hospitals, epigastric caesarean section should be done in preference to hypogastric section.

Silver Nitrate Reaction in Diagnosis of Diseases of Liver.—Rosa describes the technic of the silver nitrate reaction in the urine. Into five test tubes he puts 1, 2, 15, 2 and 5 cc of urine to which he adds 0.2, 0.1, 0.1 and 0.1 cc of a 10 per cent solution of silver nitrate and then shakes the mixtures. The dilutions thus obtained are 1:5, 1:10, 1:15, 1:20 and 1:50. Under frequent shaking the mixtures are then boiled for from thirty to forty seconds over a strong Bunsen flame preferably in a water bath. Then the test tubes are set up for a few seconds until the precipitate has accumulated at the bottom. In case of a negative reaction the sediment is snow white and above it there is a transparent, yellowish fluid but if the reaction is positive the precipitate is black, brown or black and above it there is a fluid of the same color. According to the severity of the pathologic process the reaction is positive from the first to the fifth tube and in the severest

cases even a 1:100 dilution gives a positive reaction. The author obtained a positive reaction in all cases in which the function of the liver and the sodium chloride exchange were disturbed. Since the disturbances in which the reaction was positive were either liver diseases or processes in which involvement of the liver can be assumed such as uremia, pernicious anemia and syphilis, the author thinks that on the basis of his 2,000 tests he is justified in concluding that the liver plays a part in the sodium chloride exchange. He also deduces from his observations that the lower limit of the normal chloride concentration is 0.72 Gm per hundred cubic centimeters and that the positive reaction of the silver nitrate test indicates an abnormally low chloride concentration of the urine as the result of a serious functional disturbance of the liver. He emphasizes that the silver nitrate reaction is a rapid and simple method and that, whenever it indicates a chloride concentration of the urine of less than 0.72 Gm per hundred cubic centimeters an impairment of the liver exists.

Is Intravenous Pyelography a Functional Test of Kidney?—In summing up the results of his studies on intravenous pyelography, Olivet points out that the absence of a clear contrast in the elimination pyelogram does not necessarily indicate a diseased kidney, for extrarenal causes may retard the elimination so that the renal pelvis does not show in contrast. He states that it is erroneous to consider an extraordinarily clear elimination pyelogram a sure sign of a normal kidney for in contracted kidney and in many cases of chronic glomerular nephritis the elimination pyelogram may still be good at a time when there are already clinical signs indicating renal impairment. The author reaches the conclusion that intravenous pyelography and the determination of the specific gravity of the urine after the injection present a valuable supplement to the formerly employed functional tests, if used together with these elimination pyelography is valuable, but employed alone it is not a reliable basis for the diagnosis.

Histamine for Functional Test of Lung—Klein and Nonnenbruch show that by the subcutaneous injection of 1 mg. of histamine the functional capacity of the lung, namely, the oxygen diffusion, can be determined. They use the following method. While the person is completely quiet blood is withdrawn from the radial or brachial artery the histamine is injected and twenty minutes later another blood specimen is withdrawn by arterial puncture finally about forty minutes after the injection a third specimen is taken. It is sufficient to withdraw 3 cc. of blood for each analysis. Care must be taken that the blood does not come in contact with the air. The specimens are tested for their oxygen deficit, oxygen capacity, percental oxygen saturation and absolute oxygen content. In healthy persons histamine injection is followed by only a slight increase in the oxygen deficit of the arterial blood usually not exceeding from 0.5 to 0.8 per cent by volume. A reduction of the percental oxygen saturation and of the absolute oxygen content in the arterial blood is almost never observed in these

cases. However, if the functional capacity of the lung is impaired (in pulmonary diseases and in disturbances of the pulmonary circulation), the increase in the oxygen deficit is nearly always in excess of 1 per cent by volume, usually from 3 to 4 per cent, and occasionally as much as 5 per cent. Moreover, these cases generally show a considerable reduction in the percental oxygen saturation, which from the normal value of over 92 per cent may decrease to 80 and even 70 per cent, and the absolute oxygen content likewise decreases. The oxygen capacity of the arterial blood, which under the influence of the action of histamine generally shows a considerable increase, does not influence the oxygen content and the percental oxygen saturation. The oxygen capacity, the erythrocytes and the hemoglobin increase in the arterial blood under the action of histamine in the majority of cases. In certain pathologic conditions (edema, impairment of the liver), the oxygen capacity does not increase, or becomes reduced. The authors emphasize that the histamine test as employed by them makes manifest latent disturbances of the pulmonary function in diseases of the lung (pneumothorax) and in disturbances of the pulmonary circulation in that under the influence of histamine a formerly normal oxygen saturation of the arterial blood turns into a noticeable deficit of oxygen saturation.

New Hemophilic Family Tree—Fomio gives the history of a hemophilic family in which the disease has been hereditary for only two generations. How the hemophilic heredity entered this family could not be definitely determined. The author considers it possible that the mother of the grandfather may have brought it into the family for she was of illegitimate birth and may have been related to a hemophilic family. Another possibility is the new development of the hemophilic hereditary factor perhaps as the result of considerable inbreeding. The author reports his studies on the blood, particularly its coagulation, of the last generation and on two women who had carried the disease. In the two women he discovered a slightly prolonged coagulation time, a normal or increased number of platelets and a relative lymphocytosis but whether these are signs of a latent hemophilic heredity cannot be determined as yet.

Atypical Course of Myocardial Infarct—Hochrein and Seggel, in studying the clinical histories of seventy patients with myocardial infarct discovered that the classic symptomatology with stenocardial complaints or circulatory collapse is to be detected only in some patients. In other cases, of which twelve were controlled by a necropsy, the anginal pain had been absent, and in many others also the circulatory collapse. This atypical course of myocardial infarct is found in patients who have suffered from circulatory insufficiency for a longer period. In these patients the development of the myocardial infarct becomes manifest in a suddenly developing dyspnea, in exacerbation of the cardiac insufficiency and in similar symptoms. Diabetic patients represent another group. In these patients, coronary occlusion occurs as a rule without stenocardia while collapse manifestations are comparatively frequent. Since, however, the other symptoms of myocardial infarct such as increased temperature, leukocytosis and circulatory disturbances, are found in the atypical course the authors designate the form occurring in circulatory insufficiency and in diabetes as the clinically rudimentary form of the myocardial infarct. They give a short discussion of the mechanism of this rudimentary form. They point out that the diagnosis of the atypical form of myocardial infarct is generally more difficult than is the case with the classic course; however, the great motor unrest characteristic for all patients with myocardial infarct and also the unusually low blood pressure and the high pulse rate should make the observer think of myocardial infarct. Electrocardiographic examination is necessary for the exact demonstration. The present status of electrocardiography not only aids in the diagnosis of myocardial infarct but also permits the localization of the myocardial lesion and indicates its duration. The differentiation of the incipient and of the late stage is important not only for the diagnosis but also for the treatment for in acute myocardial infarct precaution has to be used in digitalis therapy on account of the danger of acute heart failure from ventricular fibrillation. Even if myocardial infarct is followed by a mild cardiac insufficiency (congestion bronchitis

liver stasis), digitalization should be postponed as long as there are an elevation of temperature and leukocytosis, and as long as the electrocardiogram shows signs of the initial stage

Ascarids in Biliary Tract—Gasinski reports a case of ascarids in the biliary tract in a woman, aged 28, who five weeks before the delivery of her third child had localized pains under the lower right ribs. The pains radiated toward the back, about the right scapula, and presented a paroxysm occurring every day. There was no vomiting at the onset of the illness. The temperature was always 102.2 F and accompanied by chills. Ten years previously she had typhoid. Examination showed that the skin of the abdomen was flabby and nearly always painful on pressure, the liver was enlarged reaching from two to three fingerbreadths below the arch of the ribs, and the gallbladder was slightly distended. The specific gravity of the urine was 1.025 and it contained albumin and some white cells stained with bile. The blood showed hemoglobin 70, red cells 4,430,000, white cells 10,000, lymphocytes 76 per cent, monocytes 22 per cent and an absence of eosinophils and basophils. Further examinations, every two or three days, showed an increase in the white cells (14,000, 15,600 and 16,900). During this time the temperature remained at 102.2 F and the pulse was 120, and during the last few days the patient vomited bile. The author concluded that the gallbladder was inflamed and decided to operate. He found the liver enlarged and studded with small disseminated and soft yellow growths the size of a grain or a bean. The gallbladder was empty and small. Its walls were smooth, thin and shiny. The author aspirated a few cubic centimeters of turbid bile from the biliary canal, in which he found on incision seventy-eight live ascarids. A drain was left in the biliary canal and brought out at the upper end of the abdominal incision. During the first and second week ascarids were discharged through the drain and the temperature dropped, but the patient acquired pneumonia and died toward the end of the third week. Necropsy confirmed the operative observations.

Tonus of Striated Muscle After Sympathectomy in Spastic Paralysis—Kasumov and other workers performed sympathectomies in dogs in order to study the tonotropic effect of the sympathetic nervous system on the function of skeletal muscles. In four dogs they resected the sympathetic trunk and sectioned the communicating branches on the left side of the abdomen from the diaphragm down to the promontory. Twenty-five days later they exposed the lumbar portion of the vertebral column and sectioned the anterior motor roots from the fourth to the seventh lumbar and the first and second sacral nerves on both sides. The observations were continued for several months. The muscle tone was studied kymographically. Before the development of contractures in the course of four or five months, the sympathectomized extremity was found to be weaker than the control extremity. Contractures developed from three to five weeks later on the sympathectomized side and were not so pronounced. Royle and Hunter believed that the plastic component of the muscle tonus depends on the sympathetic nervous system and that in the presence of an injury

to the voluntary nervous mechanism, the plastic tone is raised and spasticity results. The role of sympathectomy, according to them, is to weaken the muscular rigidity and to give the voluntary nervous mechanism an opportunity to take over the control of muscles. The author reports eighteen cases of spastic paralysis of the upper and lower extremities in which Hesse of their institute performed sympathectomies. A good result was obtained in six, an insignificant improvement in nine, and no effect in three. The author concludes that sympathectomy and ramisection, as formulated by Royle, is capable of giving good results in a high percentage of cases and that sympathectomy is the operation of choice in spastic paralysis. It is advisable to employ massage and other mechanical and physical therapeutic methods for a long time after the operation. Patients with a diminished cortical control an abnormal psychic condition and an indifference as to their disease are not suitable for the operation. Ankylosis of joints, deformities of joints and tendons, and too long a lapse between the onset of the disease and the time of operation are not infrequent causes of failure of the operation.

Tumors of Urinary Bladder—On the basis of the material of the urologic clinic of the Moscow Clinical Institute Abramyan and his associates conclude that the incidence of neoplasms of the urinary bladder in the region of Moscow is quite significant and that more than half of these are of a malignant character. Physicians connected with chemical, textile and pharmaceutical industries handling nitro or amino products should familiarize themselves with the symptoms of neoplasms of the urinary bladder. A rational classification of tumors consists of separating them into infiltrating and non-infiltrating growths. The method of choice in treatment of noninfiltrating tumors is electrocoagulation through a cystoscope whenever possible. In extensive papillomatosis, extirpation of the bladder is indicated. In infiltrating tumors located in the fundus or anterolateral aspects of the bladder, partial resection is indicated. In tumors of the trigon area and of the sphincter, extirpation of the bladder with transplantation of the ureters is indicated, provided the disease has not advanced too far and the ureters are not involved. In such instances, it is better not to intervene but to limit treatment to cystostomy, electrocoagulation and chemocoagulation. Roentgen therapy of tumors of the bladder is not satisfactory. Radium is applicable only for control of hemorrhage or in instances of inoperable tumor.

*Lipschutz Cells (Centrococytes) in Lichen Ruber Planus T. E. Olim—p. 788

*Tularemia Its Symptoms and Possible Occurrence in Finland O. Sievers—p. 800

Lipschutz Cells ("Centrococytes") in Lichen Ruber Planus—On histologic examination in ten cases of lichen ruber planus and one of psoriasis vulgaris directly following lichen ruber planus, Olim established the occurrence of "centrococytes" (Lipschutz), i. e., cells whose protoplasm contains single and double granules of varying size, easily stainable with hematoxylin. According to Lipschutz, these granules consist of centrioles which belong to pathologically changed, pluricellular microcentric. In some of the cells, Olim demonstrated simultaneously with the granules a microcentrum of normal kind which, he says, testifies against the centriole nature of the granules.

Possible Occurrence of Tularemia in Finland—Because of the presence of tularemia in the adjacent countries, its occurrence in Finland is considered probable. Sievers tested the ability of 1,062 serums to agglutinate *Bacterium tularensis*. In one case an agglutination of 1:160 took place. Agglutination tests of this serum with the abortus bacillus, typhoid bacilli and paratyphoid bacilli gave negative results. The patient had fever and small swollen glands in the groins. Repeated reactions one week and two months later were positive in the dilution 1:320. Tularemia is strongly suspected although the source of infection and the portal of entry are unknown.

DERMATITIS DUE TO WOODS

CHAIRMAN'S ADDRESS

FRANCIS EUGENE SENEAR, MD

CHICAGO

The greatly increased interest manifested in recent years by dermatologists in external irritants as a source of dermatitis, together with the fact that the exhibit of our section for this meeting deals with that topic, has prompted me to select for the subject of my address a source of irritation which is well recognized, but which appears to me to have greater possibilities than is generally recognized.

My interest in this subject was particularly aroused by the following case:

REPORT OF CASE

G O, a business executive, had been troubled for a number of years with a dermatitis of the hands and feet affecting particularly the toes and palms. He had been treated by a number of dermatologists in New York, Baltimore and Chicago. To his knowledge a fungus had never been recovered from the lesions and several attempts by me were likewise unsuccessful, so that the eruption can be classed only as a recalcitrant eruption of the hands and feet. On March 18, 1932 he presented himself with a different clinical picture, at this time showing a severe erythematovesicular dermatitis of the face, neck, hands and forearms with so much accompanying edema that the eyelids were nearly closed. This condition had been present for two weeks. He stated that he had a similar attack on January 14, which was even more severe, as in this earlier outbreak the popliteal spaces were also involved and the chronic dermatitis of the palms was greatly intensified. He was suffering from acute coriza at the time. This dermatitis persisted with varying intensity but within four weeks was showing some improvement. He then went to Florida, and the acute dermatitis subsided completely within two weeks. He returned to Chicago on March 1, and on March 3 the dermatitis recurred, this being the attack which had persisted until the time he was seen on March 18.

The clinical picture was so obviously that of a dermatitis due to external irritation and the speedy recurrence following his return to his home environment was so suggestive that he was questioned carefully on several occasions but no contacts of a suggestive nature could be discovered. He was asked about hobbies which might bring him in contact with irritants and stated that his chief outside interest was in archery. Questioning about the materials used in the targets showed that he did not handle these. By March 31 twelve days after his first visit the dermatitis had largely subsided but he returned five days later with a severe recurrence of two days' duration. On this occasion having had external irritants distinctly in mind during the interim he volunteered the information that

he had been scraping his archery bows just before the last attacks, and then recalled that he had been similarly occupied just before the two preceding attacks as well, and that the exacerbations during these outbreaks had followed the same procedure. He had on his own initiative applied some of the sawdust moistened with water to a relatively uninvolved area on the forearm and when seen twenty-four hours later showed a strongly positive reaction. This was repeated, the sawdust of white pine being used as a control. The latter gave a negative reaction while the sawdust from the block of wood from which the bows had been made caused a definitely positive reaction. The dust of the same two woods was soaked in alcohol and the tests repeated with the same result, except that the positive reaction was in this instance much stronger.

The patient stated that when working with the bows he usually perspired freely, and so was asked to apply the dry sawdust to the moist skin when perspiring. He did this a few days later, applying the dust to the left forearm, which was less intensely involved than the right, and after this application the dermatitis became more severe on the left forearm than on the right.

COMMENT

The best archery bows are said to be made from the wood of the yew tree, and it was this wood, imported from England, which had been used in this instance.

The fact that dermatitis due to contact with woods and their dusts may occur is well recognized, but this has applied principally to various exotic tropical woods. Pusey has recently had a case of dermatitis occurring in a carpenter which was found to be due to contact with the sawdust of the common poplar, and Levin lately reported a case in which sawdust used for sweeping was the irritating agent. The wood or woods from which this sawdust was obtained could not be determined in this instance, but it is probable that it came from native woods.

My experience with this case led me to examine the literature dealing with this source of dermatitis, and I was impressed with its wide scope, as evidenced by an abundance of articles dealing with different woods and various phases of the subject. No one of these, however, included all of the woods which have been reported as capable of producing a cutaneous response or the variety of ways in which the contacts occur.

That this subject is not new is shown by the fact that according to Fovama¹ one of the earliest known cutaneous diseases in the Orient was dermatitis due to contact with the milky white juice of *Rhus vernicefera* or the Japanese lacquer tree for as early as the seventh century A. D. a Chinese medical book ("Ping-Yuan-Hon-lun") gave a full description of the disorder. Modern attention however seems to date back only to 1893 when Jones² described dermatitis among shipyard workers employing exotic woods and Sternberg² reported cases among cabinet makers in Vienna using the same type of woods.

Read before the Section on Dermatology and Syphilology at the Fifth Annual Session of the American Medical Association, June 14, 1933.

1. Fovama, J. L. "Dermatitis due to contact with the milky white juice of *Rhus vernicefera* and their use." The Journal of the American Medical Association, 1933, 101, 101-102.

2. Jones, J. L. "Dermatitis due to contact with exotic woods." The Journal of the American Medical Association, 1933, 101, 101-102.

The importance of contact with woods and their dusts as a source of dermatitis is attested by the attention given to the subject by various officials in reports dealing with industrial hazards probably the most important of which is the report on poisonous woods by the International Labor Office at Geneva and by the fact that in some countries the effects of certain of these woods are brought under the workmen's compensation acts, notably in the case of West African boxwood, the effects of which are brought under the act in Great Britain British Columbia New South Wales and Minnesota. In the judgment of the Imperial Insurance Office in Germany these morbid conditions were regarded as industrial diseases rather than as accidents. Among the woods which have received official attention from the industrial standpoint are coco-bolo, satinwood, teak, mohwah, lemon wood, acacia, Borneo rosewood, olive wood, cocos wood, sabicu and partridge wood.

Because of the industrial aspect greatest attention has been given to those cases in which the dermatitis has resulted from contact with the dusts produced in working with the woods themselves but eruptions have occurred from contacts of other types. In several instances proximity to the tree alone is said to be sufficient for the production of a dermatitis, this being the case with *Eucalyptus hemiphylloia* and *Eucalyptus maculata*,³ *Aroera*⁴ and *Comocladia dentata*.⁵ Toyama¹ showed how this may be possible as 0.0000015 cc of urushiol, the toxic agent of the lacquer tree, can produce a dermatitis when applied to the skin in a drop of oil and small amounts of the sap can be carried by wind dust or insects. Smoke from the burning branches of the mango tree⁶ has been recorded as producing dermatitis. Contact with any part of the tree is sufficient in the case of these trees as well as with the various types of rengas woods. Upwich⁷ described an instance in which two companies of soldiers were affected after wading in a river the banks of which were covered with rengas trees apparently due to contamination of the water by fruit which was exuding latex. Persons living in houses constructed of *Aroera* have been affected by the timber, and the use of furniture made from rengas has produced dermatitis especially when the furniture has become worn. Contact with bark particularly in stripping, is another method of exposure as with *Eucalyptus macrohynchus*, *globulus* and *hemiphylloia*,⁸ *Melaleuca*⁹ and Brazilian walnut.¹⁰ In some cases the action of the bark is due to the chemicals contained, while in other instances it is said to be merely the mechanical result of the irritating effect of spicules of the rough bark.¹¹ Handling of either the juices or the wood itself is productive of dermatitis in the case of *Anacardiaceae*, such as *Melanorrhoea mangaya* and *curtisii*, *Melanochyla auriculata*, *Gluta*, *Mangifera kemanga*¹² and *Dysoxylon richii* and *muelleri*.¹³ Maiden¹⁴ reported dermatitis ("tea itch") from the climbing of trees of the *Melaleuca* species.

While handling some of the woods in any way may give rise to an eruption, many writers emphasize the

fact that other woods are toxic chiefly or only when there is contact with the sawdust or powder, as from sandpapering. This has been noted in regard to macassar wood,¹ teak,¹⁵ Brazilian walnut,¹⁷ blackwood,⁶ and *Murapannia*.¹⁸ The majority of cases of dermatitis from woods occurs in those whose occupations bring them in contact with the dust and sawdust derived from the woods. The number of woods capable of causing trouble in this way is surprising although, as is to be expected there is a marked variation in the frequency with which different woods produce the eruptions and as a rule the more common offenders are of tropical origin, while the woods of temperate climates are only occasionally at fault. This is probably because trees of temperate climates contain such minute amounts of the toxic agents.² Toyama¹ found that in general the toxicity of a wood is proportional to the amount of toxic substance contained, and this explains the reason for the greater irritating effect of the Japanese lacquer tree as compared with other types of lacquer trees, such as those of Formosa, Indo China and Burma. On this basis it is to be expected that different lots of the same wood might result in a varying incidence of toxic manifestations, and Auld¹⁰ has shown for satinwood that there is great variation in the amount of alkaloid in different specimens. Furthermore, the toxicity of closely related species of wood may vary according to its source for it has been said⁹ that coco-bolo wood from Panama will produce dermatitis, whereas that from Nicaragua will not, and Brigalow itch from handling *Acacia harpophylla*¹ in Queensland is well known in some parts of the country, and unknown elsewhere.

As one report states, the precise origin of the toxic effects of woods does not seem in general to have been accurately determined. In some cases the irritating factors have however been accurately identified. Mathes and Schreiber¹² expressed the belief that irritation from woods is due to nonsaturated resinous acid in a free state, while Czimatis and Hageman² stated that from the chemical standpoint resinous oils and alkaloids are responsible. In the case of *Hippomane mancinella* a glucosidal substance isolated from the sap seems to be the active poisonous principle. From *Peroba anarelli*¹⁹ a group of irritating alkaloids, called aspidospermine has been isolated whereas the resins are secondary factors. The turpentine and essences in the reservoirs and secretory ducts of the hemlock spruce and Norway spruce are blamed. Auld¹⁰ spoke of the resin of *Chloroxylon swietenia* or East Indian satinwood, as usually nonirritating, but he has isolated an alkaloid known as chloroxylon as the irritant. The resins may on the other hand provoke a dermatitis in those who have been previously irritated by the alkaloid. In the case of cocos wood a resin is said to be at fault. Iwakawa²⁴ found that the fissures and cavities of the Tagryasan nut tree contained a sulphur yellow powder from which the irritant substance chrysophanhydroanthron, a substance allied to chrysarobin, was obtained. Brigalow itch is said to be due to a fine yellow powder found in the bark of the Queensland

maple²¹ Friese¹⁸ incriminated acids, saponins, phenol and alkaloids in the various Brazilian woods

That a purely mechanical action may be responsible at times is suggested by Blaisdell's² statement that it is the dust of the woods continuously ground into the skin, rather than the juices, which causes the trouble, while the *Hardwood Record*²⁶ reported that workmen in mills where paper birch logs are used often suffer from a cutaneous eruption which is due to the fine powder on the bark. The dermatitis is attributed to the clogging of the follicles and not to any poisonous properties of the bark. Such a factor may be operative in some instances of wood dermatitis, but surely the vast majority of cases are due to the chemicals contained in the woods. In all, I have been able to find about fifty woods in which the nature of the irritant is described, although the exact chemical nature has not been determined in many of these.

As is the case with dermatitis venenata in general, the duration of exposure before the development of sensitivity is variable. Schwartz¹⁷ reported the incidence of dermatitis from the dust of Brazilian walnut in eleven cases, the reactions in the affected persons beginning within from twelve to fourteen days after they started to work with the wood. With satinwood, Gardner's² patient was exposed for only one week before dermatitis developed, while Jones²⁸ reported exposure for six weeks and Meachen²⁹ for three months. One of Wechselmann's³⁰ patients required only four days of exposure, while three others, less severely affected, had been exposed for from ten to fourteen days. Maiden¹³ reported effects after four days of exposure to *Dysoxylon muelleri*, MacKee,³¹ after two months' work with coco-bolo wood, and Buschke,¹⁹ after five months' work with macassar wood. At the other extreme, Gougerot and Blamoutier's³² patient had worked with various woods for fifteen years, and with violet chony, the cause of his eruption, for two years, while MacPherson³³ reported a case of sensitization to Queensland maple in which the patient had been more or less exposed to the wood for twenty years. Brugel and Perutz³⁴ also reported years of exposure to alderwood before the development of sensitivity. In general, however, the reports indicate that the eruptions usually occur within from a few days to a few weeks after the first exposure to the woods, particularly with the tropical varieties.

In regard to any individual attack symptoms as a rule follow within a short time. The patient usually has sensations of itching or burning at the time of contact, or a few hours later, and the dermatitis appears on the evening of exposure or the day following. Crocker³ reported the development of dermatitis within two hours after exposure to cocos wood. Cash³⁵ in an interesting experiment applied chloroxylon from satinwood to the skin of his forearm with no effect. Ten days later he made a second application, and a dermatitis developed only after twenty-two days had passed. One month later he again applied the alkaloid

and on this occasion the eruption appeared within forty minutes. He stated that in industrial cases a period of latency of twenty-four hours is usually present before the development of reactions.

In the case of the majority of the woods the poisonous effects are most intense or present only with freshly cut wood but this is not the invariable rule. Maiden¹³ stated that the seasoned wood of *Dysoxylon muelleri* is more toxic when seasoned, while Hornsey³⁷ reported dermatitis in persons who had sat on branches of the rengas which had been cut and dried for months and the use of this wood for the manufacture of furniture has practically ceased because of the production of symptoms by furniture which has been in use for years. In fact, reactions affecting the mucous membranes were noted particularly when the furniture became old, worn-out and dusty, according to Ridley¹⁰.

As to the incidence of dermatitis from contact with woods, few figures are available. Schwartz¹⁷ found dermatitis resulting from the dust of Brazilian walnut in 11 of about 100 workers. He communicated with other firms using the wood, and 9 of 10 reported instances of eruptions apparently attributable to the Brazilian walnut, the number of workers affected in the different factories varying from 1 or 2 to a majority, and one firm reported that it had discontinued the use of the wood because of the large number of workers affected. Bassewitz⁴ estimated that from 5 to 10 per cent of the population was affected by the wood of Aroeira, a South American tree. Pflanz³⁸ stated that reactions developed in all workers with moahwood. Ridley¹⁰ found that few if any persons were able to handle the melanorrhæas and glutis of the family Anacardiaceæ without trouble. It is obvious however, from the relative frequency of reports dealing with such woods as satinwood that sensitivity occurs frequently with some, while the infrequent or single mention of other woods indicates that reactions to them are exceptional.

Various types of eruptions have resulted from contact with woods and other dusts. Aroeira⁴ is said in some instances to give rise to a morbilliform eruption. According to Prosser White,¹ prolonged exposure to the effects of *Sarcocephalus dierckhæi* may give a yellow color to the skin and a camphor odor to the breath. Thorns of *Buxus sempervirens*⁴⁰ produce what is termed by Cleland a scaly epithelioma, while splinters of the Australian lacewood are said by Bancroft⁴¹ to have been reported as giving rise to unusually painful wounds "as bad as a snake bite, but he believed that this is an exaggeration. Brugel and Perutz³⁴ reported that occasionally the eruption produced by the alder resembles lupus erythematosus. Livet⁴² thought that basket makers working with chestnut wood developed herpes labialis from the wood. Sternberg⁴³ found an urticarial type of eruption from Indian rosewood and Friese¹⁸ spoke of a "nettle rash" type of eruption from trees of the family Leguminosæ. Iwakawa³⁶ has described a gunpowder-like pigmentation of the skin as one of the effects of the wood of the *Fraxinus montana* tree. Horand⁴⁴ described changes of the skin of the

⁴⁴ Horand, *Gaz. d. M.* 50: 25, 1907.

hands, aptly described by the term "crocodile hands," which he found common among workers with chestnut, and which he attributed to the action of coloring matter in the bark. The ingestion of the lacquer from *Rhus vernicifera* gives rise to a scarlatiniform eruption which Toyama⁴ regarded as an indication of a specific effect of the toxin on the skin. The latex of *Hippomane mancinella*, when fresh, is caustic as is that of *Plumeria rubra*, according to Bretin.⁴

All of the foregoing types of eruption are of the specialized and unusual varieties. In the vast majority of cases, on the other hand the cutaneous reaction is the usual picture of dermatitis venenata and may present simply an erythema although as a rule the outbreak is of a more severe grade with vesicles, bullae and at times pustules. Edema is usually an outstanding feature of the attack and many writers emphasize an erysipelas-like appearance as a striking feature. The follicles are not particularly affected for only in the case of macassar wood¹ was such a localization cited. As is to be expected, the face, neck, hands and forearms are the sites usually involved and the genitalia are affected rather frequently. In some instances the dermatitis extends far beyond the contact areas and may become generalized, as noted with rengas woods by both Hornsey¹⁰ and Ridley¹⁰ and with macassar wood by Buschke.¹⁰

The noxious action of practically all woods is increased when the patient is perspiring and in some instances dermatitis is produced only when the patient's skin is moist. A number of observers have called attention to this, and Ridley¹⁰ in stating that he believes rengas poisoning affects most those who perspire most, recalled that the poisonous oil in *Rhus* is converted into a black nontoxic lacquer by alkalis, he stated the belief that when the perspiration is alkaline in reaction, the action of the toxic agent may be prevented by its conversion. An oily skin has likewise been found to be a predisposing factor.¹⁷ In some instances the wood has been noted to be more harmful when moist as in the case of oak⁴⁶ and Brazilian walnut.¹⁷

With the majority of woods producing dermatitis there are noted reactions in other parts of the body as well. Next to the skin the mucous membranes are most frequently mentioned. Conjunctivitis with intense lacrimation, at times iridocyclitis and even keratitis,²⁴ sneezing, increased nasal secretion, epistaxis and pharyngitis are seen in many cases. Involvement of the respiratory system may be evidenced by dyspnea, bronchitis and asthmatic and "influenzal" attacks. Headache, lassitude, dizziness and fainting spells, nausea, vomiting, fever, urinary disturbances and paresthesia are among other symptoms produced, together with palpitation, sweating and chills. The general reactions are particularly severe in those affected by West African boxwood and at times paralysis of the motor nerve endings results from the action of the alkaloids of this wood. The symptoms of poisoning by jacareuba¹⁸ include dermatitis, thirst and oliguria, and these may be brought back months after an attack by the application of an alcoholic extract of the wood to the skin of the forearm. Friese¹⁸ stated that andiroba produces photophobia and a feeling of heaviness of the limbs, while poisoning with several Brazilian woods of the family Sapotaceae causes falling of the

hair. Wechselmann³⁰ reported insomnia as one of the symptoms of satinwood poisoning. Pardo-Castello stated that the sap of *Hippomane mancinella* is so toxic that one drop of it placed in a wound on the foot of a rabbit or a guinea-pig causes death within a few minutes. There is a legend to the effect that those who sleep in the shade of the tree do not awaken, and it is known to the natives as the "tree of death."⁴⁵ In fact, some of the tropical woods which have not been reported as giving rise to dermatitis may produce these general reactions. Friese, in his report on 626 cases of intoxication from Brazilian woods, found the air passages affected in 184 cases (29.4 per cent), the skin of the hands and feet in 181 (28.9 per cent), the nose and eyes in 163 (26 per cent), the genitalia in 49 (7.8 per cent) and the circulatory system in 49 (7.8 per cent).

Once a person has become sensitized to the woods or their dusts the future course is not always the same. With satinwood Cash²⁷ said that the affected workers may be divided into classes. In the first, after a primary attack of dermatitis, the affected persons are able to resume the same work without further trouble, while in the second group relapses occur immediately on the resumption of work and the men are obliged to abandon the workroom in which satinwood is prepared. Cash himself has not seen any persons who have been able to resume work, but Wechselmann³⁰ and Jones²⁸ have recorded such instances. Friese¹⁸ found that patients affected by pao ferro or others of the family Caesalpiniaceae, became increasingly sensitive, while *Cabuna*, *Aroeira* and *Gonçalo-alves* gradually produced immunity. Schwartz¹⁷ found that some of the men affected by Brazilian walnut if they continued work, developed a tolerance in a few weeks and recovered completely, while others could not continue. Little⁴⁹ commented on the frequency of lacquer dermatitis among foreigners, but found that immunity was acquired by the workers. Practically all apprentices react at first, she stated, but as they continue work the sensitivity diminishes. If they stop work for a few weeks, a slight reaction lasting only a few days occurs on the resumption of the occupation. No immunity to the fig is developed, according to Berlin.⁵⁰

That a sensitivity once developed is often lasting is evidenced by Friese's observation that workers irritated by woods of the Ipe group develop recurrences on resuming work many months later, and John⁵¹ described the case of a worker with dermatitis from teak who had a prompt recurrence on resuming work four years later. Friese also observes that the colored races are more sensitive to the effects of trees of the Ipe group.

Patch tests have furnished valuable aid not only in establishing the diagnosis, but in determining the particular irritants present in the different woods. The moist sawdust is usually sufficient for this purpose, although in some instances it may be necessary to use alcoholic or ethereal extracts. When patch tests are negative, the reaction in some instances may be due to the use of old woods.

There is considerable diversity of opinion as to the nature of the reaction producing the dermatitis and other symptoms. Some writers, as Wechselmann, believe that the condition is distinctly allergic and due

to the biologic action on the cells rather than to a chemical irritation while others as Low,² believe that the sensitization is purely physical or chemical, and that neither immunity nor anaphylaxis in the true or physiologic sense is obtainable. Czinnatis and Hageman²² expressed the belief that in some instances there is idiosyncrasy and in others an anaphylactic hypersensitization, they did not agree with Wechsellmann that all cases can be classed as anaphylactic. Brugel and Perutz believed that in the case of alder the reaction was on an allergic rather than a contact basis. Oppenheim reviewed Wechsellmann's opinion and felt that further investigation was necessary to prove that the reaction is truly anaphylactic. Touton³ stated that idiosyncrasy is due to an antibody-antigen reaction, and recalled that Doerr had said that idiosyncrasy is a part of anaphylaxis, and that the experiments of Prausnitz and Kustner have demonstrated this. Several writers, including Lagrange,⁴ Brugel and Perutz¹⁴ and Gougerot and Blamoutier,⁵ have discussed hemoclastic crises as a result of exposure to woods. In the case of Gougerot and Blamoutier the patient had been working almost exclusively with violet ebony for two years, and with other woods for fifteen years. He took his first vacation in ten years and on returning to work, after an absence of two weeks, developed on the second day a severe dermatitis. After his recovery he was tested with the dust of mahogany and then walnut without result but within twenty minutes after the application of dust of violet ebony, the leukocytes fell from 8,400 to 6,200. Itching began at the site of application after two and three-fourths hours, and a dermatitis appeared the next day. Following the application of the dust in the form of a patch test the leukocytes fell from 7,700 to 4,800. Gougerot and Blamoutier felt that they had been able to desensitize their patient by the application to the unbroken skin of an alcoholic tincture of ebony in progressively increasing strength. These writers stated that the anaphylactic nature of the eruption is shown by the clinical evolution of the eruption, by its progressive intensity, a shortened period of incubation and by the leukocytic shock, characterized as the most constant characteristic of the hemoclastic crises.

These various observations should lead one, I believe, to accept the common type of dermatitis due to contact with woods and their dusts as allergic, in line with the conclusions reached by Block, W. Jadassohn and others in their observations dealing with dermatitis venenata which were so well summarized by Pusey²³ at the last International Congress of Dermatology and Syphilology.

The International Labor Office²⁴ has recommended hygienic measures to be taken to guard against the toxic effects of woods. It suggests (1) exhaust ventilation to remove dusts (2) suitable covers for mechanics working with wood (3) the wearing of overalls that fit closely about the neck (4) cleansing of all exposed parts after work and (5) no employment of persons susceptible to the handling of irritant woods.

I have not thus far dealt with the type of dermatitis which is most interesting particularly because it concerns common woods. This is the "forest essence" dermatitis or woodcutters' eczema which has been described in France and Italy. Spillmann¹ in 1921 described the case of a young forest worker who after carrying some logs of oak wood which had been cut

some weeks before, developed a dermatitis in the contact areas and later on the genitalia. The patient's grandfather was similarly affected whenever he handled freshly cut oak, and one of his uncles, as well as numerous other villagers, had presented similar eruptions at various times. Spillmann ruled out contact with plants but did not think that the oak bark itself could be responsible, and suggested that the eruption might be due to fungi growing on the bark. In 1929, Longin²⁵ stated that he had seen a case of similar type fifteen years earlier. In that instance the patient was affected only when he entered a forest containing freshly cut wood. The writer stated that the question of other plants being responsible has been ruled out by the fact that patients have been affected while working at home or in lumber yards. Longin emphasized contact with freshly cut wood as important, and declared that the action of the contact is constant, as it is constantly reproduced under the same conditions. Unlike the response to a uniformly irritating plant, as the nettle he believed that a previous sensitization is necessary in the case of forest essence dermatitis, and that this susceptibility, once established, is persistent thus constituting an anaphylactic phenomenon analogous to that seen in hay fever. He incriminated the woods of oak, beech and in one instance, acacia. He stressed the importance of location in diagnosis, the hands, face and genitalia being involved regularly. The dermatitis may vary from simple erythema to a severe vesicular and edematous eruption most marked on the eyelids and accompanied by conjunctivitis. A masklike leontiasis of the face may result from repeated attacks. In 1931, Dubreuilh²⁶ stated that he had seen some cases of this disorder, and attributed it to the bark as boards or the sawdust of the offending woods do not cause any trouble. Oak logs were the causative agents in most of his cases but chestnut logs were responsible in one instance, and the plane tree in another. He like Spillmann did not think that the woods must be freshly cut, as in one of his cases the eruption resulted from handling wood which had been cut and in the open air for one year. He also stated that with a single exception, his patients noticed that the wood caused trouble only when it was moist, attacks occurring on rainy and foggy days, and he believed that this eliminates the theory that the eruption may be due to cocoons on the bark. He confirmed Longin's statement that work in the forests is not necessary, and also pointed out that the eruption may occur without direct contact with the trees although outbreak takes place much more promptly, beginning within a few hours after contact. He supported Spillmann's contention that the factor of personal susceptibility is predominant and that this susceptibility which in his opinion is rare is perhaps acquired, since many patients have developed it only after many years of immunity. Once established the sensitivity is persistent and may even increase.

Lagrange⁴ described a case of this type which he investigated from the standpoint of conjunctivitis. His patient developed dermatitis and conjunctivitis from the carriage and handling of wood. Following recovery from a severe attack of dermatitis he used finely pulverized fresh oak bark in a scratch test on the forearm. At the time of the application the leukocytes numbered 8,400 and two minutes later the count had fallen to 4,200 in seven minutes to 3,600 and in eighteen minutes to 3,400 and in twenty-four hours the patient had

a large and pruritic patch of papular dermatitis at the site of the test

Schulmann and Detouillon,⁴⁰ in 1932, pointed out that dermatitis in wooded districts is probably much more common than is supposed, perhaps affecting 2 per cent of the population employed as woodcutters saw-mill workers cultivators fuel woodcutters charcoal burners and hunters. This type of dermatitis develops slowly, is localized to contact regions, but may gradually become generalized, and can be cured readily, often without recurrences if the patients avoid that type of work.

Apart from these cases, however, they recognized another type in which the eruption develops suddenly and in which recurrences take place on exposure to wood. This type, which they refer to as forest sensitization is due to a state of sensitivity.

They believed that in the first group which they call wood itch or woodcutter's eczema workers having contact with the resins are probably the ones affected and that the irritant action is chemical in persons with an idiosyncrasy. In the forest sensitization group, on the other hand the picture suggests an anaphylactic phenomenon as the outbreak occurs suddenly in a person who usually has worked in the woods for years although in rare instances the attack may take place on the occasion of a first visit to the woods. Following this the sensitized person develops a recurrence whenever he enters the woods, sometimes even without immediate contact. In these cases the onset of cutaneous changes is preceded by a sense of warmth and by choking sensations.

With regard to the active agent in the production of this type, these writers stated that this has not been determined as yet but that it seems to be of a volatile nature and soluble in water. They added the poplar and elm to the trees recorded by other authors as capable of causing this reaction.

Drapier⁴⁹ and Gougerot⁵⁰ have also written on this subject in France, and Tommasi⁵¹ described cases occurring in the province of Sienna Italy. The latter in supporting the theory of sensitization, pointed out that workers who return to labor in the woods after a long absence are apt to develop the dermatitis for the first time. In his hands all cutaneous tests to determine the offending agent have proved negative.

There should also be mentioned in considering the source of eruptions due to contact with woods, those cases due to caterpillars, grubs, cocoons and parasites found on the bark, including *mucor* or *mucedo* and *Aspergillus glaucus*, as described by Touton,⁵² Cleland,⁵³ Foot,⁵² Hall⁵⁴ and others.

SUMMARY AND CONCLUSIONS

A case of dermatitis due to contact with the dust of yew wood is reported.

Dermatitis due to contact with woods or their dusts is relatively common. Woods of tropical origin are most often incriminated, but it is probable that woods of temperate climates give rise to reactions more often than is generally supposed.

Eruptions may arise not only from direct contact but also from proximity to certain trees and woods.

The majority of cases are seen in those whose occupation furnishes contact with woods or their dusts, and

this furnishes an important industrial health problem well recognized by various official bodies.

The toxic agents are most commonly nonsaturated resinous acids in a free state or alkaloids, but other types of chemicals are responsible in some cases.

Development of dermatitis may ensue after contact of from a few days to several years, but in general the eruptions appear after a contact of from a few days to a few weeks.

Freshly cut wood is as a rule most toxic, but in a few instances the wood becomes more toxic on seasoning.

A variety of clinical pictures may result from contact with woods but the usual reaction is an intense dermatitis venenata, often erysipelas-like, affecting the exposed parts.

Perspiration and scabborrhea increase the possibility of reaction.

A number of symptoms due to involvement of other parts of the body, particularly the mucous membranes and the respiratory system, may occur.

In the case of some woods tolerance may be established, but as a rule sensitivity once established is persistent.

The cutaneous and general reactions may be regarded as an allergic reaction.

Forest essence dermatitis, or wood cutters' eczema of France, is reviewed.

A table of woods capable of giving rise to cutaneous reactions is presented.

TREATMENT OF ACUTE INTESTINAL OBSTRUCTION BY SUCTION WITH THE DUODENAL TUBE

OWEN H. WANGENSTEEN, M.D.

AND

JOHN R. PAINE, M.D.

Member of the Department of Surgery, University of Minnesota
MINNEAPOLIS

Of the many hollow tubes which serve the body economy, the alimentary canal is the only one which communicates with the surface at both origin and termination. Advantage has long been taken of this arrangement in dealing with the distended intestinal tube by intubation, when the distention was of other than mechanical origin. The rectal tube and gastric lavage are old and well established therapeutic procedures. It is now twenty-four years since Westermann¹ first used the duodenal tube in the relief of postoperative distention of peritonitis. With the introduction of the smooth tipped duodenal tube for nasal intubation by Levin² in 1921 and satisfactory demonstration of the source of gas in postoperative distention by McIver and his associates³ in 1926 as being largely swallowed air, the relief of postoperative distention through employment of the duodenal tube has become a matter of general practice.

From observations made on the drainage of fluid and gas in enterostomies performed for the relief of

acute mechanical obstruction of adhesive origin one of us (O H W) was led to attempt decompression in such instances without operation. We have frequently noted in instances of complete obstruction of the small intestine that soon after the release of the distention by enterostomy even though the adhesive obstructive mechanism is not freed gas may be demonstrated in the colon on the x-ray film. After such automatic reestablishment of the continuity of the bowel following initial release of the distention by enterostomy the discharge of gas and fluid through the catheter is often minimal.

INDICATIONS

It is immediately apparent that the type of obstruction in which the method might be expected to succeed

time in which the obstructive mechanism continues to operate initial decompression with the duodenal catheter serves to improve the patient as an operative risk.

CONTRAINDICATIONS

From theoretical considerations there are two types of obstruction in which the use of the method is contraindicated, viz (1) strangulation obstruction and (2) acute obstructions of the descending colon with enormous distention of the proximal colon. The latter type is essentially a strangulation obstruction in that the competent proximal ileocolic sphincter usually precludes regurgitation into the small intestine and limits the distention to the colon, necrosis gangrene and perforation occurring in the cecum (the most distensible portion of the colon) unless the colon itself is decompressed.

TABLE 1—Classification and Treatment of Intestinal Obstructions

Clinical Classification	Pathologic Classification	Treatment
A Mechanical 1 Narrowing of lumen 1 Strictures of bowel wall a Congenital { Atresia ↓ Imperforate anus b Acquired { Inflammatory ↓ Traumatic ↓ Vascular Neoplastic 2 Obturation 3 Compression from without (1 specially pelvis and retroperitoneal duodenum)	Simple (except in neoplastic strictures of the colon)	Operation preceded by suction for decompression in late cases except in occlusion of the descending colon
II Adhesive bands { Congenital ↓ Inflammatory ↓ Traumatic ↓ Neoplastic	Simple or strangulation	Suction operation for persistent obstruction and in strangulation
III Hernia 1 External 2 Internal IV Volvulus V Intussusception	Strangulation	Early operation
B Nervous 1 Inhibiting ileus—(Paralytic) adynamic 2 Spastic ileus—Dynamic	Simple	Suction
C Vascular 1 Thrombosis and embolism of the enteric vessel 2 Torsion or injury of mesenteric vessels (Operative or blunt trauma)	Strangulation	Early operation

are instances in which decompression instituted at some other level in the blocked intestinal tube alone suffices in dealing with the obstruction. For years it has been uniform practice at the Minnesota General Hospital in dealing with late cases of acute adhesive obstruction of a simple nature to perform enterostomy. Only rarely in our experience has it subsequently been necessary to release the obstructing mechanism. Simple types of adhesive obstruction in consequence constitute the greatest field of usefulness for the employment of the method. It has been our observation that partial acute obstructions of the small intestine may almost invariably be dealt with satisfactorily by decompression with the duodenal tube alone. In most instances of subacute obstruction whether in the small intestine or in the colon suction with the duodenal tube serves adequately in managing the obstructive phase. And in many late cases of simple obstruction of the small intestine

Apart from these absolute contraindications to attempts at decompression of the obstructed bowel with duodenal suction alone there are a number of relative contraindications. In instances of obstruction due to strictures in the intestine whether of simple or malignant nature it is obvious that a direct attack must be made on the obstructive mechanism no matter whether or not decompression of the acute obstruction can be effected by the duodenal catheter. In instances of complete adhesive obstruction of the lower portion of the small intestine decompression by the duodenal tube alone may fail and after a reasonable trial with suction if x-ray films do not demonstrate definite diminution in distention recourse should be had to enterostomy. The appearance of gas in the colon in a complete obstruction indicates not only a satisfactory decompression but also the automatic re-establishment of the continuity of the bowel.

RECOGNITION OF OBSTRUCTION OF THE POWELL

In the occurrence of loud intestinal borborygmi heard with the stethoscope at the apex of intermittent cramp

4. Wargen, O. H. The Early Diagnosis of Acute Intestinal Obstruction with Comment on Pathology and Treatment with a Report of Successful Cases. J. Amer. Med. Assoc. 1917, 10: 101.

pain, the presence of intestinal colic is established. Though intestinal noises may be heard now and then in other colics or acute lesions of the abdomen, there is no intimate time relation between pain and borborygmi as there is in obstruction of the bowel. Having established the presence of intestinal colic, it remains to be determined whether it is due to organic obstruction of the bowel, food indiscretions, acute enterocolitis or abdominal allergic reactions. On the basis of such general symptoms as the absence or presence of fever, vomiting, diarrhea or progression of symptoms, together with an appraisal of an x-ray film of the abdomen, a differential diagnosis can readily be made.

The diagnosis of acute intestinal obstruction has been discussed at length elsewhere, and only the salient features will be related here. Vomiting is usually a prominent symptom in all acute obstructions of the small intestine, that the conspicuous vomiting of obstruction is essentially regurgitant is indicated in its frequent absence in acute obstructions of the descending colon in which, as has already been stated, the small intestine often does not participate in the distention. Instances of simple obstruction ordinarily present no tenderness or rigidity of the abdominal wall. In strangulation obstructions, with the single exception of intussusception in which the strangulated intestine is within the normal ensheathing cylinder, rebound tenderness may be demonstrated.⁶ In simple obstructions the general condition of the patient is not disturbed till late in the course of the obstruction. The pulse and temperature are usually normal. Patients with strangulation obstruction occasionally exhibit quickening of the pulse early in its course incident to the loss of blood into the peritoneal cavity as well as into the infarcted segment of intestine. With continued vomiting, leukocytosis and occasionally elevation of temperature occur. Diminution of the plasma chlorides, elevation of the non-protein nitrogen in the blood and an alkalosis occur consistently only in high obstructions and then only after persistent vomiting of about forty-eight hours' duration. These occurrences therefore are of no diagnostic value.

IDENTIFICATION OF TYPE OF OBSTRUCTION

When correlated with the clinical signs, the x-ray film is an aid of value not only in determining the presence of obstruction but also in deciding its location as

Fig. 1—A film of the abdomen of a patient with intestinal colic. Limitation of the distention to the colon indicates the presence of an obstructive lesion in the sigmoid flexure (carcinoma). Suction siphonage by nasal catheter is contraindicated in this type of case. Immediate decompression of the colon should be done.

well as in the decision as to whether the obstruction is complete or incomplete. In the alimentary canal of the adult, though gas is normally present throughout, it is visualized on the x-ray film only in the stomach and colon. In the small intestine, the interadmixture between gas and fluid is so intimate that gas cannot be seen except under conditions of stasis when gas and fluid tend to separate out. The visualization of gas in the small intestine of the adult is therefore synonymous with stasis. The stethoscope tells whether it is mechanical or inhibitive (paralytic).

A single x-ray film taken with the patient supine gives more information than plates taken in any other position. It reveals the grade of intestinal distention present and affords fairly reliable evidence as to its location. Roentgen studies made with an enema of barium sulphate, though of great value in subacute and chronic obstructions, are unnecessary and are contraindicated in acute obstructions except in intestinal atresia and where the conjectured presence of an obstruction in the descending colon would appear to need verification by an enema of barium sulphate. In a patient having intestinal colic in whose bowel the distention involves and is limited solely to the colon, as indicated in a film of the abdomen (fig. 1), the diagnosis of obstruction in the descending colon is practically established. If loops of small intestine are distended but gas is also present in the colon, the patient in all likelihood has a partial obstruction of the small intestine (fig. 2A). Almost invariably by the time that the patient with suspected obstruction of the bowel presents himself for roentgen examination, several enemata have been administered, and the persistence of gas in the colon in a patient whose distention is in the small intestine indicates that the obstruction of the small intestine is incomplete. Distention of the small intestine alone without visible gas in the colon means that the obstruction is complete (fig. 3A).

From inspection of the roentgen film of the abdomen, one cannot predict the exact location of an obstruction in the small intestine with the same precision as in the colon. Knowing the normal pattern of distribution of the intestinal coils, as described by Mall,⁷ it would appear that the location of the distended coils would indicate where the obstruction is. The factors that prejudice exact determination of the location of the obstruction by interpretation of the roentgen film are probably these: (1) the shortening of the bowel with obstruction, (2) the increased weight of coils of bowel incident to the collection of fluid within them altering the relative position of heavy coils to their neighbors, the extent of this displacement being limited by the length of the mesentery, and (3) the distribution of gas and fluid within the distended coils, gaseous collections will be readily apparent, whereas a segment of intestine distended by fluid only cannot be detected. On the whole, however, it may be determined with fair accuracy whether the obstruction is in the upper, lower or middle third of the small intestine.

The exact nature of an obstruction is, moreover, less readily determined than its location. In the majority of instances, however, the type of obstruction present can be ascertained with a fair degree of accuracy by correlation of the history, physical signs and the roentgen observations. The correct identification of the precise type of strangulation obstruction present even

5 Wangenstein O. H. Elaboration of Criteria upon Which Early Diagnosis of Acute Intestinal Obstruction May Be Made with Special Consideration of Value of X-Ray Evidence. *Radiology* 17: 44 (July) 1931. The Diagnosis and Treatment of Acute Intestinal Obstruction. *Northwest Med.* 30: 389 (Sept.) 1931.

6 The grade of rigidity present in acute abdominal lesions is dependent on the character of the irritant. Hydrochloric acid is a severe irritant and the greatest rigidity of the abdominal wall observed clinically follows perforation of an ulcer of the duodenum. Perforation of the colon is not attended by such emphatic reflex spasms of the abdominal muscles. When blood escapes into the peritoneal cavity accompanying a strangulation obstruction or in a ruptured tubal pregnancy a grade of abdominal tenderness and rigidity that is distinctly less developed than in suppurative lesions is usually observed.

7 Mall F. P. Position of the Intestines. *Bull. Johns Hopkins Hosp.* 9: 90 1895.

though it may be determined with considerable accuracy, is not of the same moment as the recognition of the type of simple obstruction in that surgical intervention is mandatory in all potential strangulation obstructions. The only strangulation obstruction which may escape detection of the existence of compromise of its blood supply are pure enteric intussusceptions. The cecum as well as the ileocolic, ileocecal and compound (entero-enteric and colonic) invaginations may be recognized even though the precise type present may not be foretold.

Of the simple obstructions, the type of obstructing mechanism present can usually be correctly identified. There are, of course, notable exceptions, as, for example, obstruction of the intestine by a foreign body such as a gallstone, packet of worms or other foreign body. Strictures of the small intestine, whether benign or malignant, may be difficult to identify exactly, but the subacute character of the obstruction, the history, the presence of palpable and visible peristalsis and the occurrence of dilated loops of small intestine as observed on the roentgen film, without serious disturbance of the motility of the small intestine as determined by a barium stasis ray, have sufficed to establish the diagnosis in the few instances that have come under our observation.

As has already been indicated, adhesive obstruction constitutes essentially the important field for decompression with suction-siphonage applied to a duodenal tube. In patients who have previously been operated on, the recognition of the adhesive character of the obstruction is usually readily accomplished. Often the diagnosis may be made over the telephone. Though we have obtained successful decompression in instances of suspected adhesive obstruction of a simple nature in patients who have not presented scars on their abdomens, we have always done so with hesitation and would advocate the procedure in such instances only in partial obstructions. Serious doubt as to the character of the obstruction is indication for determining its nature by operation.

It must also be freely admitted that the exact manner in which an adhesive band kinks the bowel cannot be comprehended without a deliberate exposure of it at operation. The most significant item, however, is definite separation of instances of simple adhesive obstruction from actual or potential strangulations. The presence of actual strangulation, we believe, is invariably heralded by the presence of local physical signs such as rigidity and rebound tenderness. That potential strangulations, such as complete encirclement of a loop of intestine by a fibrous strand without compromise of the blood supply (that is, without hemorrhage into the intestine or discoloration of its wall) may be confused with simple obstruction is readily understandable. When fluid and gas make their way into and distend this incarcerated loop, however, the strangulation features will come into evidence as the blood supply becomes compromised.

MECHANICS AND TECHNIC OF DECOMPRESSION BY SUCTION-SIPHONAGE BY NASAL CATHETER

The rationale of relief of mechanical obstruction with the duodenal tube is adequately explained in that decompression of the distended intestine by enterostomy in the majority of instances of simple adhesive obstruction permits the intestine to reestablish the continuity of the intestinal lumen automatically. It is

immediately apparent that the nearer the drainage vent is placed to the site of obstruction the more adequate and complete is the decompression. One distinct advantage of enterostomy over suction-siphonage by nasal catheter is that the intestinal canal above the obstruction may be used as a nutritive tube during the interval while the continuity of the intestinal canal is being reestablished. Attempts at feeding before the obstructive mechanism has relented, when decompression is effected by the duodenal tube, usually results in recurrence of the obstruction.

The small intestine of the adult is an elastic tube of about 20 or more feet in length. The activity of the pyloric sphincter interrupts the continuity of the stomach and small intestine as a single simple tube. Not uncommonly, however, this sphincter fails to present a physiologic block for decompression of the small intestine by suction when the tip of the duodenal tube

Fig 2—A film of the abdomen of a boy of 8 with incomplete adhesive obstruction. The small intestine is greatly distended but there is gas in the colon (two scybalous masses may also be seen in the hepatic flexure). B film after seven hours of suction (the duodenal tube is about to enter the pylorus). C decompression is practically complete after twenty hours. Small gaseous collections are still present but no intestinal loops are distended.

is in the stomach. A successful decompression of the obstructed small intestine is more certain if the catheter finds its way through the pylorus into the duodenum. We have made it routine practice, therefore, to cut extra holes in the duodenal tube as far back as 10 inches proximal to the tip of the catheter. With the end of the catheter in the duodenum, continuous suction may then be executed simultaneously on both intestinal canal and stomach. It occasionally takes some time for the catheter to enter the duodenum. We have recently been employing a special catheter with a rubber of heavier specific gravity near the tip. After emptying the stomach by suction, we have occasionally been able to intubate the duodenum directly with this catheter. Now and then we have had the patient inhale the fumes of broken pearls of animal nitrate in an attempt to relax the pyloric sphincter.

In the intestine of the intact dog or in the human intestine excised at necropsy, it may readily be demonstrated, following the introduction of air or water into the intestine, that the exertion of suction on one end is immediately appreciated in the same degree at the other end. When, however, a mixture of gas and fluid is present, the difficulty well known to physicists whether dealing with rigid or elastic tubes comes into play. In simple gaseous or fluid distention, the entire intestine may be decompressed almost at once. When segments are found alternately distended with gas and fluid, decompression will be only slowly effected.

The churning action of a turbulent intestine, alteration in the relative position of the coils of intestine as may be obtained by change of posture and massage of the abdominal wall, serve to disarrange the existing collections of gas and fluid within the intestine and facilitate decompression.

The degree of suction which may be advantageously utilized in an elastic tube is limited by the engagement

intestinal distention being precluded by continuous removal of these by the duodenal tube, absorption of fluid from the distended intestine occurs, resulting in confluence of gaseous increments which may then more easily be removed by suction.

In the employment of suction applied to a duodenal tube in the treatment of mechanical obstruction it is important to follow the decompression by x-ray films made at the bedside. Augmentation of the distention no longer occurring because of the removal of swallowed air and fluid excreted into the stomach and duodenum, the intermittent crampy pain usually stops as soon as suction is commenced, although every vestige of discomfort usually does not subside for some time. The bowel having accommodated itself to a certain grade of distention, no pain will be appreciated if there is no increase in distention. Mere cessation of pain, therefore, does not mean a successful issue. Narcotics or sedatives for the relief of pain are deliberately avoided. Hot packs, however, are employed as a routine measure over the abdomen. The amounts of gas and fluid aspirated give some indication as to how the decompression is progressing, but the only reliable evidence is diminution in caliber of the distended intestinal coils. The appearance of gas in the colon in complete obstruction of the small intestine indicates that the obstructive mechanism has relented.

ADMINISTRATION OF FLUID

The detail of the technic of the insertion of the tube and its general management are elsewhere described.⁹ In patients with mechanical obstruction no fluid is permitted by mouth during the time that suction is in force. Fluids are given para-orally in sufficient amounts to provide a liberal daily output of urine (from 800 to 1,000 cc urine per twenty-four hours). From 3,000 to 4,000 cc of 5 per cent dextrose in physiologic solution of sodium chloride usually suffices, given intravenously by the slow drip method. The patient is permitted to suck ice, chew gum or a lemon to stimulate the flow of saliva. Accurate measurements of the fluid and gas removed are always kept. Dechlorination will not occur as long as a liberal output of urine is maintained.

The group of cases in which suction applied to a duodenal tube was employed as the primary mode of treatment has been subdivided into three classes for purposes of analysis, viz (1) those in which decompression was done by suction alone without subsequent operative attack on the obstructing mechanism, (2) those in which decompression was done by suction but operation was subsequently performed because of the conjectured persistence of the obstructing mechanism and (3) those in which treatment with suction was employed but in which operation was necessary to effect complete decompression.

The total number of patients treated primarily by suction is thirty-two. Among this number there were six with recurrences on separate admissions, making a total of thirty-eight decompressions. During this interval, in only nine patients with acute mechanical obstruction of the small intestine was primary operation done. Of this number seven had strangulated external hernias (inguinal and femoral), of the remaining two, one had a stricture of the intestine and the other presented unmistakable signs of internal strangulation.

Fig. 3—Series of flat abdominal x-ray plates made on a patient with complete obstruction of the small intestine due to adhesions to show course of decompression with suction siphonage by nasal catheter. *A* initial plate shows considerable distention of small intestine. There is no gas in the colon. *B* a duodenal tube has been inserted and suction has been applied for twenty-two hours. The stomach is empty and the intestinal distention is somewhat less. The patient has been relieved of all distress. *C* twenty-nine hours after the institution of suction the duodenal tube has passed well into the duodenum and decompression is proceeding rapidly.

of the wall of the intestine in the hole of the catheter where the suction is applied. Even with mild suction, this phenomenon may be demonstrated. We believe that 75 cm of water suction lies within the range of the optimum value.⁸

The time element also affects this issue favorably. The important agents in causing distention of the blocked bowel are swallowed air and fluid emptied into the upper reaches of the intestinal canal. Accretion of

9. Wangenstein O. H. and Paine J. R. Nasal Catheter Suction Siphonage: Its Uses and Technique of Its Employment. Minnesota Med. 16: 96 (Feb.) 1933.

The latter case was the only fatal one in the group in which primary operation was done

The patient was a feeble old lady of 69 years who presented intestinal colic and rebound tenderness. The strangulation had been present for somewhat more than forty hours. The gangrenous segment was exteriorized, and the devitalized intestine was cut away and catheters were fastened into each loop after the skin was closed. The operation, which was done under spinal anesthesia (125 mg of procaine crystals), was completed without event, and just as the wound was being closed the patient stopped breathing. She was resuscitated by artificial respiration but died two days later without having regained consciousness.

There were twenty cases in which decompression by suction alone was done. In this group there were three deaths, two of which occurred some time after decompression had established the continuity of the intestine due to causes unrelated to the obstruction. The remaining death in this group, which is directly attributable to obstruction of the bowel, occurred because we failed to operate. The nature of the obstruction was fully appreciated, but it was believed that the patient's chances were better with conservative treatment until her general condition became more satisfactory. Undoubtedly, after the initial decompression, it would have been wiser to have assumed the risk of operation, knowing the hazard of permitting the gallstones to remain within the lumen of the intestine.

The patient aged 66, was very ill on admission, the picture of obstruction being complicated by the presence of a large sloughing bed sore over the sacrum, the entire gallbladder had sloughed into the intestine and the obstructing packet of

There were eleven cases in which decompression was done by suction but operation subsequently performed because of the conjectured persistence of an obstructing mechanism which was continuing to operate. There was one death in this series, the patient dying of pulmonary embolism seven days after operation.

The poorest results were obtained in the third group, in which treatment was begun with suction but in which operation became necessary to effect a complete

Fig 4—Continuation of series in figure 3. A decompression is fairly complete after fifty-five hours. At this time the duodenal tube was clamped at intervals and clear fluids given orally. B plate taken eleven hours later. There is considerable gas in the cecum and ascending colon indicating that the obstructive mechanism has relented. There are still a few coils of distended small intestine. The patient has had no intestinal colic since.

TABLE 2—Summary of Mortality of Acute Mechanical Obstruction of Small Intestine

	Num ber of Cases	Deaths	Mor tality per Cent	Deaths Unre lated to Obstruc tion	Cor rected Mor tality per Cent
A Treatment by suction siphonage with nasal catheter					
1 Decompression by suction alone	20	3	15.0	2	5.0
2 Decompression by suction but with subsequent operation performed on obstructing mechanism	11	1	9.0	0	9.0
3 Treatment by suction initially but operation necessary to effect complete decompression	7	3	42.8	0	42.8
Total mortality in groups with suction					
Patient mortality	32	7	21.9	2	15.6
Case mortality	33	7	21.4	2	13.1
B Treatment by immediate operation	9	1	11.1	0	11.1
C Other cases					
1 Manual reduction of strangulated hernia	1	0	0.0	0	0.0
2 Patient's moribund on admission	3	3	100.0	0	100.0
Total mortality by patients	4	11	27.5		
Total mortality by cases	31	11	35.5		

gallstones lodged in about the midportion of the intestine never changed their position as frequent subsequent roentgen examination indicated. A partial decompression was effected two hours after the commencement of suction and was complete in forty-eight hours. The patient was free from distress two hours after suction was started. Alternate suction and feeding were continued through the tube for even weeks the patient meanwhile improving. Death was due to perforation of the intestine by the gallbladder and its contained stones. An obviously necessary operation was deferred because of the generally poor condition of the patient. Timely operative intervention might have saved the life.

decompression. Of seven such cases, three were fatal, making a mortality of 42.87 per cent. Two of the patients died, however, because of ill chosen surgical measures for which one of us (O. H. W.) accepts full responsibility. Judging from the nature of the obstruction, as found at operation, we believe that both these patients would have gotten well had conservative treatment been persisted in, or had simple enterostomy alone been done at operation instead of freeing the adhesive mechanism. Undoubtedly one of the chief factors in the continuance of the persistently high mortality of acute obstruction is this anxiety on the part of the operating surgeon to do the operation of election, viz., to undo the obstructive mechanism and restore the continuity of the intestine at once. One can really appreciate, however, that, when a short band has obstructed the intestine for a few days, it frequently becomes actually fused with the intestine, and an attempt to liberate it results in opening of the intestine. Our experience has been that spillage of intestinal content, even though minimal in amount, in acute obstruction usually foreshadows death from peritonitis.¹⁰ The other death in this group was that of a young Mexican woman who was six months pregnant. She had not been operated on previously, and the nature of the obstructing mechanism remained in doubt. At operation a small viable enteric intussusception was found and easily reduced, still the patient died of peritonitis three days later.

On the whole the group of cases in which subsequent operation is necessary on the obstructive mechanism after satisfactory decompression has been achieved are constituted largely by instances of universal adhesions and strictures of the intestine itself. There have been a few instances of adhesive obstruction in which recurrent attacks indicated the necessity of operation.

10 Wangensteen, O. H. Therapeutic Considerations in the Management of Acute Intestinal Obstruction. The Technique of Intestinal and Small Bowel Surgery. Vol. 1. The Technique of Intestinal and Small Bowel Surgery. Arch. Surg. 66: 933 (June) 1933.

at which only single bands were found. Such instances in our experience have not been numerous. On the contrary, it has been remarkable to note how many patients with obstruction of adhesive origin of severe grade have been well without any suggestion of obstructive features after decompression by suction.

In those instances in which a satisfactory and complete decompression was achieved only after the elapse of considerable time (forty-eight hours and more) we failed to observe any manifestations of a toxic influence. Almost invariably the patients ceased to complain of intestinal colic soon after the commencement of suction, although frequently several hours elapsed before the patient was entirely free from distress. There was no acceleration of the pulse on the contrary, if it had been somewhat hurried on admission

with the duodenal tube unaided by other therapeutic measures is recommended for simple obstruction of the small intestine only. The adhesive variety of obstruction in which the establishment of enterostomy permits of automatic reestablishment of the continuity of the bowel is particularly suitable for decompression with the duodenal tube. Strangulation obstruction in which the blood supply of the intestine is compromised and instances of acute obstruction of the descending colon in which the small intestine usually does not participate in the distention are contraindications to the use of the method. Most partial or incomplete mechanical obstructions of the small intestine can be adequately decompressed by this means alone. Some of these will necessitate a subsequent direct attack on the obstructing mechanism itself. In complete obstructions of the small intestine in which the obstructing mechanism does not relent after an adequate trial with suction, recourse should be had to operation (enterostomy).

A diagnosis of obstruction and determination of whether simple or strangulation obstruction is present can be made in most instances with a high degree of accuracy. Whenever there is serious doubt concerning the nature of the obstructing mechanism, operation should be done. The only adequate manner of ascertaining whether a decompression is being obtained is by taking subsequent x-ray films at the bedside.

The true value of suction-siphonage by nasal catheter in the treatment of acute mechanical intestinal obstruction will become apparent only when the method has been given wide clinical trial.

ABSTRACT OF DISCUSSION

DR. ERWIN R. SCHMIDT, Madison, Wis. About a year and a half ago I had an opportunity to watch this method and since then it has been instituted at the University of Wisconsin. I can subscribe to everything that the authors have said. There are certain things that I can add from experience. We have used continuous negative suction in a great number of cases in which we found nausea or vomiting after operation. It keeps the stomach empty, renders these patients comfortable and serves to supply fluids by mouth during the time the patients are nauseated and are vomiting. Poissonnier in France recognized this principle in treating perforated ulcers of the stomach in 1906. This brings me to the second group of cases in which we have used it: those cases in the abdomen in which there has been some question as to the final diagnosis. My belief is that this method is fundamental and should be understood by every practitioner of medicine because it will lead to a more accurate and more careful diagnosis. Most of the mortality and morbidity is probably due to an inadequate examination, understanding and evaluation of patients before they come to operation. This method will give one time to evaluate the patient properly and in that way one will reduce the mortality rate markedly. I believe that as a result of this method the old teaching that an obstruction means an emergency operation is antiquated. In the service with which I am connected an obstruction in the abdomen is no longer considered an emergency operation. By means of this decompression we are able to evaluate patients to find out what their nonprotein nitrogen is, what their chlorides are, what their kidney function is, and then we have a pretty good idea as to what the patient will stand. We use the method not only in the evaluation of patients before operation but also postoperatively. The facts and principles that were presented in this paper are so fundamental that every practicing physician should understand them. They can be used in the home; they can be used in the hospital. If they are properly used in the home it will be possible to carry moribund patients along, transfer them to the hospital properly, evaluate their condition and give the proper treatment.

DR. WILLARD BARTLETT, JR., St. Louis. I have been using this method of decompression of the intestine by continuous

Fig. 5—Diagram of suction apparatus used at the Minnesota General Hospital. The upper bottle is hung by a canvas sling from an irrigation stand. The lower bottle rests on the floor. A Y connection is attached to the duodenal tube so that a syringe may be conveniently used to clear the tube if it becomes plugged. (The C. F. Anderson Company, 214 South Seventh Street, Minneapolis, assembles this apparatus for distribution.)

before the institution of suction it became slowed as the decompression progressed. The general appearance and aspect of the patient usually exhibited improvement commensurate with the diminution of intestinal distention. Even in those instances in which suction was persisted in for some considerable time (group III) but in which a fairly satisfactory decompression failed to establish automatically the continuity of the intestine necessitating resort to operative intervention, there was no suggestion in the patients' appearance or objective signs to indicate a decline in their general well-being.

SUMMARY AND CONCLUSIONS

Suction-siphonage by nasal catheter constitutes a satisfactory manner of dealing with many instances of acute mechanical intestinal obstruction. Decompression

positive suction from the stomach since 1930, with the greatest satisfaction. It is my sincere belief that in the absence of necrosis of the bowel wall, the patient who is treated in this manner together with proper replacement of water, salt and minerals will have a very hard time dying. I am satisfied that he will not get worse under observation but will get into a far better condition to stand a radical corrective operation if such becomes necessary. By keeping track of the intake of fluid by mouth and of the return of fluid from the nasal catheter under suction, one can tell exactly what the physiologic status of the obstructed intestine is as it varies from time to time with progress under treatment. One can tell in terms of cubic centimeters per hour at what rate ingested fluids disappearing from the stomach are returning from the intestine into the stomach. I have taken the pylorus as the landmark and embodied it in this term of polyoric balance in the anatomic, not in the physiologic sense of the word. When these patients are first seen, they are in a state of negative pyloric balance, that is, they are refilling their stomachs from the obstructed intestine. That negative balance diminishes under treatment until a zero point is reached and then, as they recover, a positive balance develops. I will differ with the authors in this one point, that in the patients with obstructing lesions in the left half of the colon the ileocecal valve is usually incompetent and suction treatment at least in certain of them may be successfully and safely used.

DR O. H. WANGENSTEEN, Minneapolis. Only after this method of treating acute mechanical obstruction has been tried in the hands of many practitioners under varying circumstances will its limitations and possibilities become well defined. The method has certain limitations, as the enthusiast will soon discover. When employed judiciously it will obviate the necessity for many operations and when combined with timely surgery in instances in which the method as a sole therapeutic agent is inadequate in dealing with the obstruction, its employment I believe will lead to definite lowering of mortality. It may appear difficult to comprehend the logic of its use in many instances of adhesive obstruction when one contemplates the nature of the interference of the band to the continuity of the intestine. When one recalls, however, that simple enterostomy in similar instances often serves the purpose adequately without a direct attack on the obstructing mechanism itself, one may better appreciate how nasal catheter suction siphonage may be successful in effecting decompression of the blocked bowel. It may not be amiss to remember that it is often one's own fixed ideas that constitute the most difficult hurdles. Two factors that contribute largely to the unwarranted mortality of acute intestinal obstruction are late diagnosis and ill chosen surgical procedure. It is difficult to adjudicate or appraise accurately the sins of omission or commission but I have the firm conviction that a large number of neglected cases of bowel obstruction may be salvaged by critically selected and well executed surgical procedures. In the absence of a strangulation obstruction the operation of least magnitude is the safest and wisest conduct for the patient. In late simple obstruction the performance of an aseptic enterostomy as described here by Drs. Orr and Gatch holds out the greatest hope for the patient. When strangulation is present, the viability of the bowel must be determined no matter how ill the patient devalitized intestine must be excised. Exteriorization with secondary anastomosis in such instances in the usual case is safer than primary resection.

Infantile Paralysis—The first outbreak in the United States was described by Caverly in 1894 in Vermont while Wickham, of Sweden in 1905, first described the mild non-paralytic type of case and recognized the slight infectiousness of the disease. In 1909 Landsteiner and Popper first successfully transmitted the disease to monkeys. During the succeeding years of intensive study of poliomyelitis not a great deal of progress had been made in the prevention and treatment of the acute condition but great advances have been recorded in the restoration of function of paralyzed muscles and much has been added to our knowledge of the extent of infection in the population and the probable methods of spread.—Harriett W. T. Poliomyelitis. How Is It Communicated? *Poliomyelitis* 3:2 (Sept.) 1933.

THE PREHALLUX IN RELATION TO FLATFOOT

F. C. KIDNER, M.D.

DETROIT

In 1929 I¹ described an operation for the correction of certain cases of intractable flatfoot by the removal of the prehallux or accessory scaphoid and transplantation of the posterior tibial tendon. In that article the

Fig. 1—A posterior tibial tendon passing over inner end of prehallux to insert in cuneiform B upper flap dissected off superior surface of the scaphoid, C superior surface of scaphoid

literature was reviewed and a bibliography given. It was stated that the prehallux is a common and frequently unrecognized anomaly which, by changes in leverage, interferes with the normal mechanics of the action of the posterior tibial muscle and thus produces weakness of the longitudinal arch and flatfoot of a type highly resistant to the usual conservative methods of treatment.

Fig. 2—A and C as in figure 1 B lower flap dissected off inferior surface of scaphoid and astragalus

It was also stated that in the presence of the prehallux, whether as a separate bone or as a prolongation inward of the scaphoid there is an abnormal insertion of the tibialis posterior tendon. Instead of passing under the inner end of the scaphoid to insert in the lower sur-

¹From the Orthopedic Clinic of the Children's Hospital of Michigan. Read before the Section on Orthopedic Surgery at the Fifth Fourth Annual Session of the American Medical Association, Milwaukee, June 1, 1929.

face of the two internal cuneiforms and bases of the second and third metatarsals, the tendon is displaced inward and upward to pass across the inner tip of the scaphoid, to which it is attached firmly before finally inserting into the medial surface of the internal cuneiform. This change in course and insertion results in

Fig. 3—A tendon transplanted downward and outward between lower flap (B) and scaphoid. Deep stitch in place. D osteotomized inner surface of scaphoid. B lower flap. C upper flap.

the loss of the tendon's normal suspensory action and transforms it into an adductor of the forefoot instead of an elevator of the tarsus and longitudinal arch. In other words, the proper function of the *tibialis posterior* is that of an inward rotator of the foot around the longitudinal axis, passing through the middle of the head of the astragalus. This function is entirely lost in its abnormal attachment.

It was also shown that the inward projection of the scaphoid, whether united or not, interferes in the full inversion of the foot, either by pinching of the internal lateral ligament of the ankle or by actual impingement on the internal malleolus, which, in time tends to increase valgus, through reflex overactivity of the abductors, in their effort to prevent pain.

Fig. 4—Two flaps sutured over bare bone and tendon.

Since the publication of that paper, my associates and I have continued to study this problem and to employ and improve the operation with increasing success. Certain new points have developed. Most important of these is the fact that many cases of flatfoot in which the prehallux is absent show the same abnormal course of the posterior tibial tendon that is associated

with its presence. The tendon passes across the inner end of the scaphoid instead of under it and thus loses its suspensory function and its mechanical advantage as a support to the longitudinal arch. The second point is the fact that, in the presence of the prehallux, the outward excursion of the scaphoid on the head of the astragalus is increased so that the motion of the astragaloscaphoid joint is abnormally great producing what is, in effect, an outward subluxation of the whole forefoot or an inward subluxation of the anterior end of the astragalus. This leads to a considerable increase of ligament strain with marked pain and foot weakness.

The continued study of this condition has convinced us of its importance in the etiology of a large class of cases of what may well be considered congenital flatfoot. This conviction has led us to employ the operation for its correction as a routine in all cases, whether in children or adults, which present a prehallux, either free or united, or which present a posterior tibial tendon whose attachment is transposed inward and upward.

OPERATION

The operation has been somewhat modified in order to secure a dependable fixation of the posterior tibial tendon in its new bed. It now consists of the following essential steps:

A generous incision, with slight downward or upward convexity, is made through the skin and fascia over the course of

Fig. 5 (case 1)—A before operation. B after operation.

the posterior tibial tendon from a point just in front of the internal malleolus nearly to the base of the first metatarsal. The tendon is dissected clear, through the whole length of the incision care being taken to preserve its attachment to the prehallux and to the cuneiform. From the superior and inferior borders of the tendon two fascial ligamentous and periosteal flaps are dissected outward from the superior and inferior surfaces of the scaphoid and anterior astragalus. The dissection of these flaps, subperiosteally leaves the upper and lower surfaces of the inner third of the scaphoid exposed the tibial tendon still being attached to its inner tip. The inferior flap is carried outward for at least an inch. The tendon is then freed from its scaphoid attachment with a thin osteotome in such a way that the medial fibers are detached from the medial surface of the cuneiform but the inferior fibers are left attached. This leaves the distal insertion of the tendon underneath the long arch and assures a straight line of pull when the tendon is transposed.

It is then possible to transpose the whole tendon outward and downward to the lower surface of the scaphoid. Usually the contour of the lower surface of the scaphoid is such that a natural groove exists for the reception of the tendon. If not such a groove is cut. The inner end of the scaphoid and the prehallux is then removed so that the remaining bone is flush with the astragalus and cuneiform. Bone wax is forced into the raw surface of the scaphoid to prevent new bone formation an unpleasant complication that has occurred. If the inferior periosteal ligamentous flap is strong and firm two number 2 chromic gut sutures are passed, by means of a very short sharply curved cutting needle from below upward, at a

point as far outward as can be reached, through the flap through the tendon, and then down again through the flap to be tied in the sole of the foot. These stitches anchor the tendon three-fourths inch outward from its original position and directly beneath the scaphoid.

The upper and lower flaps are then sutured together with chromic gut, so that the scaphoid is covered and the tendon firmly buried in its new bed. If the inferior flap is weak as a

Fig. 6 (case 2)—Before operation showing prehallux and displaced tendon.

result of the chronic foot strain the tendon is fastened in its new bed by means of chromic stitches passed through two holes drilled through the middle of the scaphoid. In anchoring the tendon, care is taken to see that it is under tension and that the foot is in moderate cavus and supination. The skin wound is then closed and the foot put up in plaster in the overcorrected position for six weeks. This is sufficient time to allow the posterior tibial muscle to take up the slack in its tendon and to allow complete fixation of the tendon in its new bed. Corrective shoes are then fitted and physical therapy and muscle education carried out for another eight weeks. If the case has been a severe one, outside upright braces with inside T straps are worn during this period.

COMMENT

The operation has been uniformly successful in three ways. First, by transforming a perfectly flat foot into one with a good longitudinal arch. Second, by relieving symptoms that were due to foot strain. Third, by removing the unsightly prominence of the inner end of the scaphoid, which is subject to trauma and frequently painful. Power of voluntary full supination always follows the operation.

In 1928, I Zadek published a paper in which he recognized the fact that the attachment of the posterior tibial tendon was often abnormal in the presence of prehallux, but he thought that the tendon ended at its attachment to the inner end of the scaphoid. Actually, the attachment to the tip of the scaphoid is in the course of the tendon which continues on to insert finally in the inner and anterior surfaces of the internal cuneiform and base of the first metatarsal and into the ligaments of the metatarsocuneiform joint. The considerable number of operations we have performed for this condition have given us an opportunity to study the anatomy of the posterior tibial tendon with great care. The textbooks state that the normal course of the tendon includes fibers attached to the interior surface of the scaphoid but that the main attachment is a fanlike arrangement of fibers spreading over the

inferior surfaces of internal cuneiforms and reaching forward to the bases of the second and third metatarsals. The textbooks also state that there is some attachment to the sustentaculum tali. In our operations we have seen all possible arrangements of the insertion from the textbook type to the completely transposed tendon just described. In a frequent variation, the tendon splits three-fourths inch posterior to the scaphoid, one branch inserting into the lower surface of the scaphoid and the other into its inner end.

Speculation as to the cause of the transposition of the tendon is interesting. Evidently the presence of the prehallux does not explain it completely, because it occurs in cases of flatfoot which show no prehallux. There is an interesting analogy between this anomaly and that of the anterior tibial tendon mentioned by Peabody.²

The mechanical disadvantage under which the tendon must work in its abnormal position is often well demonstrated at operation. When the foot is completely supinated and the forefoot adducted, the tendon will seem to wrinkle or fold up longitudinally so that it is pinched between the malleolus and the scaphoid, thus explaining the tenderness and some of the pain.

1337 David Whitney Building

ABSTRACT OF DISCUSSION

DR. CHARLES W. PEABODY, Detroit. During the last five years I was responsible for the work in an independent orthopedic clinic that sees quite a large number of postural defects. Thanks to a very competent physical therapy staff this clinic has been getting prompt and permanent results by the usual program of support and postural reeducation but still there were a certain number that failed to respond. When about four years ago Dr. Kidner called my attention to the anatomic variations associated with what he calls 'prehallux' I found that this anomaly

was roentgenologically at least demonstrable in most of these children that did not respond. Ever since my early acquaintance with Thomas Dwight's monograph on the supernumerary bones of the foot I have been conscious of the existence of his 'tibiale externum' or 'accessory scaphoid' and had frequently been bothered with it in attempting a com-

Fig. 7 (case 2)—After operation showing good arch.

portable fit of the Whitman weak foot brace. I also had noted Sever's article some fifteen years ago on successful relief of symptoms by removal of these bones. But I had never heard of the theory of mechanical interference with the normal supinator function of the tibialis posterior muscle and tendon until Dr. Kidner worked it out and so far as I know this is an original contribution in this respect. Since 1929 I have had the opportunity of operating on twenty-four patients with this condition. In all I have encountered along with the bony abnormality the same deviation in the posterior tibial tendon and with almost the same technic have seen the same elimination of symptoms, objective and subjective. It has seemed to me that the mechanics of muscular control of the human foot places a major burden on the invertors or supinators with the tibialis posterior bearing the brunt of this and I am convinced that Dr. Kidner is right in his proposition that the displacement of the insertion of this tendon which has uniformly been seen to accompany the scaphoid anomaly in all the operative cases tremendously impairs its effectiveness. The definitely localized pain of which many of these children complain and the frequent localized tenderness and swelling are due to the abnormal strain at this point in the attempt at normal function. It may sometimes be due to the chafing of the enlargement against the shoe, with a sort of bursitis over it, or possibly also to a traumatic epiphysitis or apophysitis at this point as at the heel and at the tibial tubercle. The prehallux cases in my series presented both tenderness by palpation and subjective symptoms. The final check up showed absence of pronation in all as contrasted with marked pronation originally. It is my impression that these anatomically had a good arch the pronation being the relatively greater defect that is, a relaxed foot rather than a structural flatfoot and on postoperative check up all showed a normal arch. In fact four years ago the clinic registered 293 cases of defective foot posture. Of that number I made a diagnosis of prehallux in thirty cases or about 10 per cent. Objective symptoms (defects of posture) or pain were present in 24. Operations were carried out in 21.

DR EDWIN W. RYERSON, Chicago. I have operated on a number of patients with accessory scaphoid without in any way realizing the importance of the suspensory power of the posterior tibial tendon and that it was displaced in its insertion. The significance of this should be recognized by all orthopedic surgeons and the paper is a distinct contribution. I feel that in two of the cases in which I simply removed the accessory scaphoid and diminished the internal projection of the scaphoid without transplanting the posterior tibial tendon and binding it to the outer side the unfavorable results were probably due to the point brought out by Dr. Kidner. It occurs to me that in some of the more marked cases of lateral deviation of the foot it might be wise to combine with Dr. Kidner's operation the arthrodesis of the joint between the internal cuneiform and the first metatarsal bone afterward placing the first metatarsal at an angle downward to increase the height of the arch. It is possible that this combination would produce a little higher arch although the height of the arch has no real relation to the capacity of the foot for work. Nevertheless in one or two of the pictures that have been shown it struck me that the foot would be a little bit stronger if the arch were a little higher and the combination of Hoke's operation with Kidner's operation might mean a slight improvement.

DR FREDERICK C. KIDNER, Detroit. I want to thank Dr. Peabody and Dr. Ryerson for their discussions. Dr. Peabody spoke of the duration of after-treatment. I said six weeks in plaster because most of my cases are in a crowded free clinic in which we haven't enough physical therapists to give the necessary time and accurate care that should follow the early removal of plaster. I think that Dr. Peabody is right that three weeks of complete fixation is enough if one has the properly trained physical therapists to take care of the cases in the early stages. Dr. Ryerson spoke of arthrodesis. In one or two cases I have done an arthrodesis of the scapho-astragal joint and in one or two others of the cuneiform-metatarsal joint but those were cases in which the arch had been fixed in rigid flatfoot by long use. I felt that the tendon itself would not be strong enough to lift such fixed flatfoot. In certain cases it is wise to do an arthrodesis in conjunction with transplantation of the tendon.

SUBPERIOSTEAL RESECTION OF THE TIBIAL SHAFT IN OSTEO- MYELITIS

D. M. BOSWORTH, M.D.

NEW YORK

One of the most startling statements that I can remember during my undergraduate training concerned the regeneration of a complete new bone shaft in the young following subperiosteal resection. As I remember it, the source of the experimental and practical work on which this statement was made was not given. Nevertheless the fact that nature could replace such a complicated and necessary structure of such gross size seemed unbelievable. The fact, however, was accepted by me and like many such was not again thought of until September, 1928. At that time the first case herein reported was seen. Previous to this time I had found it a frequent medical rumor that such regeneration could occur but it was not until the literature was inspected following the completion of the first case that the sources of theory and practical application were discovered.

The work of three men, Ollier in 1857, Nichols in 1904 and Phemister in 1915, stood out as major contributions in a rather small firmament. The literature in regard to this subject is very limited if one excludes all reports of tibial defects not due to osteomyelitis and those not consisting of practically a complete diaphysis. Only six men have reported having removed a complete tibial shaft with the expectation of periosteal regeneration and of these only four gave the end results. Haas and Beek mentioned excision of tibial shafts as having been done with the possibility of securing regeneration but they did not report any specific end-results. Ryerson in a discussion stated that he had three cases of successful regeneration of the entire tibial shaft and one failure. Clopton reported four successful cases and two partial failures of regeneration.

Nichols wrote a lengthy monograph applying Ollier's principles of bone regeneration in cases of removal of the tibial shaft for osteomyelitis. He reported in detail three cases of complete removal of the tibial diaphysis with good functional results obtained within from a few months to four years after operation. It is noteworthy that he delayed removal of the tibial shaft for the formation of an involucrum and the inference is that he left it in place. No immediate postoperative roentgenograms were shown so that one cannot be certain whether or not he left the involucrum as a partial supporting structure. He stated however that when collapsing the periosteal tube there was a crackling sensation. This again would lead one to infer that some or all of the involucrum was left inside. He made an important remark regarding operative removal, viz. that whenever possible one should taper the stump of diaphysis remaining attached to the epiphysis at either extremity of the periosteal tube so that no dead space is left. (This was done in all of my cases, necessitating sequestrectomy from the distal portion of the diaphysis in two of them, after almost complete healing of the rest of the wound and beginning regeneration of the tibial shaft.) He mentioned two cases prior to his own in which tibial regeneration occurred—one was done by Cheever in 1870 and the second by H. W.

Read before the Section on Orthopedic Surgery at the Eighty-Fourth Annual Session of the American Medical Association, Milwaukee, June 16, 1933.

Cushing in 1899 Both were in Boston and were locally reported The extent of removal and speed of regeneration were not given, but the final results were reported as complete successes He stated that the best time for such an operation is eight weeks after infection, but, as will be seen from my subsequent case reports regeneration can take place at any period He likewise makes sterilization of the exposed periosteum an important factor (Sterilization, however in a widely infected periosteal tube must certainly be impossible and was not attempted in any of my cases All

article is the basis on which all subsequent work on regeneration of the tibial shaft has been carried out

Animal experimentation with subsequent human operation, based on Ollier's principles and Nichol's practical results, were reported by Phemister in 1915 He went on from experimental and theoretical conclusions to remove a tibial shaft in two cases In a girl aged 3 years he secured a perfect result, with no shortening, two and three-fourths years after operation In his second case, that of a man, aged 45, he obtained practically no regeneration, and though the case was

Fig 1 (K C)—A preostectomy condition of the tibia riddled with sequestrums The epiphyseal plate is involved B complete excision of the tibia C faint line of periosteal regeneration one month after operation This is the slight shadow just to the right of the fibula D new tibial shaft four years after operation E increased size of the tibial shaft following excision of adherent scar

the tubes were formed without disinfection, except once when the infection was so virulent that the periosteal tube was packed widely open) His end-results showed good function, with full weight bearing, through an irregularly shaped shaft, which eventually developed a marrow cavity He reported no failures, or partial failures, such as my last three cases may prove to be Just as successful and safe lengthening of the tibial shaft was first done by LeRoy Abbott, and the principles evolved by him have not been changed, so Nichol's

reconstructed later it must be classed as a failure from the standpoint of the present article

Haas reported no cases but stated that excision of the tibial shaft was followed by restoration of the bone in the majority of cases and advised leaving the wound wide open I feel that one must be warned against such a procedure Removal of a complete shaft and drainage only at the ends of the periosteal tube give sufficient margin of safety in the face of any osteomyelitic infection of the tibia With the periosteal

Summary of Histories of Six Cases

Patient	G B	G C	N H	I N	J S	F W
Age	16 year	8 years	11 years	6 years	7 years	9 years
Sex	Male	Male	Male	Male	Female	Male

tube open there is difficulty in covering the new tibial shaft, which has begun to regenerate on the external surface of the leg

A few writers have advised leaving a portion of the shaft in situ to splint the periosteal tube. This procedure, however, really represents the method popularized by Winnett Orr and need not be discussed in this article.

Since there are many reports of repairs of defects in the tibial shaft by the use of the fibula, a portion of the opposite tibia or the femur, one must conclude that excision of the tibial shaft is frequently followed by lack of regeneration. The imposing list of such cases should be a warning against resection of the tibial shaft whenever it can be avoided. I did not consider resection of the tibial shaft justifiable in my cases unless conservative treatment had been well carried out and had failed, leaving the patient either profoundly toxic and overcome by his infection or with definite signs of advancing amyloid degeneration. It is certainly not a procedure to be undertaken lightly, but still it is prefer-

able in case the involucrum is allowed to remain. In the cases in which full regeneration of new tibial shafts has resulted, there was either no involucrum or very slight involucrum present at the time of operation, whereas two of the cases that have not to date been successful showed marked involucrum.

As will be seen by the table, the duration of the osteomyelitic process has had no influence on the subsequent regeneration of a new tibial shaft. All of my cases gave cultures of staphylococci, though the sub-divisional type is unobtainable. One case was reported as hemolytic *Staphylococcus aureus*.

The general health was very poor in all cases, with definite amyloidosis apparent in three of them clinically. In every instance it was a question whether any process would save the child's life. In all, the general health has returned to normal at this time, though in one there has been no influence on healing of the secondary foci of infection. It is interesting to note that among these six cases of tibial infection there were present twenty-one other foci of infection, probably all meta-

static in nature. It is of still greater interest to note that in only one case have these metastatic foci failed to heal promptly following the excision of the main focus, the tibial shaft. They have remained healed to the present time.

Operative procedures directed toward the osteomyelitis of the tibiae and secondary foci, previous to osteotomies, numbered more than thirty, better than an average of five operations to each case.

Subsequent operative procedures, necessitated by infection, have been three in number. They consisted of a sequestrectomy from the distal stump of the diaphysis in two cases and incision

for paronychia of the great toes in a third case. None of the three cases in which complete new weight-bearing tibial diaphyses were regenerated have required a secondary operation for infection or for the securing of continuity of the new tibial shaft. One of the patients fractured his new tibia twenty-three months after osteotomy and developed a fibrous nonunion requiring a sliding graft. At the time the sliding graft was implanted, new medullary bone structure was encountered within the regenerated tibial diaphysis.

Permanent shortening of the leg is a matter of extreme importance and has occurred to some extent in every case. Among the three cases of complete new tibial shafts, the loss in length amounts to one-fourth inch in one case, five-eighths inch in the second and 1 1/4 inches in the third. This shortening seems to occur immediately following operation and also through loss of growth due to injury of the epiphyseal plate by the infectious process. Two of the patients with complete regeneration suffered injury to both the proximal and the distal epiphyseal plates preoperatively, by the infectious process, and the third patient had an involvement of only the distal epiphyseal plate.

Fig. 2 (J S)—A four days after osteotomy showing the area of widely excised shaft with drainage tubes and plaster splint in place. B six months after operation with practically completely reformed tibial shaft. C, fourteen months after operation with completely reformed tibial shaft.

able to amputation of a limb or an eventual death or disability following amyloid disease.

Six case histories are summarized in the accompanying table in which a subperiosteal resection of the tibial shaft and involucrum was done. Three of these regenerated complete new diaphyses, and three to date have failed to do so completely. From a review of the literature and a tabulation of my own end-results, it would seem that the age of the patient was the most important factor in the process of regeneration. I would never expect to obtain a new weight-bearing unit in an individual past adolescence, and I believe that even at this period it is doubtful whether one can rely on sufficient regeneration. I would feel that before the age of 9 years in every case regeneration will take place if the whole periosteal tube is left intact.

I do not believe that leaving the involucrum is necessary to regeneration, and the accompanying roentgenograms show that such involucrum was not retained. Perhaps it would have been better to leave the involucrum in situ to speed up the process of regeneration and to increase the size of the newly regenerated shaft. There is always the danger of leaving sequestrums

New marrow cavities have regenerated through all three of the newly formed tibial diaphyses. Fractures of the new shaft occurred in one case only. In this case, which fractured twice, union was spontaneous in one instance and a sliding graft was necessary in the other. In one case an adherent scar required excision, and following excision the tibial shaft increased very rapidly in lateral diameter. In another instance, owing to the acute illness of the child, the periosteal tube was packed wide open. The result was a rapid formation of a new flat tibial shaft on the external surface of the leg. This required a plastic operation to the soft tissue and skin through a grossly infected area. There was a highly successful immediate outcome, but an unquestionable retardation of the growth of the new diaphysis. To date, a complete shaft has not formed.

When regeneration is going to occur, as seen in these cases, it occurs fairly rapidly. Within a month, a continuous new faint line of calcium is seen lying within the periosteal tube. From this point on the development of the new tibia proceeds in speed with direct relation to the youth of the child. One boy, aged

The operative technic is very simple. It consists of the resection of the tibial diaphysis subperiosteally, leaving pointed wedges attached to the proximal and distal epiphyseal lines. This should be done even if the wedges left are grossly infected, so as not to disturb the epiphyseal plates more than need be. In most instances removal of the grossly infected diaphysis will allow the patient's resistance to overcome all other infectious loci present, including the remaining diaphyseal stumps. If the removal of sequestrums from these stumps at a later date is necessary, it is a simple matter. The periosteal tube should be completely closed along the line of incision by sutures separate from those used to close the skin and subcutaneous tissues. This will prevent an adherent scar. Drainage, which is necessary, will take place at each end of the operative wound where the ends of the diaphysis have been left. The Orr method of postoperative care, which of course includes a plaster boot from groin to toes, is the most satisfactory.

The reports of cases would be so voluminous that they have been omitted. The essential facts have been included in the table.

CONCLUSIONS

1 Six cases are reported in which the tibial shafts were removed subperiosteally, including any involucrum, for osteomyelitis with extreme sepsis and multiple foci.

2 Complete regeneration of a new tibial diaphysis containing a new medullary cavity has been shown to have occurred in three instances.

3 The procedure is an extremely radical one, to be used only when the alternative is a conceivable amputation or death of the patient, from chronic sepsis.

4 Shortening may always be expected. After the age of 8 years failure of regeneration, in whole or in part, will probably necessitate later osteoplastic procedures.

5 All these results and conclusions must not be accepted as final, since obviously, completion of this study cannot be carried out for another ten years.

58 East Sixty-Fifth Street

Fig 3 (F W)—A old sclerotic deformed remnant of original tibial shaft. B fibula very lightly shown but absence of tibia definite. C five months after osteotomy showing grossly incomplete regeneration at that time.

6 years was walking without support on a completely regenerated tibia within nine months. A second child, aged 7 years, had a completely regenerated new tibia within a year, though weight bearing was not allowed until fifteen months after operation. A third boy aged 8 years had a new tibia, much smaller in size than in the preceding two cases, with weight bearing in sixteen months. The remaining three patients were 9, 11 and 16 years of age. Incomplete new shafts were reformed within about five months but in these cases the new bone formation subsequently proceeded no further. One of the latter (F W) was too recently operated on to determine the outcome.

From these patients whose ages were 6, 7, 8, 9, 11 and 16 years one must judge that to expect complete regeneration of a new tibial shaft beyond the age of 8 is to invite failure. I do not mean by this that one should never remove a tibial shaft beyond that age. Frequently one has no other choice except that of amputation or prolonged sepsis with its attendant untoward changes. Granting that a new tibial shaft is not developed as occasionally happens, the literature is full of instances in which the defect has been subsequently corrected by osteoplastic operations.

ABSTRACT OF DISCUSSION

DR D B PHENISTER Chicago I agree with what Dr Bosworth had to say about subperiosteal resection except with reference to the time and the extent to which it is carried out. The ideal treatment of osteomyelitis would be subperiosteal resection if regeneration of the shaft always followed. That would lessen the mortality, hasten the period of repair, and lessen the frequency with which the disease recurs. Unfortunately because of frequent failure of regeneration of the shaft, great restrictions have to be placed on the use of the procedure. I think it should be used in those locations in which it makes no difference whether regeneration of the shaft takes place or not. For instance, all osteomyelitis of the rib and osteomyelitis of the fibula should be treated by subperiosteal resection because it doesn't matter very much whether there is regeneration or not. It should also be used in a limited number of cases of severe infection when it looks as if the life of the patient is threatened. Regarding the time I don't think that it should be performed on the long bone except between the second and sixth weeks during which the soft involucrum can be left behind. That is, it should be performed after an involucrum has started out but before it is densely ossified. If one waits until it is densely ossified and then excises the shaft along with the involucrum one will get a failure of regeneration in such a high percentage of the case as to make the procedure unjustified.

DR J. E. M. THOMSON, Lincoln, Neb. Although this procedure may be indicated in certain instances it has a very limited place in the treatment of osteomyelitis and if it is used promiscuously, dire results will follow. I made an analysis of sixty-one cases of osteomyelitis of the tibia that have come to a private clinic (I am speaking of the work of Drs. Orr and Thomson in the clinic). In this series I found that only one osteotomy had been performed. There were five patients who came within the age limits in which according to Dr. Bosworth this operation would be appropriate. Two of these patients were 6 years of age, two were 7 and one was 8. Three were weak and had chronic sepsis. Two showed amyloidosis and emaciation. In one of these cases both tibias were involved. Four of these patients had previous operations. Involucrum was present in three and the complete shaft was involved in five. Four of the operations consisted of a complete opening of the length of the shaft and adequate drainage. In one there was wide opening of the lower third. Osteotomy was performed in one case. All these were treated by the Orr method of petrolatum pack and cast. As to the results, one patient was operated on again ten years later, her leg has taken place in four cases and in the one case in which the shaft was removed in November 1930 drainage continued for six months. With weight bearing complete shaft regeneration took place thirteen and one-half months after the operation. In considering these figures one should keep in mind the fact that one of these patients had osteomyelitis of both tibias. I believe from this study that thorough drainage and adequate after treatment obviate the necessity of doing an osteotomy. I had the same experience with osteotomy that Dr. Bosworth had in that the shaft was entirely loosened by the disease process.

DR DAVID M. BOSWORTH, New York. These cases were extremely bad ones. I would not remove a tibial shaft unless it was a matter of doing that or amputating the leg. I think that every one who has seen cases of failure of regeneration of the tibial shaft will agree in this.

EXPERIMENTS WITH ANESTHETICS

IV LESIONS PRODUCED IN THE SPINAL CORD OF DOGS BY A DOSE OF PROCAINE HYDROCHLORIDE SUFFICIENT TO CAUSE PERMANENT AND FATAL PARALYSIS

JOHN S. LUNDY, M.D.

HIRAM E. ESSEX, Ph.D.

Assistant Professor of Physiology, the Mayo Foundation for Medical Education and Research, University of Minnesota Graduate School

AND

JAMES W. KERNOHAN, M.D.

ROCHESTER, MINN.

We wished, in our study, to find the dose of anesthetic agent required when given subdurally to produce permanent paralysis of the hind legs and permanent changes in the spinal cord. Since procaine hydrochloride is the safest and most universally employed drug for spinal anesthesia, our experiments were confined to its use. The data here reported deal chiefly with results following subdural injection of huge doses of procaine in the dog. It was found necessary to give very large doses of procaine in definite concentration to produce permanent ill effects as judged by the behavior of the dog and the microscopic examination of the spinal cord.

Davis, Haven, Griggs and Emmett¹ have reported that a dose of procaine suitable for man when given

subdurally to a dog, has resulted in changes in the membranes of the spinal cord and in the spinal cord itself. These changes, however, were not permanent.

EXPERIMENTS

In preparation for injection the dogs were preanesthetized and were placed on the Deltant table, as modified by Essex and Lundy.² The injection which was made between the fourth and fifth lumbar vertebrae was carried out with technique that would ensure asepsis. Unless spinal fluid aspirated freely before and after the injection the experiment was considered unsuccessful and was discontinued. When indicated, artificial respiration was given by means of a pulmonary ventilator. With two or three exceptions dogs weighing between 18 and 30 Kg. were used. The entire spinal cord usually was removed after death. In selected cases when death did not occur spontaneously the dogs were killed from seven to ten days following the injection. Sections were made from the lumbar, thoracic and cervical regions of the spinal cords. Hematoxylin and eosin and Weigert's myelin sheath stains were used. In order that the pathologist might be unbiased in his examinations he was held in ignorance as to the previous treatment of the respective animals, the spinal cords of which he was to study. Control experiments were carried out; these will be described later.

Results.—Twenty dogs (table 1) were given intradural doses of procaine ranging from 500 to 2,500 mg. The concentration of the drug in the injected solution varied from 6.25 to 50 per cent. So far as permanent effects were concerned the concentration of the drug was found to be quite as important as the total dose. For example, 5 cc. of a 25 or 50 per cent solution of procaine (1,250 and 2,500 mg. respectively) invariably caused changes in the spinal cord associated with permanent paralysis of the hind legs. However, 25 cc. of a 50 per cent solution (1,250 mg.) or 10 cc. of a 12.5 per cent solution (1,250 mg.) failed to produce permanent paralysis or changes in the spinal cord. We were interested to determine the concentrations of solutions of procaine lower than 25 per cent that would cause comparable effects. Five cubic centimeters of a 20 per cent solution of procaine (1,000 mg.) produced permanent effects that differed only in degree from those caused by 5 cc. of a 25 per cent solution. With the former concentration and quantity degenerative changes extended only as far cephalad as the mid-thoracic region, whereas with the latter concentration and quantity lesions extended as far cephalad as the cervical region of the spinal cord. Five cubic centimeters of a 17.5 per cent solution of procaine (876 mg.) did not result in permanent paralysis. It is evident, therefore, that the minimal concentration of procaine that will produce permanent paralysis in doses of 5 cc. lies between 17.5 and 20 per cent.

In an effort to come to some conclusion as to the relative concentration of the anesthetic at different levels within the spinal canal and also as to the degree of permeability, trypan blue and methylene blue (methylthionine chloride U. S. P.) were added to the solution of the anesthetic. These dyes appeared to increase the toxicity of the solution since both animals used in this connection quickly succumbed.

In the two instances in which 5 cc. of a 50 per cent solution of procaine was given respiration was par-

lyzed for four and eight hours, respectively. In another experiment respiration was paralyzed for two hours and forty-four minutes following injection of 10 cc of a 12.5 per cent solution. This animal failed to exhibit any permanent effects. All three of these dogs were kept alive by artificial respiration³ throughout the period of respiratory paralysis at the end of which period respiration became spontaneous and adequate.

3 Lundy J S. Adequate and Properly Controlled Artificial Respiration for Surgical Patients by Means of a New Pulmonary Ventilator. Proc Staff Meet Mayo Clin 7: 225-228 (April 13) 1932.

Since the changes in the spinal cord were peripheral in position and such as might be expected to follow increased intradural pressure, a series of control experiments (table 2) designed to increase the intradural pressure were performed. In two instances sufficient physiologic solution of sodium chloride was given to produce very definite symptoms. The salient features were extension of the head and neck, with rolling of the eyes, loss of sphincteric control with voiding of feces and urine, and momentary cessation of respiration. These animals recovered almost immediately and

TABLE 1—Summary of Protocols

		Dose Mg	Mg per kg	Volume Cc	Per Cent			
1	18.5	2.00	132	50	50.0	Paralyzed for 4 hours	Permanently paralyzed	In the lumbar portion of the spinal cord there was a slight amount of hemorrhage in the peripheral portion (subpial zone) associated with superficial degeneration of the myelin sheaths. The thoracic portion of the spinal cord was similar to the lumbar except that there was less hemorrhage. Degeneration of the myelin sheaths was less marked in the upper thoracic region and was absent from the cervical cord.
2	96.5	2.00	94	50	50.0	Paralyzed in 7 minutes; remained so for 8 hours	Permanent paralysis; death in 3 days	
3	24.5	1.250	51	50	25.0	Paralyzed for 1 hour 24 minutes	Permanently paralyzed	In the lumbar portion of the spinal cord there was severe but superficial degeneration of the myelin beneath the pia mater with only one small hemorrhage. In the thoracic portion there was only one small patch of degeneration beneath the pia mater. The spinal cord above this level was normal.
4	22.0	1.500	56	50	25.0	Dog died (inadequate ventilation)		
5	25.0	1.250	44	50	25.0	Died suddenly		There was no change in the myelin at the lumbar portion of the spinal cord but there were a few small petechial hemorrhages below the pia mater in one lateral column. There were no changes above the lumbar level.
6	90.0	1.250	62	50	25.0	Paralyzed for 2 hours	Permanently paralyzed	
7	18.5	1.250*	77	50	25.0	Not adequate	Dog died of asphyxia	
8	25.5	1.000	51	50	20.0	Paralyzed for 2 hours	Dog died 3 days following injection	There was definite degeneration in the lumbar segments of the spinal cord as seen with the Weigert myelin sheath stain but the hematoxylin and eosin stains indicated even more extensive degeneration. This degeneration was most marked on one side above the lumbar region there was no degeneration of the myelin of the spinal cord.
9	90.5	5.00	42	50	17.5	Paralyzed for 15 minutes	No permanent effects	There were no changes in the spinal cord at any level with any stain. There was some diminution in the myelin of some of the nerve roots but this seemed to be due to excessive differentiation. There was no menin- gitis in this or any other specimen examined.
10	50.0	1.500	41	25	50.0	Adequate throughout	No permanent effects	
11	24.0	1.500	52	25	50.0	Adequate throughout	No permanent effects	
12	25.2	1.500	44	25	50.0	Adequate throughout	No permanent effects	
13	15.8	1.250	79	25	0.0	Adequate throughout	No permanent effects	
14	11.0	625	52	25	25.0	Adequate throughout	No permanent effects	The spinal cord was entirely normal throughout.
15	90.0	1.250	62	100	12	Adequate throughout	No permanent effects	
16	18.3	1.500	68	100	12.5	Paralyzed for 2 hours 40 minutes	No permanent effects	
17	25.5	625	26	100	6.5	Complete and permanently paralyzed	Dog died	There were slight degenerative changes in the peripheral portion of the spinal cord immediately beneath the pia but there were no hemorrhages. All other portions of the spinal cord and nerve roots were normal except such changes as may be accounted for by staining artefacts.
18	14.5	500	74	20	2.0	Adequate throughout	No permanent effects	
19	6.0	600	70	60	10.0	Adequate throughout	No permanent effects	The spinal cord was entirely normal.
20	25.0	0	52	0	1.0	Adequate throughout	No permanent effect	The lumbar portion of the spinal cord stained with Weigert myelin sheath stain was normal but in the section stained with hematoxylin and eosin there was a focal circumferential region of degeneration evidently the site of a needle puncture. All other portions of the spinal cord were normal.

* With 100% solution of proaine
* With 10% solution of proaine

ran about the laboratory in an apparently normal manner

The experiments just described indicated that pressure, per se, was not the explanation of the changes in the spinal cord, therefore the next control experiments were performed to determine whether the osmotic pres-

anesthetic agent, in terms of body weight, should always be accompanied by recommendations concerning the concentration in which the agent should be given

We are unable to offer any satisfactory explanation for the permanent effects of certain doses of procaine in certain concentrations. It has been shown that the permanent changes in the cord that result in permanent paralysis of the hind limbs of dogs given 5 cc of from 20 to 25 per cent solution of procaine are not due to intradural pressure or to the osmotic pressure of the solution. It might be argued that the long period of low blood pressure that invariably accompanies such spinal anesthesia might result in anemia of the spinal cord, but in certain instances permanent effects did not follow complete respiratory paralysis that endured nearly three hours during which time we have reason to believe the blood pressure remained at a level comparable to that of dogs permanently affected.

The central nervous system of the dog is capable of withstanding the action of huge doses of procaine. The doses used for man are proportionately much less. It is probable, therefore, that many of the accidents following the use of spinal anesthesia in man are due to factors other than the action of the anesthetic agent. This may not be true of some other local anesthetics, since Spielmeier,⁴ working with dogs and monkeys, obtained with stovaine (amylcaine hydrochloride, B P) in a maximal dose of 140 mg, lesions in the cord similar to those we obtained with procaine, except that in certain instances with minimal doses he obtained maximal effects. He stated that these degenerative

Fig 1—Cross section of the lumbar region of the spinal cord. The subpial zone on the right *a* shows marked destruction of the myelin sheaths; on the left *b* the myelin retains its normal staining qualities. Only the periphery shows the myelin degeneration; the center of the spinal cord is intact. The nerve roots on either side are normal. (Weigert myelin sheath stain)

sure of the fluid might be the significant factor. To that end a solution of dextrose isotonic with 25 per cent solution of procaine was used. This required a 40 per cent solution. Injection of 5 cc of this solution

TABLE 2—Control Protocols

Dog	Weight kg	Solution Injected	Comment
21	26.0	10 cc physio- logic sodium chloride	Animal not injured in any way
22	15.5	6 cc physio- logic sodium chloride	Animal in good condition soon after injection; no permanent effects
23	23.0	5 cc of 40 per cent dextrose	Animal gave signs of discomfort for 37 minutes; became quiet soon afterward and was in good condition within an hour; no permanent effects
24	20.2	5 cc of 40 per cent dextrose	Throughout period of observation which lasted 1 hour and 13 minutes animal in good condition
25	25.0	5 cc of 18.5 per cent urea	Animal in good condition the following day; urea caused slight anesthesia
26		No injection	Brain normal; medulla and cervical and upper thoracic portions of cord negative with Weigert's and hematoxylin and eosin stains

did not have a significant temporary effect and was without any permanent effect on the two dogs in which it was used.

A similar experiment was carried out with a solution of urea (18.5 per cent), which was made isotonic with 25 per cent solution of procaine. As might have been expected the urea produced slight anesthesia for a short period, but there were no permanent effects.

Comment—These experiments have shown rather conclusively that the concentration of procaine used in spinal anesthesia is quite as important as the total dose. Consequently, recommendations concerning the dose of

Fig 2—Normal dark staining myelin sheaths on the left. On the right almost complete destruction and loss of staining properties of the myelin. Numerous scavenger cells contain undigested or undegenerated fragments of myelin. In the intermediate zone are some swollen and disintegrated myelin sheaths. (Weigert myelin sheath stain, X 125)

changes in the cord are due to the contact effect of the drug on the myelin sheaths. This explanation is not

entirely satisfactory in the case of our experiments, but we have nothing better to offer

HISTOLOGIC CHANGES

There were definite changes in the spinal cords of dogs of which the hind limbs became permanently paralyzed. These changes were constant in that they affected the periphery of the spinal cord and did not penetrate deeply into its substance, but they varied slightly in the depth to which they penetrated and the distance to which they extended toward the medulla oblongata. There was destruction of the myelin sheaths in the zone beneath the pia mater, in the posterior, lateral and anterior columns of the spinal cord. The myelin sheaths were swollen, nodular and fragmented, associated with the formation of large vacuoles, giving these portions of the spinal cord a spongy appearance. The axis cylinders were also swollen, nodular and fragmented. The degree of destruction of the myelin sheaths and axis cylinders depended, in part, on the survival period of the animal after the injection. The degeneration of the myelin sheaths was limited almost exclusively to the subpial zone, there were no degenerative changes in the ganglion cells. The pia mater and the arachnoid were not thickened, and there was no inflammation in the subarachnoid space. There were no polymorphonuclear leukocytes or lymphocytes in the substance of the spinal cord, but there were many scavenger cells in the zone of degeneration of myelin sheaths. The nerve roots, anterior and posterior, which were present in the subarachnoid space did not have any destruction of the myelin sheaths or axis cylinders but appeared normal. Yet these were subjected to the same pressure as the periphery of the spinal cord and were also completely surrounded by the solution of procaine. All the blood vessels in the subarachnoid space and in the spinal cord appeared to be quite normal, and no thrombosis or occlusion was present. There is no satisfactory anatomic or physical explanation of the destruction of myelin sheaths in the periphery of the spinal cord which at the same time will explain the fact that the nerve roots in the subarachnoid space escape a similar fate.

INFERENCES

The results obtained clinically with the method of spinal anesthesia used at the Mayo Clinic and those obtained in these experiments are strikingly similar in one respect. Clinically, it is obvious that a dose of procaine will produce different degrees and duration of anesthesia, depending somewhat on its dilution as it is injected into the spinal fluid. For example 3 cc of 5 per cent solution (150 mg) gives more profound and longer anesthesia than 5 cc of 3 per cent solution (150 mg). Experimentally, it became obvious that the results were constant with respect to so many cubic centimeters of a certain concentration of solution of procaine injected into an animal. Every animal that became permanently paralyzed died from four to ten days after injection of the anesthetic intraspinally, whereas none of the animals died that were not permanently paralyzed. In order to keep the paralyzed animals alive long enough for the lesion to be visible it was necessary to catheterize them, to tube feed them with milk and syrup and to nurse them carefully for days. Five cubic centimeters of 20 per cent solution or of solution of greater concentration caused permanent paralysis. Five cubic centimeters of 17.5 per cent solution or of solution of lesser concentration did not cause permanent paralysis. Also a small quantity

2.5 cc of 50 per cent solution, even, did not produce permanent paralysis, and 10 cc of 12.5 per cent did not produce permanent paralysis.

We have had one clinical case, that of a small man who was to be operated on for bilateral inguinal hernia, and 2 cc of 10 per cent solution of procaine (200 mg) was injected between the third and fourth lumbar vertebrae. On the following day the patient had some difficulty in moving his legs, was unable to void the urine, had to be catheterized, and had some abdominal distention. On the next day these effects had disappeared and except for these symptoms, which existed for twenty-four hours, convalescence was uneventful.

Since this experience we have avoided the use of solutions stronger than 7 or 8 per cent and commonly employ concentrations of 3, 4 or 5 per cent solution as it leaves the syringe.

The results here reported deal with spinal cords which there is every reason to believe were normal. It is desirable to know the effect of procaine on abnormal spinal cords because, throughout the literature, abnormality of the central nervous system is given as a contraindication to spinal anesthesia. A question has been raised as to the possibility of injury from the ordinary dose of procaine and also apothecaries to a spinal cord in which there is already pathologic change. Judging from our experiments, it seems probable that when paralysis follows the use of ordinary doses of a spinal anesthetic agent, the spinal cord was previously diseased. If this hypothesis is correct, it would be difficult to determine, in a given case, that the spinal anesthetic had done more than precipitate the clinical symptoms that would have come on gradually at a later period, even if the spinal anesthetic had not been given.

ABSTRACT OF DISCUSSION

DR HALE HAVEN, Chicago. My associates and I used in our animals concentrations of the agent comparable to those used in man. With the Marchi method from twenty to thirty days after injection we were able to see myelin changes somewhat similar to those described by the authors. In our experience these changes were likewise present in the nerve roots. In all cases at this time we were able to note passive changes in the ganglion cells of the gray matter similar to those seen in retrograde or so called Wallerian degeneration. We did not feel these degenerative changes were permanent, because they were absent or evident only to a slight degree in animals kept alive ninety days. In *in vitro* experiments with concentrations of procaine as low as 0.5 per cent in physiologic solution of sodium chloride the spinal cord showed peripheral neurolysis similar to that demonstrated by Weil, saponin and other neurotoxins being used and quite similar in their Weigert picture to the slides shown here. The most constant change observed and one which appeared permanent was a sterile inflammatory reaction of the meninges which in the older animals reached a state of fibrotic scarring. The change was so constant and so seemingly more pronounced in those receiving larger doses that I am at a loss in explaining the difference between the authors' results and ours. I should like to ask if they have any explanation if they observed their animals as long as three months and if the changes were still present. I should also like to know if they made any investigation of the condition of the ganglion cells of the gray matter with specific stains for Nissl granules. Because of the milder and more passive changes that we observed in the nerve roots in the ganglion cells it was our feeling that it had a myelolytic effect and that it was due to this myelolytic effect. I have come to a regard to

DR. JAMES W. KERNOLIAN, Rochester, Minn. There seems to be some diversity of opinion about the effects of procaine on the central nervous system. It must be remembered that the anatomy of the dog is different from that of man. In the dog, the dura mater and the arachnoid completely and closely surround the spinal cord, just as a rubber glove surrounds the finger and in that respect are quite different from the pia and dura mater around the spinal cord of human beings. Consequently, pressure alone may be of importance. It was on that basis that Dr. Essex used other solutions such as dextrose and urea, but found again that alone they had no effect on the cord. I would like to draw attention to the appearance of the spinal cord in which degeneration was limited to the periphery. The nerve roots, lying free in the subarachnoid space and completely surrounded by the procaine, were not affected by it. This was constant throughout the series, and there were no changes in the cells of the anterior horn. I feel that the procaine does not have any demonstrable or permanent effect directly on the normal myelin. These dogs died from about eight to twenty days after the anesthesia had been given and there was no inflammatory reaction, either in the nerve roots here or in the subarachnoid space. There was some reaction in the spinal cord, but this was the result and not the cause of the degeneration. Scavenger cells were present in large numbers. What would have happened at the end of three months I cannot say.

DR. HIRSH E. ESSEX, Rochester, Minn. We are in accord with Dr. Haven. We think these lesions are due to the toxic action of the drug on the cord. We have ruled out the probability of their being due to a pressure phenomenon or to an osmotic action of the drug.

STRICTURE OF THE RECTUM

SOME OF ITS PROBLEMS

COLLIER F. MARTIN, M.D.
PHILADELPHIA

The study of stricture of the rectum is as fascinating as the treatment is discouraging. The etiology for the most part is unverified, the literature is confusing, and the compilation of statistics by various authors is not standardized. I had intended to classify stricture as to the apparent pathologic conditions such as syphilis, gonorrhea, tuberculosis or those following simple pyogenic infection. In looking over my statistics I found this to be absolutely impossible and was forced to look for some reason for this condition.

In my study I was confronted with the following questions:

1. Why should the occurrence be most usual between the ages of 20 and 40?
2. Why is the Negro race peculiarly susceptible?
3. What is the relationship of stricture to venereal diseases, namely, syphilis and gonorrhea, and to tuberculosis?
4. What importance can be attached to a history of pelvic inflammation or pelvic operation in the female?
5. Why does it occur most frequently in the female?

In a series of 227 cases tabulated by Dr. Harry E. Bacon from the records of the Graduate Hospital of the University of Pennsylvania, and the Philadelphia General Hospital, I note that only ten cases occurred before the age of 20, while 204 were noted between 21 and 50 (90 per cent). There was a marked decrease between 41 and 50, but after 50 there were only thirteen cases noted. Of the first ten cases, seven were known to be congenital, probably the other three may be included under this classification. After 50 years

of age there is a sudden drop from thirty-seven in the previous decade to six, four and three in the three succeeding ten year periods. I can interpret this to mean only that stricture appears most frequently during the period of marked sexual activity. The age incidence of the patients corresponds very closely with tables published by Rosser,¹ Buie² and Hayes.³

The marked reduction in number in the last years of life may be due to the fact that these patients rarely survive after the age of 50.

It is rather curious to note that 167 of our cases, or 81.6 per cent, occurred in the Negro race, and all these were females. There are still twenty-one cases in which the color was not mentioned, so that the percentage may be even greater. Rosser seems to think that the prevalence of stricture in the Negro race may be accounted for partly by the racial predisposition to develop massive inflammatory deposits, which tendency he named "fibroplastic diathesis." For many years the term 'negromata' has been used by us as best describing these peculiar tissue masses. Rosser also believes that the Negro is particularly susceptible to venereal infection, as the result of the social conditions under which he lives. It is unfortunate that there is no close check up in the tables as to how many of the females were Negro or white. Our own tables are incomplete in the same detail.

As far back as 1811, Copeland⁴ stated that there seemed to be some relationship between the formation of rectal stricture and venereal diseases and that the subject should be investigated. Since that time various authors have tried to classify stricture as being due to syphilis, gonorrhea or tuberculosis. It would seem to me that this classification is not practical, as frequently I see two or more of these diseases present in the same patient. It is much like accusing the patient of eating horsemeat because a saddle was found under the bed.

The foregoing summary convinced me that something was wrong with my point of view. Since February, we have tried to make a detailed study of fifteen cases of rectal strictures under treatment in the Graduate Hospital, and ten others made available through the courtesy of other institutions. All of the patients were Negro females, the youngest was 22 and the oldest 48. No stricture has been noted in the male in our service for two years, provided congenital stenosis and a few postoperative contractions at or near the anorectal line are excluded. These patients all had massive perirectal deposits of inflammatory tissue, with marked contraction of the lumen of the bowel and multiple rectal and perirectal infections, with fistulas involving the perianal area. Rectovaginal fistula was frequently noted, and two cases showed marked involvement of the vulva. Many of these patients gave a history of previous pelvic infection and pelvic operations, the exact character of which could not be ascertained. The more I studied these cases, the more I became convinced that there must be some specific cause for the peculiar pathologic condition encountered in the Negro race. It was suggested to me as a possibility that an infection which produced a condition named 'lymphogranuloma inguinale' (climatic bubo) might play a part in this picture. In 1913, Durand, Nicolas and Favre of Lyons demonstrated that climatic

¹ Rosser, Curtice. Rectal Pathology in the Negro. J. A. M. A. 84: 93 (Jan. 10) 1925. Clinical Variations in Negro Pathology. *ibid.* 87: 2084 (Dec. 18) 1926.
² Buie, L. A. Benign Strictures of the Rectum. J. A. M. A. 81: 1357 (Oct. 20) 1923.

⁴ Copeland, Thomas. Diseases of the Rectum and Anus. Philadelphia 1811.

bubo and lymphogranuloma inguinale were a single entity. Wolf and Sulzberger suggested the term "lymphopathia venereum" as a substitute in terminology to avoid confusing the condition with the granuloma inguinale, in which disease Donovan bodies are seen in sections of the tissue. In looking up the literature in the quarterly index, one is struck by the many titles of papers under the heading "lymphogranuloma." It is no wonder that the condition has been overlooked by us as proctologists, since the titles of practically all the papers seem to refer entirely to urology or dermatology.

Apparently this disease was noted first in the male Negro, as the term climatic bubo would indicate. It has been described as a small initial lesion on the penis which appears from six to thirty days after intercourse. The primary lesion is small, painless and frequently unnoticed by the patient. It is nonindurated and non-suppurating, with sharply defined edges. The inguinal glands are involved early, usually in from one to two weeks following the initial lesion. They become swollen and slightly tender. The overlying skin becomes reddened and later violaceous. The glands mass together, with hard areas interspersed with softening. The disease is chronic and after months and years heals with dense scar formation and retraction of tissue.

Sulzberger and Wise⁵ say that rectal lesions are the inevitable sequel. Remembering that the lesions described occur in the male, I doubt this sequence of events and feel that it would be hard to show anatomically how stricture of the rectum would follow infection of the penis and inguinal glands. When the picture is carried further and it is seen that the female is infected through sexual relationship, and that this infection enters the cervix and posterior vaginal wall, it may be believed that perirectal and extra-uterine infection of the lymph channels and vascular systems may take place.

While no specific cause of infection has been discovered, it is believed that the infection is probably due to a filtrable virus. In 1925, William Frei suggested a clinical test of this disease, procuring an antigen from pus removed from the broken down inguinal glands. This is a dermal test and is quite simple to apply. In testing my cases I had to rely on outside sources for specific antigens. My first supply was obtained through the kindness of Dr. Descum McKenney of Buffalo. Later, a generous quantity was received from Dr. H. F. DeWolf of Cleveland. A control antigen was made of macerated inguinal glands removed from presumably healthy patients who had been operated on for hernia.

A positive Frei reaction was obtained in twenty of the twenty-five cases certainly a far greater number of patients than we found to have syphilis, gonorrhea or tuberculosis. It is just possible that this is a type of infection peculiar to the Negro race, just as granuloma inguinale is rarely found in white persons. Parenthetically, it might be a subject for study whether or not lymphopathia venereum and granuloma inguinale are not the same disease or at least clearly related. A history of previous pelvic operations, instead of indicating that the stricture followed the operation, might indicate that the patients were operated on because they had distinct symptoms referred to the pelvis and adnexa.

For the relief of these great sufferers we have tried many expedients such as proctotomy with or without

dilation, external proctotomy, after the method of Jelks, carbon dioxide snow, and colostomy. Many of the patients have been benefited but none cured. It is my firm belief that for the prolongation of life most of these patients must sooner or later have a permanent colostomy performed. To my mind, this would be the operation of election. Systematic treatment, with local drainage of the collections of pus, are indicated at all times. We have not decided on any medication. Apparently there isn't anything known now.

It would be impossible to go into detail as to the symptoms, clinical course and treatment of these cases in the space allotted, but I feel that our few cases materially change the statistics of inflammatory rectal stricture. The following views are believed by me to be essentially correct. Much investigation is necessary before they can be verified. This will take considerable time, but I feel that this may be considered a preliminary report. These views may be tabulated as follows, any single one of which might make a subject for extensive research.

1 Inflammatory stricture of the rectum primarily is due to a specific infection, classified variously as lymphogranuloma inguinale, climatic bubo or, more appropriately, lymphopathia venereum.

2 It is a disease peculiar to the Negro, possibly because of some racial susceptibility.

3 In the female, the disease is expressed as a stricture, in the male the prominent features are a primary sore on the penis followed by an adenitis, which frequently suppurates.

4 Acute inflammatory symptoms are absent, except periodically, patients complaining little of acute pain.

5 The disease is slowly progressive, extending over periods of months or years, resulting in rather massive destruction of normal tissue.

6 To date, the disease may best be described as incurable and tends toward an inevitable fatal termination.

7 The condition is probably more widespread than one realizes and probably is very infectious, particularly to the Negro race.

8 In view of the seriousness of the complications following these infections, it certainly would seem that all cases should be reportable to attempt to lessen the spread of the condition.

9 Lymphopathia venereum, whether expressed as an adenitis in the male or as a rectal stricture in the female, well deserves the name given it of the fourth venereal disease and might well be placed near the top of the list in importance.

1831 Chestnut Street

ABSTRACT OF DISCUSSION

DR. CLYDE W. MORTER, Milwaukee: All must agree with Dr. Martin's opening statement. The study of stricture of the rectum is as fascinating as the treatment is discouraging. Is any one prepared to say that tuberculosis is the causative agent in stricture or that it has any connection with it except as a secondary infective factor? Reverse the hypothesis and assume that tuberculosis is the exciting factor—what then becomes of the part played by secondary infection? All have seen patients with acute gonorrhea of the rectum recover without stricture. Can it be said then that a stricture due solely to gonorrhea ever occurs? My belief is that stricture is the culmination of a series of unfortunate events that finally result in extensive narrowing of the lumen of the bowel and that the bowel itself is surrounded by a dense, chronically active inflammatory mass. The chronic process is the result of a low grade mixed infection which enters the rectum through the

⁵ Sulzberger, M. B. and Wise, Fred. Lymphopathia Venereum. A. M. A. 99: 1407 (Oct. 22) 1915.

effort at drainage. Dilatation by any method is unsuccessful as long as infection is present and is even capable of lighting up an infection in a dormant area. It is fully agreed that in the majority of intractable strictures a colostomy is not only advisable but a necessary procedure. Dr. Martin gives some interesting data in his series of cases with granuloma inguinale antigen reactions. Milwaukee has a relatively small Negro population. The records of Milwaukee County Hospital and Milwaukee County Hospital Dispensary brought out the interesting fact that only three cases of granuloma inguinale have been noted during the past six years. All have responded to treatment with antimony and potassium tartrate. I should like to ask Dr. Martin, if the idea that there is a specific test for granuloma inguinale is accepted, whether he thinks that by this means it will be possible to recognize lymphogranuloma early enough to institute treatment that will materially control its complications and duration. I should like to call attention to the recent report of Dr. Williamson and his collaborators in *THE JOURNAL* May 27, regarding the use of a newly recognized preparation, Fuadin."

DR. HERBERT T. HAYES, Houston, Texas. The predisposition to scar formation in the Negro was brought out by Dr. Rosser several years ago and he partially attributed the prevalence of stricture to this. I too hold this view. In all probability the few white people who develop strictures also have this scar-forming tendency. The various forms of ulceration that occur in the rectum from bacterial invasion begin its formation. Dr. Martin states that these cases are more frequent between the ages of 20 and 40, that is, during the most active sexual life. Strictures are more frequent in the female than in the male and are much more frequent in the colored female than the white. I believe that gonorrhea is the infection most often responsible. I have observed the formation of a stricture in cases of gonorrheal proctitis, in spite of all forms of treatment. The low percentage in the male is accounted for by the rarity of infections in the rectum. The Negro male has a higher percentage of urethral strictures and he has a gonorrheal urethritis more frequently. There are strictures resulting from various other infections. In regard to lymphogranuloma inguinale, the reports have been confusing. I do not believe enough data have been presented to ascertain whether it is a causative factor in rectal stricture. Some men are reporting a high percentage of positive Frei tests and others are not, however there is a high percentage of positive Wassermann tests in stricture, but that does not prove them to be syphilitic. The cases that I thought were definitely lymphogranuloma inguinale presented the characteristic swollen inguinal glands, discharging sinuses and elephantiasis of the vulva, anus and rectum. However, this is a new field of research and I hope that open-minded investigation will be fruitful of results. I agree with Dr. Martin that all forms of treatment, such as dilations, proctotomies, carbon dioxide snow and plastic operations, have proved to be only palliative measures and that these patients ultimately have to have a permanent colostomy.

DR. A. A. GOLDSMITH, Chicago. I should like to bring up the question of the possibility of dilatation of the strictures. I have had rather a small series compared to Dr. Martin. I have had two or three I could dilate rather efficiently. One was in a white man in whom it came on one year after an acute gonorrhea, at the time he was taking treatment for posterior urethritis. I have been able to keep the rectum open satisfactorily for several years. I see the patient once every two or three months and he has had no further trouble except some irritation. Another patient was a colored woman with marked stricture formation and it was possible to dilate her rectum. I agree that most of them cannot be dilated because of the tortuous channel about four inches long, which has many angles. In those two cases it was possible to dilate the stricture satisfactorily and I feel that these patients are better off now than they would be with a permanent colostomy.

DR. M. H. STREICHER, Chicago. At the University of Illinois we have had occasion through the cooperation of the dermatology department to obtain approximately nineteen cases of this type. In the group there were two white females and only one white male. There can be no question that not all the cases are venereal, gonorrheal or syphilitic. At the Cook County Hospital through the courtesy of Dr. Jaffe, I have had

the opportunity to study two postmortem cases, the only two on record in Chicago at present. They have been reported by the dermatologists before this time. A distinction is made pathologically from tuberculosis, namely, that in tuberculosis there is caseation while in lymphogranuloma inguinale there is suppuration. In all the cases that we have had, the Frei test has been positive. The cases, of course, were seen in the terminal stage.

DR. E. JAY CLEMONS, Los Angeles. I have maintained for fifteen years that rectal stricture is not a surgical disease. I have at present the carbon dioxide rectal stricture clinic of the Los Angeles County General Hospital. I handle certain of my problems as follows: Into the discharging sinuses I instill pure phenol (carbolic acid). The result is that most of these discharging sinuses close. Into the bowel I insufflate once in a week 4 liters of carbon dioxide gas under pressure of one tenth pound to the square inch. Because carbon dioxide is the most potent agent in combating saprogenic infection, the purulent sanguineous discharge from the rectum ceases. Carbon dioxide is absorbed from the rectum by the venous circulation and is carried to the lungs, producing there hyperventilation due to the excessive diffusion of gases. At the same time the excessive carbon dioxide in the body produces neutrality of the body fluids. In this way acidosis is lowered, the arthritis disappears, and the general health of the patient markedly improves. After the patient's general health has improved, the discharging sinuses have closed and the discharge from the rectum has become quiescent, I abstract enough heat with solid carbon dioxide to produce a profound edema of each cell of the remaining uncomplicated stricture. The consequence is that the hard, fibrous tissue changes to a soft, elastic state, and as the result the stricture opens.

DR. JOHN L. JELKS, Memphis, Tenn. In the South the cases are chiefly among Negroes. I have seen one white woman with this condition. Strictures of the anus should be classified properly first in contradistinction to those of the rectum, secondly, they should be classified scientifically on an etiologic and pathologic basis. There are amebic strictures, tuberculous strictures and strictures due to streptococcal infections and other conditions, but this is an entity. It is apparently a local and not a systemic condition. I want to suggest to those who are making special studies to examine their cases in every way before they begin treatment, for treatment may destroy the opportunity to learn much about the condition *per se*. In addition to antimony and potassium tartrate they might try a 20 per cent solution of copper sulphate and push it into the tissues with the electrical apparatus. Operation is not of any avail in these cases. Dilatation cannot be done. Colostomy is indicated first to get rid of the foul secretions, which occur in women in the proportion of about 95 per cent.

DR. COLLIER F. MARTIN, Philadelphia. I cannot answer these questions accurately, as my contacts with the cases have been too brief. Certain points have been stressed, principally the relationship to race and sex. All of the twenty-five cases reported were in women and all but one were colored. Ten out of the twenty-five gave a positive Wassermann reaction, twenty-one gave a history of a previous pelvic operation or a gynecologic history. A Frei test was recorded as negative in only two cases. One of these patients was colored and the other was a white patient in whom a lymphopatia was not suspected. The percentage of positive cases certainly is surprisingly large. I feel that Dr. Morter has the granuloma inguinale in mind and not the lymphogranuloma inguinale or lymphopatia venereum. Antimony and potassium tartrate is certainly fairly efficient in treatment of the former disease, but Dr. Descum McKenney tells me that he has had some encouraging results in the treatment of lymphopatia venereum. The new drug Fuadin, which may be given hypodermically and not intravenously as is antimony and potassium tartrate, seems to offer some advantages. This will be tried if a supply can be made available. The Graduate School of the University of Pennsylvania being located in an area populated principally by Negroes, offers a fertile field to obtain cases for study. Unfortunately it is rather hard to obtain a consecutive history from a member of this race and the recorded figures may present some inaccuracy. This work will be continued and further reports will be forthcoming.

PRODUCTION OF ESTRUS

RELATIONSHIP BETWEEN ACTIVE PRINCIPLES OF
THE PLACENTA AND PREGNANCY BLOOD
AND URINE AND THOSE OF THE
ANTERIOR PITUITARY

J B COLLIP, PH D, MD, HANS SELYE, MD
EVELYN M ANDERSON, MD
AND
D L THOMSON, PH D
MONTREAL

There are three distinct substances in the human placenta that are capable of producing estrus precociously when administered to immature rats or mice, the first is ether soluble, the second ether insoluble but alcohol soluble, the third alcohol insoluble. From the ether-soluble fraction Browne,¹ in our laboratory isolated an active principle in crystalline form, it proved to be identical with trihydroxy-estrin or theelol, whose most characteristic physiologic property is that, while highly active in immature intact rodents, it is relatively less active in adult or immature ovariectomized animals, possibly, as we have suggested, because in the presence of ovarian tissue it undergoes conversion into some more active modification such as ketohydroxy-estrin (theelin). The active principle of the second fraction has been termed emmenin in a previous report,² it displays the same characteristic property, and we believe it to be a compound of trihydroxy-estrin with some unknown substance that alters the solubility without greatly modifying the physiologic properties, it certainly requires the presence of ovarian tissue in order to display its full estrogenic activity, but it does not appear to stimulate the ovary and it has no marked action in male animals. The alcohol-insoluble fraction, however does stimulate the ovaries, causing the precocious formation of ripe follicles and corpora lutea when injected into immature female rodents and hence secondarily giving rise to the phenomena of estrus. It is with this fraction that the present discussion is chiefly concerned.

There is no reason to doubt that this ovary-stimulating substance is identical with the ovary-stimulating substances which circulate in the blood and are copiously excreted in the urine during pregnancy in the human female and which are the basis of the Aschheim-Zondek and Friedman tests for pregnancy and their modifications. In fact, we have latterly used preparations from pregnancy urine in preference to placental preparations, and we firmly believe that the results are completely interchangeable. On the other hand, from the time of our first publications³ on this subject, we have always maintained that this substance is not identical with the ovary-stimulating substance present in the anterior lobe

of the pituitary itself, and we have referred to the substance obtained from placenta or pregnancy urine as the "anterior pituitary-like hormone," a description which has commended itself to several other workers in this field. At first our reasons for drawing this distinction were slight differences in the physiologic response of normal animals to these substances, and the fact that the methods which extracted this substance from the placenta yielded only inactive preparations when applied to the pituitary itself. Recently, however, we have been able to devise and complete crucial and convincing experiments to prove the point, by investigating the behavior of the anterior pituitary-like hormone in hypophysectomized animals.

Smith⁴ was the pioneer in the study of the consequences of hypophysectomy in the rat, he showed, among many other important results which we have been able to confirm and extend, that the ripening of follicles in the ovaries ceased promptly and completely the ovaries atrophied, and the animals became permanently anestrus. Almost normal structure and activity could be restored to the ovaries, however, by implanting fresh hypophyseal material intramuscularly, and we have found that this result can also be attained by the administration of suitable extracts. On the other hand, reports in the literature on the effect of treating hypo-

physectomized animals with the anterior pituitary-like hormone (or "prolan" or similar preparations) are conflicting, partly because the number of animals available for experimentation has always been small. One of us (H S) has been able, by a modification of Smith's operative procedure, to prepare a large number of hypophysectomized rats wherewith to study the question. Rats hypophysectomized before puberty are found to react to treatment with the anterior pituitary-like hormone, not as normal rats do with enlargement of the ovaries, ripening of follicles production of corpora lutea and secretion of estrin, but by a somewhat inconspicuous and unexpected histologic change in the ovaries: the cells of the theca become transformed into luteal cells while the granulosa cells are unaffected.

This discovery had previously been made by Noguchi,⁵ and it suffices to dispose of the claims both of those who hold that anterior pituitary-like hormone behaves in the hypophysectomized rat as in the normal rat and hence might well be identical with the hypophyseal hormone itself and of those who hold that the anterior pituitary-like hormone has no action in the hypophysectomized rat and hence may be regarded as a pituitary-stimulating rather than an ovary-stimulating substance. It thus appears that the usual action of the

anterior pituitary-like hormone on the ovaries of the normal prepubertal rat or mouse (the Aschheim-Zondek reaction) is possible only because the hypophysis of the test animal is intact, and presumably because there circulates in the blood of the test animal a substance, originating in the pituitary, that is complementary to the anterior pituitary-like hormone and enables it to exert its full action on the ovary instead of merely producing thecal luteinization. In full confirmation of this view, it has been possible to show that small quantities of hypophyseal extracts, themselves possessed only of slight ovary-stimulating activity, are capable of acting in concert with the anterior pituitary-like hormone to produce ripe follicles and fresh corpora lutea, in short, the typical Aschheim-Zondek picture in the ovaries of hypophysectomized rats.

It is well known that when the anterior pituitary-like hormone and certain pituitary extracts are administered together to normal immature rats, the effect on the weight of the ovaries is much greater than when either is given alone, there is, in fact, a definite synergistic or complementary effect. Evans⁶ who first drew attention to this phenomenon, believed that it was the pituitary growth hormone which was concerned therein, but we have found decisive evidence against this theory, as Evans⁷ has also done. Nor is synergism with the anterior pituitary-like hormone displayed only by pituitary extracts of high gonad-stimulating potency, in fact, the substance responsible has not at present been identified with any of the known pituitary hormones. The very interesting question arises whether this substance, which enhances the action of the anterior pituitary-like hormone in the normal rat, is the same as the complementary substance required for the anterior pituitary-like hormone to exert its full effect in the hypophysectomized rat. At present this question cannot be decided, an affirmative answer appears to be

reasonable a priori, and it may be said at least that the two types of activity are closely associated in their distribution in various types of pituitary extracts. The accompanying tables indicate the magnitude of the complementary effect of a pituitary fraction labeled C, on the action of the anterior pituitary-like hormone in the normal rat. This C fraction is devoid of growth-promoting power, it is, however, by no means pure even in a physiologic sense. The question is of more than

academic interest, the anterior pituitary-like hormone has proved its therapeutic value, especially in the treatment of certain types of uterine hemorrhage,⁸ and it seems entirely possible that its scope could be considerably extended by giving in combination with it sufficient amounts of a purified pituitary extract to exert a complementary effect in the sense discussed. This would, at least, be more economical than relying on the expensive pituitary material to provide the whole of the physiologic activity required.

It is by no means easy to correlate these discoveries with demonstrations, such as that recently offered by Hisaw,⁹ that the gonad-stimulating activity of the pituitary extracts themselves can be split into two fractions, one causing purely follicular development and the other acting in conjunction with the first to produce luteinization. Since these experiments are not carried out on hypophysectomized animals, they cannot be compared directly with our own, and at present no plausible unifying hypothesis presents itself. With regard to the alleged multiplicity of the anterior pituitary-like hormone, the situation is possibly clearer. As is well known, Zondek¹⁰ believes that the ovary-stimulating effect of pregnancy urine preparations is due to the combined action of a follicle-stimulating "prolan A" and a luteinizing "prolan B." None of the many workers, including ourselves, who have carried out far-reaching purification of this material, have seen any sign of separation of these effects, and indeed the only evidence for Zondek's theory is the existence in certain urines, not collected during pregnancy, of an ovary-stimulating substance which has a predominantly follicle-stimulating effect and which Zondek regards as "prolan A." Believing as we do that the anterior pituitary-like hormone of pregnancy urine is derived from the placenta and is not necessarily identical with any truly hypophyseal principle, we are forced to suppose that when substances of this nature appear in the urine in the absence of tissue of placental type they must have a different origin (presumably hypophyseal) and may possess different physiologic properties. The testing of

the so called prolan A on the hypophysectomized rat may decide this question

A feature that soon becomes prominent in research in this field is the existence of quantitative species differences, Loeb¹¹ and Aron¹² in particular have done much service in revealing and emphasizing this fact. We¹³ were able to confirm their finding that the anterior pituitary-like hormone administered to young female guinea-pigs does not produce a typical Aschheim-Zondek effect but leads to thecal luteinization similar to that seen in hypophysectomized rats. Since it had been found that very young suckling rats also responded in this modified way to injections of the anterior pituitary-like hormone, a fact which we confidently interpret as due to the failure of the pituitary at this very early stage to supply sufficient complementary substance, we at first considered that the guinea-pig pituitary also failed to supply this substance in adequate amounts. But it may well be that the ovary of the guinea-pig is adjusted to a different balance of the two active principles and requires relatively a much larger amount of complementary substance than the rat ovary. This might explain Loeb's finding that implants of hypophyseal tissue from various species differ in their effect on the guinea-pig ovary. By far the nearest approach to an Aschheim-Zondek reaction is obtained when the donor species is also the guinea-pig, we may suppose then that the guinea-pig's pituitary contains abnormally large amounts, relatively at least, of the complementary substance and is adjusted to the particular needs of the guinea-pig's ovary. Thus again is of possible medical significance, since the work of Engle¹⁴ indicates that the primate ovary is in this respect more comparable to that of the guinea-pig than that of the rat. The situation may be compared to that which prevails with respect to the thyrotropic hormone, this is present in small amounts in the pituitary of the guinea-pig, which is very susceptible to the action of the substance, but is abundant in the pituitary of the relatively refractory rat.

It is tempting to suppose that the gonad-stimulating pituitary extracts contain as one active principle a substance physiologically similar to the anterior pituitary-like hormone, though probably not chemically identical with it, accompanied by one or more adjuvant or complementary substances. One might even facetiously refer to the "placenta-like" component of such pituitary

extracts, but it must be observed that this is by no means the only hypothesis for discussion and that, as we have already indicated, our present knowledge of gonad-stimulating pituitary extracts does not lend itself to treatment along these lines.

The experiments on which this paper is based have for the most part received preliminary publication¹⁵ and will shortly be described more fully elsewhere¹⁶. Our experience with hypophysectomized rats in this investigation encouraged us to use them as test animals

for the biologic assay of fractions obtained in a chemical dissection of anterior pituitary extracts. In this way we¹⁷ obtained a preparation that restored growth in hypophysectomized rats and yet was free from effects on the thyroid gland or the gonads, even when tested in the highly sensitive immature dove¹⁸. From extracts from which the growth hormone had thus been removed we¹⁹ prepared a fraction that stimulates the thyroid gland, as judged by histologic studies in normal guinea-pigs and normal and hypophysectomized rats, or, more advantageously, by its effect in raising the basal metabolic rate of hypophysectomized rats, these preparations, however, are not wholly devoid of effect on the gonads and suprarenals. More recently, we²⁰ have been able to obtain a fraction containing the adrenotropic hormone but practically without effect on growth, thyroid or gonads, it permits increase of size and restoration of the normal histologic picture of the suprarenal cortex in hypophysectomized rats. We²¹

have also shown that lactation, unlike pregnancy cannot continue in the absence of the hypophysis and have recently been able to confirm this finding in experiments with hypophysectomized mice

SUMMARY

The anterior pituitary-like gonad-stimulating substance of the human placenta and of human pregnancy blood and urine causes merely thecal lutemization when administered to hypophysectomized immature rats to very young suckling rats or to guinea-pigs. Hence when in the normal rat it produces enlargement of follicles and formation of corpora lutea, it does so by virtue of the presence of a complementary substance produced by the pituitary of the test animal. The presence of this complementary substance in pituitary extracts has been demonstrated, it is suggested that it may be identical with the substance which enhances the action of the anterior pituitary-like hormone on the ovaries of normal rats.

ABSTRACT OF DISCUSSION

DR J. P. PRATT, Detroit: The presentation by Dr Collip and his co-workers emphasizes the difficulty that clinicians experience in applying the fruits of the laboratory to the solution of clinical problems. The experiments on hypophysectomized rats can hardly be duplicated in man. Therefore the results they have obtained are applicable to human problems only through the dangerous and inaccurate process of reasoning by analogy. When the anterior pituitary-like substance is injected in rats and mice corpora lutea are produced in the ovaries, but when injected in women no such reaction occurs. What response is elicited in the latter case is a subject of considerable interest. In approximately 100 human specimens examined after injection of the anterior pituitary-like substance I have seen only one that suggested corpora lutea stimulation. The observations do not show anatomic variations corresponding to the time in the menstrual cycle at which the injection was made, nor do they differ in proportion to the amount injected. Sometimes no reaction occurs in the ovary. If any change is characteristic, it is an increase in atretic follicles. Although only slight anatomic evidence of reaction to the anterior pituitary-like substance can be demonstrated in the human ovary, it is not without physiologic effect, for certain types of metrorrhagia are benefited or corrected by administration of the substance. In some instances the favorable response is obtained in a very short time after the injection. Perhaps the authors will explain the manner in which the reaction takes place.

DR HARRY BECKMAN, Milwaukee: I find the whole subject so confusing that to hear a paper is of very little assistance to me. I am grateful to the authors for the excellent slides, which from the teaching standpoint are very valuable.

DR J. B. COLLIP, Montreal: I thank Dr Pratt for his discussion of the paper. The answer to the question he raised as to the mechanism by which the anterior pituitary-like hormone has given excellent clinical results in certain cases of metrorrhagia and menorrhagia cannot be given as yet. I think that Dr Pratt is undertaking the problem in the correct way in that he is gradually collecting evidence by actual observation of the ovaries of patients who have been treated with so-called ovary-stimulating hormone extracts. I think that the point which we made in the paper about species difference is going to explain a lot of the difficulties. To illustrate this I may mention that a purified thyrotropic hormone fraction which we prepared had no maturity effect when tested on immature rats but produced a marked effect on the gonad of the young male dove when tested by Dr Riddle. If our conception of the bipartite nature of the maturity factor is correct it is possible that there may be considerable species difference in regard to gonad sensitivity to one or another part of the maturity complex or to varying mixtures of these.

EMBOLECTOMY OF THE PERIPHERAL ARTERIES

REPORT OF THREE CASES

BERNARD PORTIS, MD

AND

HAROLD A. ROTH, MD

CHICAGO

Removal of emboli from the peripheral arteries is still an infrequent operative procedure, especially when one considers that these vascular accidents are not uncommon, and the results of conservative management are usually followed by serious consequences. The first attempt was made by Sabanejew¹ in 1895, at which time he removed an embolus from the femoral artery but was unsuccessful. Following his example, many surgeons attempted the operation of embolectomy without avail until Labeys² in 1911 and Key³ in 1912 successfully removed emboli from the femoral artery.

A careful review of the literature revealed 131 reported cases of arteriotomy for emboli of the peripheral arteries. The various facts included in these articles will be considered in the discussion.⁴

REPORT OF CASES

CASE 1.—L. S., a woman, aged 42, who entered the Michael Reese Hospital, March 7, 1932, under the service of Dr. William Buchbinder. Had had rheumatic heart disease for many years, and for the past five weeks rapidly lost strength, had a continuous fever, and had gastro-intestinal upsets. On admission, the patient was acutely ill, cyanotic, and exhibited a moderate dyspnea. The lungs showed impaired resonance at both bases. The heart was enlarged to the right, and the apex was at the anterior axillary line. The rate was rapid and the rhythm showed an irregular irregularity. There were also a multiplicity of murmurs heard over the cardiac region. The legs were edematous and the liver was also enlarged.

March 12, at 6 p. m., the patient suddenly complained of severe pain, numbness and coldness in the right leg. The color was more or less ashen and no pulsation was felt in the dorsalis pedis artery. The pain continued through the night, and next morning with increasing evidence of impaired circulation of the extremity. At 3 p. m., when seen in consultation the diagnosis of popliteal embolus was confirmed and immediate operation advised.

Operation was performed under local anesthesia. An incision was made about 8 cm. in length in the right popliteal space and the popliteal artery was carefully exposed. There was a noticeable decrease in subcutaneous bleeding, and an absence of pulsation of the main artery. The field was kept saturated with sodium citrate solution during the entire operation. Small rubber constrictors were applied to the artery and an incision was made into the lumen of the vessel. No blood flowed from the vessel when the proximal constrictor was released, so that a small bore glass tube attached to a suction apparatus was inserted into the proximal part of the incised artery. After a few attempts with the suction, a small clot followed by several small particles of clot was withdrawn from the vessel. The blood soon rapidly flowed from the opening and the constrictors were again tightened. The opening in the artery was closed with a continuous vascular silk suture, so as to cause an approximation of the intimal layers. The

temporary constrictors were then released, and the circulation was reestablished through the popliteal artery.

The patient left the operating room in good condition, with the leg definitely warmer and with less pain. There were frequent attacks of cramplike pain in the calf and foot muscles for several days, but at no time did the leg lose its color or become cold. The patient was up and about after several weeks, had regained sufficient strength to use crutches, and left the hospital, April 30, 1932. She remained in comparatively good health for an individual with a grave myocardial disease until several months later, when she had another cardiac decompensation, developed pneumonia and died.

CASE 2—F L, a woman, aged 27, was admitted to the hospital for the first time, Jan 29, 1932, at which time she had suffered from a right hemiplegia and dysarthria. The physical examination revealed, in addition, a serious cardiac decompensation, mitral stenosis and regurgitation, and auricular fibrillation. Her condition gradually improved, and she left the hospital with a more or less compensated heart and moderate return of motor function of the right side of the body.

The second admission was on Feb 6, 1933, in the service of Dr Solomon Strouse. At this time there were again symptoms referable to cardiac embarrassment and abdominal complaints of attacks of pain in the upper right quadrant, with nausea and vomiting.

The patient was acutely ill, with a temperature of 100.8, respirations 28, a pulse rate of 100, and an irregular irregularity of its rhythm. The heart was enlarged to both the right and the left. Systolic and presystolic murmurs were heard at the apex. The liver was palpable three fingerbreadths below the costal arch, with local tenderness in the region of the gallbladder. There was moderate paresis of the lower right extremity. The diagnosis at this time was similar to that on the previous discharge, with the additional possibility of an engrafted subacute bacterial endocarditis and gallbladder disease.

February 9, at 11:30 p.m., the patient complained of severe pain in her right arm, which soon became cold and clammy, she went into shock and the right radial pulse could not be obtained. The blood pressure on the left arm was 100 systolic, 65 diastolic, but could not be obtained on the right arm. The oscillometric readings showed absence of oscillations in the entire right arm, while they were normally present in the left arm. The deep axillary pulse was felt in the right axillary space, but there was no palpable brachial or radial pulsation. The diagnosis of embolus to the right axillary artery was made. At operation two hours later, a large embolus was found occluding the right axillary artery, just proximal to the circumflex humerus branch. The embolus was removed readily and the artery sutured as described in case 1. The hand and arm immediately became warm and the pain decreased markedly. The following night slight oscillometric readings could be demonstrated in the right arm, and there was a faint pulsation in the right radial at the wrist. On the evening of February 10 the patient complained of severe pain in both legs. The left was definitely cooler than the right. There was no cyanosis, and no oscillometric readings could be obtained from either leg. The diagnosis was made of a riding embolus at the bifurcation of the aorta with more marked interference with the left common iliac than the right although both seemed definitely involved. Surgery seemed contraindicated because of the partial circulation and the inaccessible site of the embolus. The legs continued more or less warm although no deep pulsations of the femoral artery could be determined. By February 12 the pulsations in the right radial practically equaled those of the left. Likewise the oscillometric readings showed practically equal pulsation in both arms and forearms. The surface temperature and histamine test for collateral circulation (Dr Perlow) of both arms were practically equal and normal. The same test showed that the collateral circulation of both legs and thighs was adequate although no pulsations could be elicited in the deep vessels. February 17 at 6 a.m. after a very comfortable night she complained of pain and pressure in her head and suddenly became unconscious and died.

Autopsy was obtained, with the following anatomic diagnosis:

Recent surgical incision of right axillary region and right axillary artery with patent lumen and no evidence of secondary thrombus formation.
Acute verrucous endocarditis of the tricuspid valve.
Healed endocarditis of the mitral, aortic and tricuspid valves.
Stenosis of the mitral and aortic orifices and insufficiency of these valves.
Diastolic endocardial pocket left ventricle.
Hypertrophy and dilatation of heart.
Mural thrombus in left auricle.
Embolus in aorta (iliac bifurcation) almost completely occluding the left common iliac artery.
Multiple infarcts in kidneys.
Pulmonary emphysema.
Slight pulmonary arteriosclerosis.
Chronic passive hyperemia of lungs, liver, spleen and kidneys.
Chronic cholecystitis and cholelithiasis.
Old caseous tuberculosis right lower lobe.
Recent miliary tubercles of lung.

Permission was not obtained to examine the brain.

CASE 3—R S, a woman, aged 62, admitted to the hospital in the service of Dr Leon Bloch, Feb 23, 1933, complained chiefly of recurrent attacks of severe precordial pain with a sense of constriction about the chest and feeling of impending death. The temperature was 100.4, pulse 92, and respirations 18. The patient was somewhat debilitated and appeared moderately ill and cyanotic. The heart was enlarged and the tones were distant. The blood pressure was 130 systolic, 72 diastolic. The peripheral vessels were thickened and tortuous.

She had several attacks of angina while in the hospital, and on March 1 at 5 a.m. complained of severe pain in the right arm which soon became blanched and cold. The pulsations of the right brachial artery were readily demonstrable, but there was no radial pulsation. The oscillometric examination showed a normal response in the right arm but an entire lack of response in the right forearm. A diagnosis was made of an embolus in the right brachial artery at its bifurcation into the radial and ulnar arteries. Operation was started at 7:10 a.m., two hours and ten minutes after the onset. The right cubital fossa was infiltrated with a local anesthetic, the skin was incised and after careful dissection the lower end of the brachial artery was exposed and the embolic occlusion was encountered at the bifurcation. Very dramatically, each pulse wave coursed through the brachial artery and stopped abruptly at the site of embolic lodgment. The mouths of both the radial and ulnar arteries were filled by the embolus, which took the form of a Y. Small rubber constrictors were placed about the brachial, radial and ulnar arteries above and below the embolus. The field was kept saturated with sodium citrate solution. A longitudinal incision was made into the brachial artery and the embolus was extruded. The constrictors were removed for a short period so as to allow a free flow of blood, and then tightened again and the vessel closed by a continuous vascular silk suture. The constrictors were again released and the pulse wave immediately surged through the brachial artery down over both the ulnar and radial arteries so that the radial pulse was then easily felt. The pain immediately subsided and the arm became warm. The oscillometric examination after completion of the operation showed a normal response in the right forearm. The patient unfortunately developed a cerebral embolus March 6, which caused a left-sided hemiplegia and died three days later from bronchopneumonia. The right forearm remained in normal condition and would surely have recovered completely had the cerebral accident not occurred.

COMMENT

The sources of the emboli are usually cardiac in origin arising from thrombi either located on the valves as in vegetative endocarditis or as mural thrombi found in the left auricle associated with mitral stenosis or auricular fibrillation. Occasionally atheromatous ulcerations of the aorta with local mural thrombi may give rise to emboli. Other vascular lesions and operative procedures may serve as a similar source.

The subsequent course of the embolic phenomenon depends on certain underlying factors. The emboli usually lodge at the bifurcation of an artery or at the site of one of its branches. The embolus may occlude

the vessel entirely, or, as frequently occurs, the subsequent thrombus formation and vascular spasm bring about a complete cessation of the circulation through this segment of the vessel. The ultimate changes depend chiefly on the size of the artery, the completeness of the occlusion and, most important, the available collateral circulation. Gangrene is to be expected in most instances if the circulation is not reestablished.

The symptoms produced by the lodgment of the embolus are those of a sudden onset of severe pain in the extremity, associated with pallor, lowered temperature, decreased mobility, and a disappearance of the skin and tendon reflexes. The main vessel or vessels below the site of the impacted embolus show a complete absence of pulsation as demonstrated by palpation, and lack of response in the oscillometer when applied to the extremity at that point. The embolus can sometimes be felt along the course of the artery.

The direct diagnosis of peripheral embolic accidents is based on the presence of preexisting cardiovascular disease, with the onset of the foregoing symptoms, and the presence of physical manifestations already mentioned. This condition must be differentiated from venous and arterial thrombosis, Buerger's disease, intermittent claudication and Raynaud's disease. The differential diagnostic features will not be considered in this paper, as they are usually quite obvious.

The treatment should be surgical, if the main vessel involved is accessible, if seen early, especially before the onset of gangrene, and the collateral circulation seems obviously deficient to maintain life of the extremity.

Local anesthesia is the anesthetic of choice and may be used by either local or peripheral nerve block. The involved vessel is exposed in the region of the embolic occlusion and carefully separated from the surrounding tissues. Soft, small rubber constrictors are placed directly around the artery, above and below the embolus, and are gently tightened so as not to injure the vessel. A longitudinal incision is made in the artery, and the embolus removed with care. The field must be kept saturated with sodium citrate solution during the entire operative procedure. If the embolus has not been definitely located, suction may be used in the open vessel, as was found necessary in case 1. The proximal constrictor is then released, and the blood will at once flow from the artery, if the embolus has been removed. It is wise to remove only the proximal constrictor in order that any adherent clot may be washed out of the vessel and small particles not forced into the distal branches. The constrictors are again tightened and the vessel is closed with continuous vascular silk suture material, so that there is a fine line of eversion of the intima. Subsequent to this, the constrictors are finally removed, to determine the completeness of the hemostasis and the reestablishment of the circulation. The wound is then closed by layers.

PROGNOSIS

The prognosis is dependent on the interval between the onset of the attack and the time of operation. The success of this method of procedure decreases rapidly, with increasing period of time and is usually hopeless after ten or twelve hours. Further, the subsequent course is dependent on the available collateral circulation, the myocardial reserve, and the general condition of the patient.

SUMMARY AND CONCLUSIONS

In three cases of peripheral emboli treated by arteriotomy, the vessels involved were the popliteal,

axillary and brachial. The immediate results were very satisfactory, although two of the patients later developed fatal cerebral emboli. The first patient was able to be around, lived for several months and died from a subsequent cardiac decompensation and pneumonia.

The diagnosis is usually obvious especially after a careful analysis of the early symptoms and the physical conditions and by the use of the oscillometer, which demonstrates the presence and usually localizes the site of the vascular occlusion. Various vascular diseases and local thromboses must be excluded before the best treatment for each case is decided on. Operation should be performed under local anesthesia and as early as possible. The technic described was found quite satisfactory. The surgical treatment is usually successful if the period of time between the onset and the operation is under ten hours, although this is subject to individual variations. The development of gangrene usually necessitates amputation but is frequently fatal because the patient is already in a debilitated condition and the myocardial reserve is necessarily very low.

Key concluded that "An embolus, which causes circulatory disturbances of a threatening character in the upper or lower extremities, ought to be removed by arteriotomy unless there are contraindications. The operation should be done as soon as possible."

Clinical Notes, Suggestions and New Instruments

DERMATO OPTHALMITIS DUE TO THE EYELASH DYE LASH-LURE

CLAUDE E. HARNER, M.D., LONG BEACH, CALIF.

Having observed the report by Greenbaum¹ of a case of dermatconjunctivitis due to Lash-Lure, I am prompted to report three cases that I have seen. One patient was poisoned four years ago with the same dye. In addition to the three cases here reported, another case was seen several years ago in consultation, but adequate notes were not kept, or have been lost, and this case is not reported.

In only one of my cases can the condition be styled merely dermatconjunctivitis, since the lesions involved the eyes in general, producing keratitis and uveitis, and I have classified them as dermatophthalmitis.

REPORT OF CASES

CASE 1—Miss E. N., aged 23, seen in 1929, had the eyelashes dyed about a week previously with Lash-Lure. The eyelids were markedly swollen, so that she could hardly open them. They were covered with many small watery blisters. There was marked chemosis of both the bulbar and palpebral conjunctivae. The corneas were difficult to see but apparently clear. The iris was normal. The pupils were small. There was marked photophobia.

Under treatment, the condition improved slowly. Ten days later a small abscess on the lid of the right eye near the inner canthus was incised. The lids were still quite thickened and the conjunctivae velvety. Vision was right, 6/6—1, left, 6/6. Improved by lenses, it was right 6/4, left, 6/4—1.

The patient was next seen April 2, 1933 after having had her eyelashes dyed at the same beauty parlor the day before. The same dye was used. Both eyes were completely swollen shut. There was marked chemosis of the conjunctivae. The corneas were clear. The iris was normal. I could not get the lids far enough apart to see the interior of the eyes. The following day they were worse, with more swelling of the lids and conjunctivae. The lower lids were pulled up under the upper lids and apparently scratching the corneas. A large

¹ Greenbaum, S. S. Dermatoconjunctivitis Due to Lash-Lure and Eyelash and Eyebrow Dye. *J. A. M. A.* 101:363 (July 29) 1933.

amount of watery secretion, slightly filled with pus, was obtained on spreading the lids apart. The corneas of both eyes were infiltrated with a faint gray infiltration.

April 4, the patient was sent to the hospital with private nurses. They were advised to open the eyelids every few minutes to allow the escape of the irritating fluid. Other treatments were instituted, including atropinizing. After a very stormy course the patient was discharged from the hospital one week after entrance.

In the office, when examined with a slit lamp, it was seen that there was an infiltration of the superficial layers of the corneas and still some edema of the conjunctivae. At various times, abscesses on the edges of the lids appeared, and a chalazion developed necessitating opening and curettage.

The eyebrows had been treated with the dye also, and the same vesicular eruption and tremendous edema occurred in this region. The eyes did not return to normal until May 16, six weeks from the date of application of the dye. Vision at this time was: Without glasses right, 6/5, left, 6/5—2. With correction right, 6/4, left, 6/4—2.

During the patient's stay in the hospital a Wassermann test was made and was negative. She had a mild nephritis. The urine showed a few hyaline casts, acetone plus one, and slight reduction of sugar. The white count was 7,200, with 70 per cent polymorphonuclears.

An interesting sidelight on this case is that the patient is training herself to be a cosmetician and it has been necessary for her to discontinue using this dye on other people, since in handling it she gets an inflammation of the skin wherever it touches.

CASE 2—Mrs E. C., aged 42, seen June 27, 1933, had her eyelashes and eyebrows dyed with Lash-Lure the previous day at 5 p. m. She immediately had great irritation of the eyes, which became worse until in the night the lids began to swell shut, and on this morning the right one was entirely swollen shut and the left nearly so. Lacrimation and photophobia were intense. The lids of both eyes were markedly swollen and edematous and had a crinkly red appearance. The conjunctivae were swollen and red, there was flocculent stringy material in both eyes. The corneas were clear. The pupils were normal.

The following day she was sent to the hospital. There was very little improvement from treatment, and there was some enlargement of the preauricular lymph glands. The corneas developed ulcers on the lower margins. They became more and more infiltrated. The lids at times, were better and again worse. Sterile milk was given intramuscularly and ethylmorphine hydrochloride was used. The eyes were thoroughly atropinized. Multiple abscesses on the lid margins developed. Typhoid vaccine (50,000,000 bacilli) was given intravenously twice at two day intervals. A Wassermann test was reported four plus. A history of venereal infection twenty-six years before was obtained.

The patient was permitted to leave the hospital July 10, two weeks after entrance. When last seen, August 11, the ulcers had entirely healed but had left fairly large leukomas especially on the right eye. Vision was right 6/60, left 6/750—3. Slit lamp examination of the right eye showed deposits of pigment on the anterior surface of the lens and also some on the posterior corneal endothelium. There was a small posterior synechia. There was no deposit on the lens of the left eye. The fundi of both eyes were apparently normal.

CASE 3—Mrs H. E., aged 28, seen, July 29, 1933, had her eyelashes dyed with Lash-Lure three days before. The following morning she had marked inflammation, the eyes being swollen shut. She was under the care of a general physician until referred to me. The lids of both eyes were swollen. There was maceration of the integument of the lids. The corneas were clear. The iris was normal. The conjunctivae were markedly injected. There were marked lacrimation and photophobia. Under treatment the patient improved rapidly and from a telephone conversation with her I learned that the eyes were quite normal within a week.

COMMENT

One is impressed that there is a distinct allergic factor in the production of this condition. Patient 1 had two distinct severe reactions four years apart. Also she develops a localized

dermatitis when using the dye on other patrons of a beauty parlor in which she is employed.

Patient 2, although having a definite syphilitic infection, which may or may not have accentuated the severity of the symptoms, on close questioning admitted that she frequently had eczemas and skin irritations from the use of various cold creams and other cosmetics.

SEVERE EYE SYMPTOMS DUE TO DYEING THE EYELASHES

OLIVER P. BOURBON, M.D., LOS ANGELES

As dyeing the eyelashes is a new fad of beauty parlor patrons, I am reporting this case for the purpose of calling attention to its dangerous possibilities. I have seen but one similar report.¹

The dye used in this case has for its trade mark "L'arieuse" is called "Godefroy's French Coloring for Hair and Beard," and is manufactured by the Godefroy Manufacturing Company, St. Louis. The statement is made on the container that it is "compounded according to the French formula." It is also stated that "the dye is somewhat perishable and must be consumed within fifteen months from the date stamped below" the expiration date for this particular bottle being May 15, 1933. The dye was used in this case on July 8, 1933, almost two months after the expiration date which the manufacturers had marked on the bottle, but whether the age of the dye had anything to do with the ill effects produced is a matter of conjecture.

REPORT OF CASE

Miss D. P. consulted me, July 9, complaining that her eyes were much swollen, with aching and burning and some thick discharge but no severe pain. She had her eyelashes dyed early in the afternoon of the day before. She stated that the beauty parlor operator let some of the dye get into her eyes and that soon after returning home and within two or three hours after the treatment her eyes became swollen, red and watery.

Examination showed a marked edema of the lids of both eyes, the edema extending downward into the cheeks. There was much chemosis of the conjunctiva with a severe congestion and considerable stringy secretion. The cornea of each eye was clear. The edema, chemosis and congestion were of such a degree that the patient could barely find her way about. While no history of former attacks was given, she was exceedingly nervous and the possibility of a severe angioneurotic edema was considered. An ointment of phenacaine with epinephrine was prescribed and directions were given for applying hot moist compresses to the eyes.

The next day the right eye was better, but the left eye was much more edematous and the compresses were changed to ice cold moist compresses of a magnesium sulphate solution. Gradual improvement continued for one week when the patient returned with a severe exacerbation. The eye lids were now so edematous that it was impossible for her to open her eyes. The lids had to be forcibly separated in order to remove the stringy secretion. Hot compresses of a magnesium sulphate solution and 0.5 per cent zinc sulphate ointment were prescribed.

Recovery was uneventful, the edema and secretion gradually growing less, the congestion of the conjunctiva being the last to disappear. The patient was dismissed August 4.

COMMENT

The profuse stringy secretion was evidently due to an excessive mucoid secretion caused by the chemosis and irritation of the conjunctiva and was not due to infection.

Allergic sensitiveness, the chemical irritation and toxic effect of the dye and angioneurotic edema were all considered.

The severe edema and chemosis that appeared so shortly after the dye was used was strongly suggestive of an allergic sensitiveness to the dye.

The prolonged period of the attack, the severity of the congestion, the gradual subsidence of the edema and chemosis and the fact that the conjunctive symptoms were the last to disappear

¹ See Case 3, S. S. Brown, *California Medical Journal*, 1933 (July 29), 1933.

would indicate that while an allergic sensitiveness to the dye was a possible causative factor it was not the only cause of the severe reaction

The picture as a whole strongly indicated a combined chemical irritant and the absorption of material that had a pronounced local toxic effect

EYELASH DYE (LASH LURE) DERMATITIS WITH CONJUNCTIVITIS

R C JAMIESON MD DETROIT

The report by Greenbaum¹ of a case of dermatitis and conjunctivitis due to eyelash dye has prompted the addition of this case to those on record in which eyelash dye (in this case also Lash-Lure) was the excitant

The use of dyes on eyelids and eyebrows would seem to the public a simple and harmless procedure but to the dermatologist even the most trifling and apparently innocuous agents must be considered as a possible cause in searching for the etiology in mild chronic cases of dermatitis about the eyes face and neck in women. These cases are encountered more and more frequently, and each new cosmetic added to the already long list adds one more possible exciting agent

In Bab's² recent article he mentions a number of cosmetics and dyes used on eyelashes eyebrows or skin which are known to produce dermatitis and even conjunctivitis. Henna also which is frequently used to dye the eyebrows and eyelashes was the causative agent in six cases reported by him

The case reported here, of a woman aged 40 was similar in most respects to those already reported. Five days before examination by an ophthalmologist eyelash dye (Lash-Lure) had been applied. No preceding sensitization test had been made. Three days after the application the eyelids became red swollen and irritated. With the usual bland applications she improved during the next two weeks, but at the end of that time the eyelids and adjacent skin areas again developed an acute inflammation accompanied by conjunctivitis. The entire clinical picture at that time was one of dermatitis venenata, invading the eyelids, forehead, cheeks and conjunctivae. Sensitization tests proved negative to everything except Lash-Lure

During the next two months the course of the condition was that of acute dermatitis with conjunctivitis, improving and recurring at intervals, with no other possible source of irritation except the original excitant. Persistent protection of the skin and the application of bland and soothing preparations finally succeeded in establishing a cure

This case appears to have been unusually severe and the protracted course (three months) would indicate that all cases of this type are possibly serious, considering the long incapacitation and the possibility of corneal ulcer or other ophthalmic complications

CORNEAL ULCERATION FOLLOWING USE OF LASH LURE

A W McCALLY MD A G FARMER MD AND L C LOOMIS MD
DAYTON OHIO

There has been much agitation recently against the unbridled use of harmful cosmetics, and many case reports have appeared demonstrating some of the consequences of this practice

We report a case in which a woman had her eyebrows and eyelashes dyed with a preparation called Lash-Lure, a product manufactured in Los Angeles by the Lash-Lure Research Laboratory, Inc. As the ingredients of the cosmetic were unknown and could not be learned from the local beautician who applied it an analysis was made by a competent chemist. He qualified his report by stating that the dye was one of the paraphenylenediamine group. No neutralizing antidote was known and no report of similar cases could be found in the literature as a guide to treatment at the time the patient came under observation. Since then a report of a somewhat similar case though apparently without such extensive involvement,

has been made by Greenbaum¹. Another material difference between Dr Greenbaum's case and the one now reported lay in the time of development of symptoms, being twelve days in his case and immediate and severe in the one now under discussion

REPORT OF CASE

A woman, aged 38, seen on the morning of May 18, 1933, stated that on the afternoon of May 17 she visited a local beauty parlor, where her eyebrows and eyelashes were "touched up." A certain soap, dye and other applications were used. Instead of a minor treatment, as she had expected she was amazed to find it quite an elaborate procedure accompanied by smarting and irritation of the eyes. She had never had a previous application of dyes of any kind, though she had occasionally visited the beauty parlor for other cosmetic treatments. Her eyes smarted and pruned severely on her way home. Within two hours the lids were completely swollen shut and she was unable to open them. The eyes became very red, accompanied by profuse lachrimation and photophobia. The pain increased accompanied by a severe itching, more marked in the right eye. Her nose felt "stuffy and runny," with symptoms of a cold. The skin of her face and brow felt greatly irritated. There was no history of previous eye trouble of any kind and no allergic history except that she had always had a "tender skin."

On her arrival home she flushed her eyes with boric acid solution several times and instilled 10 per cent solution of mild silver protein and ointment of yellow mercuric oxide. She had a bad night and her eyes were worse the next morning

When the patient was first seen the morning after the application of the dye, there was a beginning edematous dermatitis of the face and forehead, marked edema of the lids marked chemosis with folds of conjunctiva protruding between the lid margins and severe conjunctival and ciliary congestion. The pupils were small and only slightly active to light, and the iris markings were somewhat blurred, the iris appearing edematous. There were two areas on the left cornea which showed denudation of the superficial layers while the right was stippled over its entire area. The fundi appeared normal through the somewhat hazy media. Vision was blurred, more so in the right eye, though objects could be distinguished. The temperature was normal. Treatment was entirely symptomatic consisting of flushings with boric acid solution cold applications, butyn drops and holocaine ointment for pain, acetylsalicylic acid for headache and emulsion of scrophrine tartrate solution for the edema of the nasal mucous membranes

The beautician on being informed of the case visited the patient and applied milk compresses to the face and lids

May 19, the chemosis had markedly subsided but otherwise the condition had progressed unfavorably. The skin condition had become worse and was very irritating. The ocular congestion had not subsided except for the chemosis posterior deposits were present on Descemet's membrane, both corneas were more hazy pain was more marked in the right eye, vision was much impaired and both globes were tender to palpation. Tension was not increased. The discharge had changed to a stringy exudate. An attempt to dilate the pupil was made at this time with homatropine and atropine. It was found that with difficulty, only incomplete dilatation could be obtained and there was a tendency to contract quickly. The fundi could not be seen. Irrigations, butyn and compresses were the only measures affording relief butyn affording complete relief of the pain in the eyes for varying periods. Rest could not be obtained by the usual sedatives. A dermatologist was called to care for the skin condition. Lassar's paste and starch compresses were prescribed with some symptomatic relief. Conditions remained about the same on the 20th. The patient was hospitalized on the 21st in order to secure full nursing care. The pupils were fairly well dilated at this time. In the evening the pain became more severe requiring frequent instillations of butyn. The pupils again became small both corneas very hazy and vision practically absent except for light perception. The anterior chambers were of average depth. Tension was difficult to estimate because of the edema present, but it seemed slightly increased

May 22 the pain was still severe, particularly in the left eye whereas the right had previously been the more painful. Ten

1 Greenbaum S S. Dermatoconjunctivitis Due to Lash Lure and Eyelash and Eyebrow Dye. J A M A. 101:363 (July 29) 1933

sion still seemed increased on palpation and paracentesis was considered. McLean tonometer readings, however, were normal in both eyes. Fifty per cent dextrose was given intravenously, and eye medication was restricted to sterile olive oil and atropine. This, however, was not well borne. Pain could not be relieved by codeine or morphine, the latter exciting the patient, and return to butyn was necessary. It was thought that the frequent use of butyn might be aggravating the ocular condition. Butyn and atropine ointment were used. Filaments appeared on the left cornea and there was a marked lessening of pain. That night the patient rested for five hours, the best relief she had had since the onset of her trouble. On the 23d, a large central ulcer appeared on each cornea. The ulcers were touched with tincture of iodine, and metaphen 1 5,000 was used. These were improved the next morning but on the evening of the 24th there were two more small ulcers on the right cornea below and one appearing on the left. These were cauterized lightly and touched with tincture of iodine. Cultures showed *Staphylococcus citreus*. The following day the patient was resting better and had slept fairly well with chloral hydrate by rectum. The ulcer margins, however, seemed to be extending and it was decided to cauterize these with the actual cautery. On the 26th there were two more small new ulcers on the right cornea and one more on the left. All of these smaller fresh ulcers were thoroughly cauterized on this day. It was found that their bases were deeply situated. The large central ulcers were clean and apparently healing. They were not cauterized but their edges were threaded with silver nitrate, 1 per cent, to stimulate them. From this time there was a slow but steady improvement. The edema of the lids subsided considerably but their margins remained somewhat reddened. Ammoniated mercury ointment, 3 per cent, was applied to this region for a few days with some improvement. Vision was reduced to light perception because of the impaired media but the pain was very much less. The patient was, however, extremely nervous and restless and, though many sedatives were used, none were successful in procuring rest, which amounted to from fifteen minutes to two hours a night, accompanied by hallucinations. June 1, a suppurating chalazion was incised and drained and on that date she was moved from the hospital to bed rest at home.

The ulcers improved slowly with occasional applications of tincture of iodine, instillations of metaphen, 1 5,000, solution, atropine, and the use of hot applications. Later mercurochrome paste and trichloroacetic acid were occasionally applied. June 4, they were treated with the actual cautery.

June 5, a generalized bright red papular dermatitis began to appear on the body. This was thought to be due to atropine. Homatropine, supposedly less toxic, was substituted, as scopolamine was feared in this case and it was thought advisable to continue a mydriatic. The skin condition all the way through had been a major problem and no effective remedy had been found. The appearance of this new rash was very annoying.

The patient, however, seemed to be making some progress until June 10, when she began to develop severe pain lasting for an hour or so each morning about 5 o'clock and not relieved by butyn. The tension in both eyes began to increase and the ulcers which had been improving, began to retrogress, the edges and bases becoming necrotic. June 14 a bilateral paracentesis was done with a keratome in both lower corneal segments. Relief of the severe pain was obtained to a considerable degree but the corneal ulcers were not influenced, though both wounds were kept open for several days. The right cornea was apparently becoming necrotic though the left seemed to be improving slightly. June 18 a second paracentesis was done on the left corner which had closed. On the 20th there was a partial slough of the right corner, involving all but a zone about the limbus and extending to the deeper layers. This was followed by a staphyloma and a dense opacity with vascularization. Tension subsided in the right eye but persisted in the left although the wound was kept open as long as possible. June 25 a third paracentesis was done on the left eye. This also failed to improve the condition of the left cornea which sloughed like the right but over a smaller area.

The skin condition improved markedly about June 18 when potassium permanganate solution 1 5,000 in the form of compresses on the face and affected portions of the body was begun.

All eye medication was stopped at the same time except for irrigations with physiologic solution of sodium chloride or potassium permanganate, 1 5,000, solution. Owing, however, to the increase of ocular pain, the eye medication was resumed and consisted of homatropine and butyn. Skin patch tests were made with atropine, butyn and metaphen, but all were negative. Hordeola and furuncles played an annoying part in the case after several weeks. Foreign protein was used in courses throughout the acute illness. Routine urinalyses and blood examinations, including Wassermann and Kahn tests, were negative except for an occasional trace of albumin, a few pus cells, and slight lowering of hemoglobin and the red cell count.

The most marked feature in the pathologic changes in this case was the intense edema of all structures, particularly of the cornea, ciliary muscle and iris. This apparently interfered markedly with normal circulation. There was simply a disintegration of the corneal stroma. Hypopyon, ordinarily seen in the presence of such marked corneal changes due to bacterial invasion, was absent.

At the present time the patient is in good physical condition, the skin is clear and the eyes are quiet, though there is still slight ciliary congestion. The right cornea has a large dense opacity, which will permanently obstruct vision, the left has a less dense opacity in the lower half and enough infiltration above to restrict vision to light perception, as in the right eye. We are, however, still hoping for enough clearing of the left cornea to permit some vision, perhaps with the aid of an optical iridectomy. The patient has displayed wonderful fortitude and is in remarkably good spirits. She is entering into a number of her usual social and household activities and is now considering the braille system. She is especially interested in doing all in her power to stop the use of harmful cosmetics and in preventing similar and other injuries happening to other women from the same cause.

Fidelity Medical Building

Council on Pharmacy and Chemistry

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING
REPORT PAUL NICHOLAS LEECH Secretary

REPORTS OF THE COUNCIL

CALUMBA-AGAR AND RHEUM-AGAR (REIN- SCHILD CHEMICAL CO.) NOT ACCEPT- ABLE FOR N N R

Calumba-Agar and Rheum-Agar stated to be agar 'impregnated' respectively with fluid extract of Calumba, N F and fluid extract of Rheum, U S P, were presented for consideration of the Council by Reinschild Chemical Company, New Rochelle, N Y.

On the label of Calumba-Agar occurs the statement "Each teaspoonful represents 2 C C (M 32) Fluid extractum Calumbae N F." On the label of Rheum-Agar occurs the statement

Each teaspoonful (weighing only 1 gram) represents 1 C C (M 16) fluid extractum rhei U S P. In the information submitted to the Council no evidence was given that these products contained the claimed amounts of calumba and of rheum. In the case of Calumba-Agar the product was stated to be prepared by impregnating 1000 Gm of agar with 2000 cc of Calumba U S P VIII. In the case of Rheum-Agar the product was stated to be prepared by impregnating 1000 Gm of agar with 1000 cc of Fluid Extract of Rheum U S P.

Combinations of agar with other substances are hardly justified unless the administration of the combination possesses some distinct advantage over that of the separate ingredients. The Council's referee reported that he knew of no special advantage in administering rhubarb or calumba with agar yet he was inclined to recommend that these products be accepted since he could find no serious objection to their use. Being skeptical as to the accuracy of the quoted statements from the label the referee recommended that Calumba-Agar and Rheum-Agar be accepted provided (a) that the firm could submit satisfactory evidence

that each of these contains the full amount of active ingredient stated on the label, (b) that no special claims be made for the therapeutic value of either combination—in other words that no special claim for either should be made because it is administered with agar, and that the claims for Calumba Agar and Rheum-Agar do not exceed those allowable for calumba and for rhubarb, and (c) that the advertising be revised to omit reference to unaccepted articles. The Council adopted the referee's recommendation.

When informed of the action of the Council concerning these two preparations, the Reinschild Chemical Company wrote that it had submitted the method of manufacture from simple standard U S P and N F preparations, that these are so simple as to be considered *prima facie* evidence as to their composition, and that the Council has facilities for determining their potency and is at liberty to do so. As has been stated repeatedly, the burden of proof lies on the manufacturer.

It is not the business of the Council to test every preparation that is submitted to it. The Reinschild Chemical Company has not submitted satisfactory evidence that Calumba-Agar and Rheum-Agar contain the full amounts of active ingredients stated on the labels nor met the other conditions for acceptance of the products, the Council, therefore, declared these preparations unacceptable for New and Nonofficial Remedies.

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG, Secretary

DEAN'S EVAPORATED MILK—VITAMIN D ADDED (ADDED VITAMIN D CONCENTRATE PREPARED FROM COD LIVER OIL)—150 STEENBOCK VITAMIN D UNITS PER 145 OZ

Manufacturer—Dean Milk Company, Chicago

Description—Evaporated milk, the same as Dean's Quality Evaporated Milk (THE JOURNAL, Aug 6, 1932, p 477) with 150 Steenbock Vitamin D units (vitamin D concentrate prepared from cod liver oil) per 14½ ounces.

Preparation—A definite quantity of cod liver oil concentrate (ViteX, National Oil Products Company) in vegetable oil solution, is introduced into the evaporated milk as it leaves the evaporating pans. The mixture is homogenized, cooled, thoroughly agitated and canned by the usual procedure.

Vitamins—The vitamin D concentrate and the vitamin D fortified milk are regularly tested biologically.

Claims of Manufacturer—For general cooking, baking and table uses and for infant feeding. The mixture of equal parts of the evaporated milk and water is not below the legal standard for whole milk. The curds formed in the stomach are smaller, softer and more readily digestible than those from raw or pasteurized milk.

KING ARTHUR FLOUR NEVER BLEACHED

Manufacturer—Sands Taylor & Wood Co, Boston

Description—A spring wheat 'short patent' flour, not bleached.

Manufacture—Selected spring wheat is cleaned, scoured and milled and chosen flour streams are blended by essentially the same procedure as described in THE JOURNAL, June 18, 1932, page 2210.

Claims of Manufacturer—Never bleached.

BEECH-NUT STRAINED CARROTS

(SLIGHTLY SEASONED WITH SALT)

Manufacturer—Beech-Nut Packing Company, Canajoharie, N. Y.

Description—Sieved carrots retaining in high degree the natural vitamin and mineral values, seasoned with salt.

Manufacture—The carrots are washed, and are scraped and trimmed by hand, are sliced, weighed into steam jacketed glass lined kettles containing mechanical agitators with a minimum amount of water and 0.5 per cent by weight (of the carrots and water) of salt is added. The air is exhausted the carrots are steam cooked until soft, then passed through two enclosed metal strainers containing an atmosphere of steam. Coarse material is discarded. The strained material in 'vacuum' in glass-lined kettles is brought to the desired consistency, flowed to holding tanks, heated to 70 C and automatically sealed in jars in "vacuum," which are heated to 115 C for one hour and cooled.

Carbohydrates other than crude fiber (by difference)	5.9

Calories—0.3 per gram, 9 per ounce.

Vitamins—The method of preparation efficiently protects the natural vitamin values.

Claims of Manufacturer—Especially intended for infants, children and convalescents and for special smooth diets. Only warming is required for serving. The natural mineral and vitamin values are efficiently retained.

INSTANT POSTUM

Manufacturer—Postum Company, Inc., New York

Description—Dried water extract of a blend of roasted wheat bran, whole wheat molasses and malted wheat flour.

Manufacture—The bran, malted wheat flour and molasses are roasted in a coffee roaster, the wheat is separately roasted, the two roasts are blended in proper proportions. The blended cereals are extracted with hot water, the extract is clarified by centrifugating, evaporated to dryness in "vacuum" crushed and automatically packed.

Claims of Manufacturer—For the preparation of table beverage with water or milk, instantly miscible. Contains no stimulating ingredient.

MCCORMICK'S BEE BRAND NUTMEG MCCORMICK'S BEE BRAND SELECT WHOLE NUTMEGS

Manufacturer—McCormick and Company, Inc., Baltimore

Description—Whole and ground nutmeg (dried seed of *Myristica fragrans* Houtt, deprived of its testa). The whole nutmeg is coated with lime.

Manufacture—The nutmeg or ripe seed of an evergreen tree cultivated in Singapore, Penang, Sumatra, Java and the West Indies is collected after falling to the ground. The husk and mace are removed, the nutmeg in the shell is dried on mats in the sun or with fire heat for from eight to ten days. The shells are broken and removed, the kernels or seeds are dipped in milk of lime for protection against insect attack. They are

assorted according to size, exported and packed whole or ground in cartons or tins at the packing plant

(a) DAY STAR BEST PATENT FLOUR
(BLEACHED)

(b) I H BEST PATENT FLOUR (BLEACHED)

(c) SPLIT SILK BEST FLOUR (BLEACHED)

(d) THUNDERBOLT HARD WHEAT FLOUR
(BLEACHED)

Manufacturer—The Ismert-Hincke Milling Company, Kansas City, Mo

Description—(a) and (b) Hard winter wheat patent flour, bleached

(c) Hard winter wheat "standard patent" flour, bleached

(d) Hard winter wheat "straight" flour, bleached

Manufacture—Selected wheat is cleaned, washed, tempered and milled by essentially the same procedures as described in THE JOURNAL, June 18 1932 p 2210 Chosen flour streams for the patent flours and all the flour streams for the straight flour are blended and bleached with nitrogen trichloride ($\frac{3}{4}$ ounce per 196 pounds) and with a mixture of benzoyl peroxide and calcium phosphate ($\frac{1}{2}$ ounce per 196 pounds)

Claims of Manufacturer—For bread baking

VITAMIN D FORTIFIED PASTEURIZED MILK
(150 VITAMIN D UNITS PER QUART)
ADVERTISING OF SANITARY
FARM DAIRIES, INC

Distributor—Sanitary Farm Dairies, Inc, St Paul

Description—Advertising for bottled pasteurized grade A cow's milk fortified with vitamin D (vitamin D concentrate prepared from cod liver oil), contains 150 Steenbock vitamin D units per quart

Preparation—The milk complies with the analytic and bacteriologic requirements specified by the laws of the state of Minnesota and the city of St Paul and other municipalities in which it is distributed

See this section for Vitamin D Fortified Pasteurized Milk of W J Kennedy Dairy Company, Detroit, for description of fortification with vitamin D (THE JOURNAL, July 1 1933 p 34) The milk is pasteurized by the holding method (61 C for thirty-two minutes) and immediately cooled to 4 C and automatically bottled The bottles are cleaned with 100 parts of chlorine per million parts of water which is forced into the bottles by pressure pump, the bottles are allowed to drain in an inverted position The bottles are closed with a seal cap and a hood cap held in place by wire

Vitamins—The vitamin D concentrate used in the preparation of this vitamin D milk and the fortified milk are regularly tested biologically at a biologic laboratory approved by the Department of Agriculture of the state of Minnesota Chemical investigation shows this vitamin D fortified milk to be a reliable antirachitic agent

Claims of Manufacturer—A vitamin D fortified antirachitic fortified milk having the natural flavor and food values of

standard pasteurized milk One quart is equivalent in vitamin D content to $2\frac{1}{2}$ teaspoonfuls of good grade cod liver oil (60 Steenbock vitamin D units per teaspoonful)

STOKELY'S FINEST PEAS AND CARROTS

Manufacturer—Stokely Brothers and Company, Inc, Louisville Ky

Description—Cooked, fresh, diced carrots and peas

Manufacture—The cooked carrots (washed, peeled, assorted and diced) and the peas (prepared essentially by the same procedure as described for Stokely's Lima Beans (THE JOURNAL, Oct 7, 1933, p 1155) are admixed in definite proportions by machine just before the blanching operation The mixture is filled into cans, covered with brine sealed, processed for a definite period at 115 C, and immediately cooled

CLAPP'S ORIGINAL BEEF BROTH
(SEASONED WITH SALT)

Manufacturer—Harold H Clapp, Inc, Rochester, N Y

Description—Cooked beef broth containing salt for seasoning

Manufacture—Government inspected and passed beef is cooked at 100 C for five hours in a dilute salt solution The beef broth formed is allowed to stand over night, is strained through gauze and is automatically packed and sealed under vacuum in glass jars, which are processed at 116 C for one hour

ADDED) (BLEACHED)

(b) GILSTER'S FEATHERLITE PLAIN FLOUR
(PHOSPHATE ADDED) (BLEACHED)

(c) GILSTER'S MOTHERS JOY PLAIN FLOUR
(PHOSPHATE ADDED) (BLEACHED)

Manufacturer—Gilster Milling Company Mill Steelville Ill Office Chester Ill

Description—(a) Bleached soft winter wheat short patent flour containing 0.5 per cent added calcium acid phosphate

(b) and (c) Bleached soft winter wheat long patent flour containing approximately 0.5 per cent added calcium acid phosphate

Manufacture—Selected soft winter wheat is cleaned, scored, tempered and milled by essentially the same procedures as described in THE JOURNAL, June 18 1932 p 2210 Chosen flour streams are blended, bleached with a mixture of calcium phosphate and benzoyl peroxide and with chlorine and admixed with 0.5 per cent by weight of calcium acid phosphate

Claims of Manufacturer—100 percent calcium and phosphate

IRRADIATED ERGOSTEROL, VITAMIN D AND TOXISTEROL

The discovery that irradiation of many food materials with ultraviolet rays would induce antirachitic properties in these foods paved the way for a line of research that has proved extremely promising for the ultimate chemical characterization of vitamin D. When it was found that the curative potency resided in the unsaponifiable fraction of irradiated oils, attention was naturally directed to cholesterol. However, it was soon shown that a contaminant was responsible for the photochemical activation of supposedly pure cholesterol and that this substance was ergosterol. In the early enthusiasm over this observation, irradiated ergosterol was hailed as the antirachitic factor itself or at least as the provitamin D. This material was early shown to possess extraordinary therapeutic action in the prevention and cure of rickets, later it was also found to be toxic if used in very large doses.

Certain changes of a chemical and physical nature take place when ergosterol is exposed to light of short wavelength. The irradiated product has a different melting point, solubility and optical rotation, and the absorption spectrum shows a marked transformation accompanied at the extreme by the loss of all antirachitic potency. It appears that the photochemical change has produced a series of products. In the course of one of the successful efforts to crystallize vitamin D, Windaus and his co-workers at Gottingen have obtained a series of isomers of ergosterol, viz., lumisterol, vitamin D, and suprasterol I and II. Subsequently, Windaus, von Werder and Luttringhaus¹ demonstrated still another product, tachysterol, in the mixture of irradiation products of ergosterol. It does not possess antirachitic activity until irradiated further, but, in contrast to the other nonpotent components of the irradiation mixture, it is definitely toxic.

A recent report by Laquer and Linsert² describes the isolation of still another product from the mixture of

isomers produced by irradiating ergosterol, to which they give the name toxisterol. This is produced by further irradiation of vitamin D and possesses far more marked toxic properties. Whereas 0.025 microgram of vitamin D will initiate healing in the rachitic bone, as much as 5 micrograms of toxisterol is required. The maximum absorption by toxisterol occurs at about 250 millimicrons and, since ergosterol, after being irradiated until no antirachitic activity remains, also shows this point of maximum absorption, it appears likely that the newly discovered sterol may constitute a large part of the product of extreme irradiation of ergosterol.

The difficulty of making clean-cut chemical separations of the isomers of the sterols is well recognized. It is more than likely, therefore, that the antirachitic property of toxisterol is due to contamination with vitamin D. It is certain that, if the early observations on the toxicity of toxisterol are substantiated, there is at hand an explanation for the untoward effects produced by supertherapeutic doses of irradiated ergosterol. Indeed, Laquer and Linsert point out the advisability of making therapeutic preparations in the future from crystalline vitamin D rather than from irradiated ergosterol in order to avoid the toxic effects of certain of its isomers which are inevitably produced in the photochemical process.

THE CENTENARY OF THE DISCOVERY OF DIASTASE

The present year represents the centenary of the discovery of diastase, an incident of great importance for the biologic sciences and not without considerable significance for medicine. In 1830, Dubrunfaut prepared an extract of malt that converted starch into sugar just as since early in the nineteenth century strong acids were known to do. His paper was really the first account of the action of an enzyme in solution.¹ Three years later, in 1833, Payen and Persoz² precipitated by alcohol from such extracts a substance that could be dried and preserved and that had a powerful action on starch. This they called "diastase." The term has continued in use in France almost to the present time as synonymous for the substances more commonly designated today as enzymes. Of course, the production of sugar in the process of malting was known before 1833, but the modern scientific history of enzymes and their action really commences with the researches of Payen and Persoz on diastase.

Today, at a time when enzymes seem to be recognized to a greater extent than ever before as possible potent agents in the biologic process of disease as well as of health, it may seem worth while to recall a few of the steps that have led to the current interest in those

¹ Windhaus, A., von Werder, F. and Luttringhaus, A. *Ann. d. Chem.* 499: 188, 1932.
² Laquer, F. and Linsert, O. *Klin. Wchnschr.* 12: 73 (May 13) 1933.

¹ Some account of the fundamental facts here referred to will be found in Bayliss, W. M. *The Nature of Enzyme Action* London: Longmans Green & Co., 1911.
² Payen and Persoz. *Memoire sur la diastase et les principaux produits de ses reactions*. *Ann. de chimie et de physique* 53: 73, 1933.

unusual specific biochemical catalysts that are termed enzymes. In the early period, as the number of recognized diastase-like products grew, they were designated in general as "ferments" on account of similarities in their activities to those of alcoholic fermentation. Presently substances of the diastase type were distinguished as "soluble" or "unorganized" ferments in contradistinction to living organisms, like yeast, to which the name "organized ferments" was then applied. The inevitable confusion led the Heidelberg physiologist Kuhne in 1878 to suggest a new name. The publication in which this first occurred is so rare, and so few students have actually read it, that we venture to repeat the interesting passage, in translation:

The latter designation [i.e., formed and unformed ferments] has not gained general acceptance, in that on the one hand it was objected that chemical bodies such as ptyalin and pepsin could not be called ferments, since the name was already given to yeast cells and other *organisms* (Brucke), while on the other hand it was said that yeast cells could not be called *ferments*, because then all organisms including man, would have to be so designated (Hoppe-Seyler). Without stopping to inquire further why the name excited so much opposition, I have taken the opportunity to suggest a new one, and I give the name *enzymes* to some of the better known substances, called by many "unformed ferments." This is not intended to imply any particular hypothesis, but it merely states that *εν ζυμην* (in yeast) something occurs that exerts this or that activity, which is considered to belong to the class called fermentative. The name is not, however, intended to be limited to the invertin of yeast, but it is intended to imply that more complex organisms, from which the enzymes, pepsin, trypsin, etc., can be obtained, are not so fundamentally different from the unicellular organisms as some people would have us believe.³

Thus by definition enzymes have become the catalysts produced by living organisms. The controversy as to whether an essential difference existed between organized and unorganized ferments was settled by Buchner in 1897. He proved that by the application of great pressure to ground up yeast it was possible to express a liquid that contained no cells but possessed all the fermentative properties of the original yeast. Since that time, by similar means, many of the "ferments" have been extracted from living cells, and it has been amply demonstrated that, although these ferments are produced by the living cells, once they have been produced life itself is unnecessary for their actions. Cameron⁴ has further pointed out that all these compounds are therefore of one class and may be called ferments or enzymes. Neither term is satisfactory. Most of them do not produce an effervescence resembling boiling and the vast majority of them do not occur in yeast. They produce catalytic actions and therefore they may be more correctly termed biochemical catalysts or biocatalysts. In any event an enzyme, ferment or biochemical catalyst is a catalyst produced by a living cell but whose action is independent of the living cell that produces it. Paven and Peroz could scarcely have imagined that within a cen-

tury hundreds of volumes would be devoted to the category of substances of which their newly described diastase was the first more clearly defined representative.

OHIO AGAIN ACTS TO AID ITS HOSPITALS

The increasing toll of motor vehicle accidents continues to place an unwarranted burden on hospitals. As previously mentioned in these columns,¹ hospitals receive compensation for only a small portion of the expense they incur in caring for patients who have been injured in accidents from this cause. These are not patients of the hospitals' choosing. If an injured person is brought to a hospital, the institution has no alternative but to accept him, regardless of how great an expense may be incurred in treating him or of how unlikely it may be that the patient or any other person will pay the costs of the required service. With the considerable losses of income from private patients and from endowment investments which most hospitals have suffered in the last few years, this burden of serving without adequate remuneration the casualties of motor transportation has been the more keenly felt.

Some attempts have been made in several states to remedy this situation. It was thought that the Massachusetts law compelling all owners of motor vehicles to carry liability insurance might greatly relieve the hospitals of that commonwealth, but such has not been the case. The legislatures of several other states following the leadership of New Jersey, have enacted lien laws which provide the machinery by means of which physicians, nurses and hospitals may secure payment of their legitimate charges for services rendered patients for injuries caused by the fault or negligence of other persons. These lien laws are good as far as they go but at best their operation is cumbersome, and, as far as motor vehicle accidents are concerned they leave uncovered all those cases in which responsibility for the accident cannot be placed on the owner of the car who is assumed by the patient to be responsible for the accident. Accidents in which responsibility cannot be fixed form no small percentage of all those with which hospitals have to deal.

The Ohio Hospital Association deserves great praise for its efforts exerted over several years to secure the enactment of a law framed in an attempt to solve this problem. That organization already had to its credit a law which has been in effect for several years which provides adequate compensation for the hospital care of workmen injured in industrial accidents. As a result the hospitals of Ohio are assured remuneration in such cases equalling or closely approximating their costs. Using some features of this law as a pattern the Ohio general assembly at its last session passed in act to provide reimbursement for hospitals on account of

⁴ Cameron, A. T. A Textbook of Biochemistry. New York, Mac-

¹ J. Caring for the Victims of Automobile Accidents. J. A. M. A. 99:1175 (6) 1912.

expenses for the care of indigent persons injured in motor vehicle accidents "

The main purposes of the law are, in effect, as follows. Indigent patients are defined as those persons who have suffered motor vehicle injuries and are unable to pay in part or in full for the hospital service they obtained in relation to such injuries. Hospitals to comply under the act must be organized and operated not for profit. The per diem cost for caring for patients is that determined by the Industrial Accident Commission and used as a basis of compensating them for the care of the victims of industrial accidents. The fund that is established to meet these hospital costs is derived from the annual license tax assessed against the owners of all motor vehicles registered in the state. The law was passed in June, 1933, and is to be in full force and effect until March 1, 1935.

The effect of this legislation is that hospitals may secure from state funds remuneration for the care of all victims of motor accidents who are unable to pay for the hospital care they receive or for whose injured condition no other person who can pay is responsible. Under its provisions, however, a hospital is left with the problem of collecting, if it can, in those cases in which responsibility for a motor accident lies with a vehicle owner who is financially able to pay the hospital or who has insurance protection. In case settlement is made with the injured person by the car owner or his insurance carrier, this law provides the hospital no redress. But it goes a long way toward taking the burden of caring for poor persons who have been injured in motor vehicle accidents off the shoulders of hospitals, where it does not belong, and placing it on the broad back of the whole group of motor vehicle owners.

Current Comment

WHAT PRICE EYES?

On other pages of this issue are reported six more cases of serious injury, one of them involving loss of sight, suffered by women who permitted beauty parlors to dye their eyelashes. In five of the six cases reported in this issue the serious effects were due to a product called "Lash-Lure." The Bureau of Investigation Department of THE JOURNAL published on September 23, this year, reports of seven additional cases, and the bureau now has in its files reports of four more. In other words, there have been sixteen cases of severe untoward effects reported following the use of a single product, Lash-Lure. This preparation is an aniline dye having for its base probably either paraphenylenediamine or paratoluylenediamine or some closely related substance. Every physician, and practically every responsible beauty parlor, knows the risk that is run in the application of dyes of the aniline type to the hair of the scalp. It has long been good beauty parlor practice to insist that persons who are to be subjected to

an aniline hair dye should be tested for sensitivity to that product. Because of the irritating effects of such dyes, there is no justification for the use of so dangerous a substance around the delicate tissues of the eye. As THE JOURNAL has pointed out repeatedly, cosmetics are under no national control. The National Food and Drugs Act defines a drug as a substance that is used for the prevention, mitigation or cure of disease, so that no matter how powerful, how poisonous or how deadly the drugs may be that enter into certain cosmetics, they are not drugs within the meaning of the act. As a result, the cosmetic industry is as free from legal restrictions of a national character in 1933 as the "patent medicine" industry was in 1905. Incidentally, it speaks well for the high character of the cosmetic industry generally in the United States that there is not more fraud connected with the business than there is. The Lash-Lure tragedies emphasize the need of some sort of national control over the sale of cosmetics.

THE EXCRETION OF SALICYLIC ACID

Although salicylic acid, employed in the form of salicylates, has long enjoyed an extensive use in clinical medicine its fate in the body has not been completely explained. Unlike some of the simpler organic acids, such as citric acid, malic acid and the fatty acids, salicylic acid is not burned up in the body. Much of the compound finds its way unchanged out of the organism by way of the kidneys. In part the ingested salicylic acid is subject to the apparent detoxicating mechanisms of the body, which are manifold.¹ Besides destruction by oxidation there may result several types of conjugation to render a somewhat toxic substance less harmful. Hydroxy compounds, either aliphatic or aromatic, are usually detoxicated by conjugation with sulphuric acid and excreted as ethereal sulphate, or, in case the supply of sulphuric acid is insufficient, glycuronic acid may take the place of the sulphate. Sherwin² has raised the question anew as to whether sulphuric acid conjugation or glycuronic acid conjugation enjoys predominance. Glutamine has been found as a detoxicating agent in man. Perhaps the most familiar mechanism is that by which the familiar amino acid glycine (glycocoll) is combined with benzoic acid to form the less offensive urinary constituent hippuric acid. Long ago it was reported that intake of salicylic acid is followed by the formation and excretion of a compound consisting of glycine and salicylic acid. It was named salicyluric acid in 1856 by Bertagnini³ because of its analogy to hippuric acid. Some investigators in more recent times have failed to find salicyluric acid and have therefore questioned its occurrence in human urine. According to the latest studies of Quick⁴ at the Fifth Avenue Hospital in New York, the human organism can synthesize salicyluric acid but the amount excreted is rather small. Quick believes that its importance has been overemphasized. He asserts that, contrary to the statement found in some

1 Sherwin C. P. *Physiol. Rev.* **2**: 238 (April) 1922.
2 Ambrose A. M. and Sherwin C. P. *Detoxication Mechanisms*
Ann. Rev. Biochem. **2**: 377 1933.
3 Bertagnini C. *Ann. Chem.* **97**: 248 1856.
4 Quick A. J. *J. Biol. Chem.* **101**: 475 (July) 1933.

of the textbooks on pharmacology, the excretion of salicylic acid is not rapid. For example, whereas the excretion of hippuric acid following an intake of 2 Gm of benzoic acid is complete in four hours, the elimination of salicylic acid is only 50 per cent complete in twenty-four hours. The rate of salicylic acid excretion is dependent on the concentration of the drug in the body. With increasing doses of salicylic acid, the excretion of the free acid becomes definitely greater, while the output of salicyluric acid is only slightly affected. The stimulatory effect of salicylic acid on uric acid excretion appears, according to Quick, to depend on a fixed concentration of the drug in the body. Below this crucial concentration no effect is observed. The action of salicylic acid on uric acid elimination is strikingly augmented by glycine or foods such as gelatin that are rich in glycine.

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks

The American Medical Association broadcasts on Tuesday and Thursday mornings from 8:55 to 9 o'clock, central standard time, over Station WBBM (770 kilocycles, or 389.4 meters).

The subjects for the week are as follows:

November 14 White Flour and Bleached Flour
November 16 Oyster Season Here Again

There is also a fifteen minute talk sponsored by the Association on Saturday morning from 9:45 to 10 o'clock over Station WBBM.

The subject for the week is as follows:

November 18 Itching

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALABAMA

University News—Dr. Luther L. Hill, Montgomery, gave the annual address commemorating the seventy-ninth birthday of William Crawford Gorgas before the Lafayette Guild Chapter of the Gorgas Medical Society, University of Alabama, October 3, his subject was 'Medical History.'

Society News—Dr. Charles O. King, Birmingham, addressed the Walker County Medical Society, September 8 on diagnosis of skin diseases of interest to the general practitioner.—Dr. Duane M. Carr, Ann Arbor, Mich., addressed physicians of the Tennessee Valley in Decatur, September 20, on 'Surgery of the Chest.'

ARKANSAS

New Government Hospital at Hot Springs—The new Army-Navy General Hospital, erected by the government in Hot Springs National Park at a cost of \$1,500,000, was opened to patients, September 20. The hospital said to be the tallest building in Arkansas will have a capacity of 412 beds as compared with 270 in the old hospital which it replaces. It is shaped with wings consisting of six floors and a heliotherapy deck while the central structure at the wing junction is twelve stories in front and six in the rear. On the first floor are the bath house with thirty immersion baths, three hydrotherapeutic towers and a hydrotherapeutic pool for paralytic patients, administrative offices, wards for women and children and isolation and detention wards. The second floor contains dental

offices with x-ray apparatus and laboratory, electrocardiograph, two large wards and twelve private and semiprivate wards. Facilities for the eye, ear, nose and throat and medical service with two typical wards and the main kitchen, food preparation and refrigeration rooms are on the third floor. Wards are on the fourth floor, and the genito-urinary service, hospital laboratory and two typical wards on the fifth floor. On the sixth floor, center, is the surgical service including orthopedic surgery and two large heliotherapy decks, while the seventh floor tower contains an x-ray clinic with two radiography rooms and one room each for fluoroscopy, roentgen therapy, film storage, dark room and viewing room. The physical therapy department is also on this floor. The eighth tower floor has private and semiprivate wards. Mineral water is supplied to drinking fountains on each floor of the building and to all bath equipment. The structure is of reinforced concrete.

New government hospital at Hot Springs

veneered with a light color face brick, trimmed with limestone and terra cotta, and embellished with ornamental aluminum and bronze. The Army-Navy General Hospital was established in 1883.

CALIFORNIA

Changes in Health Officers—Dr. Samuel G. Arnold has been named health officer of Long Beach, succeeding Dr. Grundy E. McDonald. The Kern County Health Department, of which Dr. Joseph K. Smith, Bakersfield, is the health officer, has taken over the health work of the city of Tehachapi. Dr. Rupert G. Doupe was formerly city health officer. Dr. Frank G. Crandall, district health officer of Whittier district, Los Angeles County, has been transferred to Santa Monica in a similar capacity. His new territory includes Santa Monica, Culver City, West Hollywood and the mountainous districts to the north.

Alumni Day—The University of California Medical School, San Francisco, will observe its semiannual alumni day, November 24. In addition to operative clinics, ward rounds and demonstrations the following papers will be presented:

Drs. James F. Rinehart and Stacy R. Vetter, 'Studies on the Etiology of Rheumatic Fever';
Dr. William I. Kerr, 'Etiology of the Common Cold';
Dr. William C. Deamer, 'Interesting Studies on Allergy';
Chauncey D. Leake, Ph.D., 'Development of Ideal Anesthesia';
Dr. John Homer Woolsey, 'What a Medical Center Can Mean to the Man in Practice.'

The annual Alpha Omega Alpha Lecture will also be given.

CONNECTICUT

Dr. McCollum to Lecture on Nutrition—Elmer A. McCollum, Ph.D., professor of biochemistry since 1917, Johns Hopkins University School of Hygiene and Public Health, Baltimore, will address a public meeting, November 16, in the Colonial Room of the Horace Bushnell Memorial, Hartford. The title of the lecture, offered under the auspices of the Connecticut Dairy and Food Council, will be 'Present Trends in Nutrition.'

GEORGIA

The Most Prevalent Diseases—Twenty-two per cent of the total number of cases in a group of twelve of the most prevalent diseases reported by physicians from their private patients were attributed to syphilis and gonorrhea in Georgia in 1932. There was a total of 23,347 cases of venereal disease when the number of clinic patients (13,848) was added to the number reported by physicians (9,499). Influenza led the list of the twelve most prevalent diseases in this group with a total of 15,085. Syphilis was second with 6,776. Others in order

were pneumonia, 4,252, malaria, 3,411, tuberculosis, 3,321, gonorrhea, 2,723, typhoid 1,799 diphtheria, 1,362 whooping cough, 1,085, measles, 1,075, pellagra, 986, and scarlet fever, 802. The total number of cases in this classification was 43,277.

District Meetings—The Eighth District Medical Society was addressed at Valdosta, October 10, among others, by Drs George E Atwood Jr Waycross on Laboratory and X-Ray Findings in Bronchopneumonia, Alton M Johnson, Valdosta, 'Vomiting in Infancy' George F Lubranks, Jr, Atlanta, proctologic problems, Charles H Richardson Jr Macon diagnosis and management of diseases of the biliary tract and Kenneth J McCullough Waycross management of pelvic inflammatory disease. At a recent meeting of the Seventh District Medical Society in Cartersville speakers included Drs John L Chandler Rome on Importance of Early and Regular Examinations of the Pregnant Woman Zebulon V Johnston Calhoun 'Diseases of the Uterus with Special Reference to Malignancies' William H Lewis Rome 'Significance of Pelvic Pain' and August F Routledge Rome 'Observations in the Treatment of Gonorrhea'. Speakers before the Ninth District Medical Society at a meeting near Jasper recently included Drs Grady N Coker, Canton and Daniel C Elkin Atlanta, on 'Rare Findings in the Surgical Abdomen' and 'Treatment of Aneurysm' respectively, Dr Clarence L Ayers, Toccoa, president-elect of the society also spoke.

ILLINOIS

Typhoid Outbreak at Bluffs—One death and ten cases of typhoid were recently reported in Bluffs a town of about 1,000 inhabitants. A preliminary investigation indicated that a milk supply was responsible but the observation of food and milk handlers is being maintained in an effort to determine definitely the source of the outbreak. Eight of the nine blood specimens examined proved positive for typhoid.

Society News—Dr John J McShane Springfield, spoke before the Christian County Medical Society in Taylorville, October 23, on epidemic encephalitis and other contagious diseases of the nervous system. Speakers before the Ogle County Medical Society at Rochelle October 26 included Drs Charles D Center, president-elect of the Illinois State Medical Society, and Thomas B Knox, sixth district counselor both of Quincy, on 'The Need of Cohesion' and 'Medical Care of the Unemployed', respectively. Dr Nathan S Davis III, Chicago, discussed 'Hypertension—Coronary Disease' before the Peoria City Medical Society November 7.

Chicago

Personal—Dr Elwood W Mason has been named instructor in medicine in the division of biological sciences University of Chicago. Dr Benjamin Goldberg associate professor in medicine, University of Illinois College of Medicine was given an honorary professorship in the National University of Mexico, October 30.

Program on Encephalitis—The recent outbreak of encephalitis in St Louis will be discussed at a meeting of the Chicago Medical Society November 22. The speakers will be Drs Hugh S Cumming, surgeon general, U S Public Health Service Washington D C Theodore C Hempelmann, associate professor of clinical pediatrics Washington University School of Medicine, St Louis, and Noel Paul Hudson, professor of hygiene and bacteriology University of Chicago.

Patients Wanted for Massive Radium Treatment of Tumors—The tumor clinic of Michael Reese Hospital is conducting a clinical investigation on massive radium therapy of a special group of neoplasms and will accept free of charge a limited group of indigent patients suffering from these conditions. The tumors under investigation are cancer of the tonsil, pharynx, larynx and prostate, also benign prostatic hypertrophy occurring in patients in whom operation is contraindicated. It is essential that these patients should not have received any previous radiation treatment. It is requested that the referring physician submit data concerning a case before sending the patient.

INDIANA

State Medical Election—Dr Walter J Leach, New Albany was named president-elect of the Indiana State Medical Association at its recent annual meeting in French Lick to take office in 1935. Dr Everett E Padgett Indianapolis will assume the presidency of the association in January 1934. Indianapolis was selected as the place for the next annual session.

Immunization Campaign—Two committees have been appointed to take charge of a campaign for immunization against diphtheria and smallpox, to be launched by the state advisory health council. Stanley Coulter, Sc D, Lafayette is chairman of one committee to prepare a bulletin on child nutrition and to encourage nutrition work in the public schools, and Dr Thurman B Rice, Indianapolis, chairman of the committee to plan the campaign.

KANSAS

Personal—Dr Frank Lightfoot has been appointed health officer of Great Bend, succeeding the late Dr Addison Kendall. Dr Schubert D Henry resigned as director of public health of Kansas City, effective August 1, and has been succeeded on a part time basis by Dr Henry W Kassel.

Society News—Dr William W Duke Kansas City, Mo, addressed the Shawnee County Medical Society in Topeka October 2, on 'The Dawn of a Specialty in Medicine Allergy and Physical Allergy'. Dr Rolla B Stafford, Salina, discussed medical practice in the Virgin Islands before the society September 5. Dr George B Morrison Wichita, addressed the Ford County Medical Society September 8, on transurethral prostatectomy. At a meeting of the Lyon County Medical Society, September 5, Dr John B Brickell Emporia, among others spoke on 'Surgical Treatment of Pulmonary Tuberculosis'. Dr John W Amesse Denver addressed the Sedgewick County Medical Society Wichita, October 6, on 'Newer Conceptions of Childhood Tuberculosis'. Drs Erastus F Edgerton and Howard C Curtis, both of Wichita spoke before the society, October 17, on 'Clinical and Surgical Aspects of Biliary Tract Disease and Mental Conditions Following Brain Injuries', respectively. Dr Lewis D Johnson Chanute discussed pyelitis before the Labette County Medical Society, September 27.

MASSACHUSETTS

Personal—Dr George H Bigelow, former state health commissioner, and his successor, Dr Henry D Chadwick were honored by the Massachusetts Tuberculosis League with a dinner in Boston October 26. Dr Bigelow is now director of the Massachusetts General Hospital succeeding Dr Frederic A Washburn. Dr Chadwick was formerly controller of the tuberculosis division of the Detroit Health Department. Dr Hans Zinsser professor of bacteriology and immunology Harvard University Medical School Boston was given an honorary degree by Lehigh University Bethlehem, Pa, during its celebration of Founders Day, October 4. Dr Zinsser delivered the principal address of the occasion.

Dr Mohr Gives Dunham Lectures—Dr Otto Louis Mohr professor of medicine Royal Frederiks University Oslo, Norway will deliver three lectures under the Edward A. Dunham Lectureship for the Promotion of the Medical Sciences on 'Genetics and Pathology' at Harvard Medical School. The individual titles of the lectures will be:

November 20. Basic Conceptions. Mechanism of Heredity and Sex Determination. Inheritance of Pathologic States in Man. Hereditary Factors in Pathology.

November 22. Origin of Injurious Hereditary Factors by Mutation. Their Action as Revealed by Illustrative Cases in Human Pathology. Lethal Factors. Pathology of Twins.

November 24. Interspecific Rays and Heredity. Alcohol and Heredity. The Tumor Problem. Inter-marriage and Crossing. Some Bearings of Genetics on Medical Practice.

Surgical Meeting—The annual meeting of the New England Surgical Society was held at Boston September 29-30. The following program was presented:

Dr Horace K Sowles. Carcinoma of the Small Intestine.
Dr Frank H Lahey. Operative Management of Cancer of the Rectum.
Drs Robert B Greenough Crantley W Taylor Charles E Dumas. Cancer of the Breast. End Results. Massachusetts General Hospital 1921-1922-1923.

Drs Taylor Channing C Simmons Richard H Wallace. Cancer of the Breast. End Results. Massachusetts General Hospital 1924-1925-1926.

Drs John Homans and George M Hass. Regional Ileitis. A Clinical Not a Pathological Entity.

Dr Ireland S McKinnick. Abdominal Symptoms With or Without Abdominal Lesions in Diabetic Acidosis.

Dr James Raglan Miller Hartford Conn. Spontaneous Rupture of the Stomach During Labor.

Dr Donald Munro. Diagnosis and Treatment of Acute Subdural Hematoma. A Report of Thirty Four Cases.

Dr Frederic Jay Cotton. Giant Cell Tumors of Bone.

Dr Ernest M Daland. A Study of 236 Compound Fractures Treated at the Massachusetts General Hospital.

Drs William J Mixer and Joseph Barr. Rupture of the Intervertebral Disk.

Dr Daniel C Patterson Bridgeport Conn. Appendices Epiploicae.

Dr Robert C Cochran. Suppurative Thyroiditis.

Dr Lyman Allen Burlington Vermont delivered his presidential address at the annual dinner at Harvard Medical School,

on "The Early Medical History of Vermont" Officers elected include Drs Frederick B Sweet, Springfield, president, Channing C Simmons, Boston, vice president, and John M Birnie, Springfield, secretary

MICHIGAN

Personal—Dr Henry S K Willis has been named superintendent of the William H Maybury Sanatorium at Northville, succeeding Dr Bruce H Douglas who has become controller of the tuberculosis division of the Detroit Health Department

Dr Armstrong Honored—Dr Oscar S Armstrong, Detroit was guest of honor at a luncheon October 17, given by the Business Pioneers Association of Detroit Dr Armstrong president of the Wayne County Medical Society in 1892-1893 is the oldest physician in point of continuous active practice in Detroit according to *Detroit Medical News*

Memorial Meeting to Dr Davidson—The surgical section of the Wayne County Medical Society held a memorial meeting in honor of the late Dr Edward C Davidson, October 23 Dr Roy D McClure opened the session with a talk on 'An Inspiration from His Life and Work' Other speakers were Drs Plinn F Morse on "The Pathology of Burns" and Grover C Penberthy, 'Surgical Management of Burns'

Society News—Speakers before the Berrien-Cass County Medical Society at Benton Harbor, October 23, included Drs Osborne A Brines and Ralph L Fisher Detroit on 'Role of Hemorrhage in Sudden Death' and 'Coronary Thrombosis' respectively—Dr William R Clinton, Detroit read a paper on 'Diagnosis and Treatment of Liver Abscesses' before the Jackson County Medical Society, October 3—The first meeting of the year of the Michigan Pathological Society at Eloise, October 14 was devoted to a discussion of ovarian tumor—Dr James Milton Robb Detroit, addressed the Monroe County Medical Society in Monroe, October 25 on medical economics—Dr William M Donald spoke on diabetes before the East Side Physicians' Association, October 26—At a meeting of the Detroit Oto Laryngological Society, October 18, Dr William Mithoefer Cincinnati, discussed 'Nasal Accessory Sinus Problems'

MINNESOTA

Mrs Melish Wilson Dies—Mrs Maude Melish Wilson for many years editor for the Mayo Clinic and author of a textbook on medical writing died at the Mayo Clinic, Monday, November 6 after a long illness

MISSOURI

Phonetic Laboratory—A phonetic clinical laboratory has been installed at the Central Institute for the Deaf St Louis where persons with defective speech and hearing may see a graph of the sound vibrations of their speech and compare it with pictures of normal vibrations The institute has an enrollment of sixty nine children in the grade school, sixty-seven children and adults in the speech correction department and thirty eight adults in the lip-reading classes

Society News—A symposium on deafness constituted the meeting of the St Louis Medical Society, October 24 with Dr Eugene T Senseney, Cordia C Bunch Ph D Dorothy Wolff Ph D and Dr Louis K Guggenheim as speakers The clinical manifestations of encephalitis were discussed by Drs Joseph F Bredeck Goronwy O Broun George Ives and James F McFadden before the society, October 17—A joint meeting of the Jackson and Wyandotte (Kan) county medical societies was addressed, November 14 by Dr Carl F Nelson, Lawrence, Kan, on 'Metabolism of Malignant Tumors'

NEW HAMPSHIRE

Personal—Dr John P Bowler Hanover, was elected president of the Association of Resident and Former Resident Physicians of the Mayo Clinic and Mayo Foundation at the annual meeting in Rochester, Minn October 7

NEW YORK

Veteran Practitioners Honored—The Orleans County Medical Association gave a dinner at Knowlesville recently in honor of four of its members who have practiced for more than fifty years Drs Fremont W Scott Medford Charles E Fairman Lyndonville Richard W Bamber Waterport and John E Sutton Albion Dr Fairman who has practiced sixty six years is said to be the oldest physician in point of service in the county Dr Scott was unable to attend the dinner on account of ill health

Society News—The program of the Nassau County Medical Society October 24 in Mineola, was devoted to discussion of peptic ulcer by Lester J Schultz, Ph D, New York, whose subject was "A Practical Intravenous Method for Treatment of Peptic Ulcer" and Drs Louis A Van Kleef, and Harold A Butman, Manhasset, "Peptic Ulcer—A New Intravenous Therapeutic Agent for Its Treatment"—The sixth district branch of the Medical Society of the State of New York held its annual meeting in Norwich, October 18 Guest speakers were Drs Floyd E Keene Philadelphia on "Radium Therapy in the Treatment of Uterine Myoma", Edward M Livingston, New York, 'Aids to Precision in Diagnosis A Practical Study of Abdominal Pain Rigidity and Tenderness', Frederic E Elliott Brooklyn, 'The New Economic Philosophy Applied to Medicine' and Arthur W Booth, Elmira, "Practical Points in Proctology"

New York City

Personal—Prof Otto H Warburg, director of the Kaiser Wilhelm Institute for Cell Physiology, Berlin-Dahlem and winner of the Nobel prize in medicine in 1931 delivered an address on physiology at Columbia University College of Physicians and Surgeons October 23—Dr Karl Landsteiner of Rockefeller Institute for Medical Research has been elected an honorary fellow of the Royal Society of Medicine, London

Cornerstone for Department of Health Building—A seven ton cornerstone for the new building of the departments of health, sanitation and hospitals was laid, October 30 Dr James Alexander Miller presided The laying of the cornerstone marked resumption of work on the building which was begun late in 1931 (*THE JOURNAL* Jan 2, 1932, p 56) It will be ten stories high and will cover the entire block bounded by Worth Centre, Lafayette and Leonard streets

NORTH DAKOTA

Society News—Dr John McEachern, Winnipeg, Manito, Canada addressed the Grand Forks District Medical Society, recently at Grafton, on cardiology—The North Dakota Academy of Ophthalmology and Otolaryngology held its fall meeting jointly with the South Dakota Academy at the Mayo Clinic, Rochester, Minn with addresses and demonstrations by members of the clinic staff as features of the meeting

OHIO

Personal—Francis L Landacre, Ph D, for many years chairman of the department of anatomy at Ohio State University College of Medicine, Columbus, died, August 23—Dr Henry J John, Cleveland has been named head of a newly created department of metabolic diseases at St Luke's Hospital, Cleveland newspapers report Fourteen rooms have been provided for the study of patients by the department which will for the present devote itself to diabetes and obesity

Institute on Vascular Disease—Drs Carl J Wiggers and Roy W Scott Cleveland and Geza de Takats Chicago presented a symposium on peripheral vascular disease at the meeting of the Cincinnati Academy of Medicine, November 6 Dr Wiggers discussed control of the circulation in the small vessels Dr Scott, clinical aspects due to changes in the blood vessels and Dr de Takats diagnosis and management Dr Walter M Simpson Dayton, led the discussion In connection with this meeting the Heart Council of Greater Cincinnati and the department of medicine University of Cincinnati College of Medicine joined the academy in presenting an institute on cardiovascular disease at the Cincinnati General Hospital during the day

PENNSYLVANIA

Hospital News—Dr Cyrus C Sturgis professor of internal medicine University of Michigan Medical School Ann Arbor will deliver an address at the Western Pennsylvania Hospital Pittsburgh November 14 on 'Anemia—Classification and Treatment' The occasion will inaugurate the celebration of an annual 'West Penn Day' to which the board of directors invites the medical profession

Assemblies for Practitioners—For the second year a series of special assemblies for practicing physicians will be held at George F Geisinger Memorial Hospital Danville during the winter The first meeting was held October 26 with Dr John A Kolmer, Philadelphia as guest lecturer Dr Kolmer presented two addresses on 'Present Status of Biologic Therapy in the Prophylaxis and Treatment of Diseases' and 'Methods of Evaluation, Compounds Employed in the Treatment of Syphilis and the Amount of Treatment to Be Given' respectively

Philadelphia

Division of Anesthesia—The medical board of the Philadelphia General Hospital has established a division of anesthesia in the department of surgery, with Dr Henry S. Ruth as chief. This move was made "to turn this art back to the medical profession" according to a statement issued by the board. Only physicians will be trained in the specialty.

Annual Dinner—The forty-seventh annual dinner of the Association of Ex-Resident and Resident Physicians of the Philadelphia General Hospital will be held Tuesday, December 5, at the Philadelphia Country Club Bala Pa. with Dr David Riesman as guest of honor. Ex-residents are requested to send their correct addresses to the secretary, Dr George Wilson, 133 South Thirty-Sixth Street, Philadelphia.

Society News—George W. Raiziss, Ph.D., among others addressed the College of Physicians of Philadelphia November 1, on "Experimental Chemotherapy and the Destruction of *Spirochaeta Pallida* in the Brain." At a meeting of the Obstetrical Society of Philadelphia, November 2, speakers were Drs Julia Faith Skinner Fetterman, on "Malignancy in Cervical Polyps," Robert A. Kimbrough, Jr., "Value of Hormonal Study in the Diagnosis of Chorionepithelioma," and Thaddeus L. Montgomery, "Premature Separation of the Placenta with Special Attention to the Placental Lesions." Drs Bernard P. Widmann and Herman W. Ostrum addressed the Philadelphia Roentgen Ray Society, November 2, on "Evaluation of the Roentgen Diagnosis of Aneurysms."

The Philadelphia County Medical Society observed Pennsylvania Health Day, November 8, with the following program of addresses: Drs James M. Anders, "Some Reasons Why the Layman Fails to Preserve His Health," Charles W. Burr, "Prevention of Mental Disease," and John A. Kolmer, "Infections of the Respiratory Tract with Special Reference to Prevention." Dr Howard W. Haggard, New Haven, Conn., was to address a special meeting October 30, according to the *Weekly Roster and Medical Digest* to present "an ethical practical plan, favorably considered by the Medical Economics Commission, to combat the quackery that is eating into your income and to increase the income of every ethical M.D." The scientific meeting of the society, October 14, was devoted to discussion of diseases of the colon, presented by Drs Martin E. Rehfuess, on functional disorders, Harry Shay and Jacob Gershon-Cohen, on organic colitides, and Damon B. Pfeiffer, on neoplasms.

UTAH

Society News—Drs Edward S. Pomeroy and Oza J. LaBarge presented papers before the Salt Lake County Medical Society, October 9, on "Relation of Prostatic Infection to Prostatic Hypertrophy" and "History of Medicine and the Allied Sciences Among the Saracens," respectively. Dr John Ruhrah, professor of pediatrics, University of Maryland School of Medicine, Baltimore, addressed the society at a special meeting, September 28, on infantile paralysis.

WISCONSIN

Personal—Dr Walter W. Peck, Darlington, recently celebrated the completion of his fiftieth year in the practice of medicine. Dr Robert S. Vivian has been appointed health officer of Beloit to succeed Dr Harry O. Delaney.

Society News—A symposium on x-ray films of the chest was presented at a combined meeting of the Outagamie and Waupaca county medical societies, October 17, by Drs Silvanus A. Morton and Arthur A. Pleyte, Milwaukee, Charles D. Boyd, Kaukauna, and Earle F. McGrath, Appleton. Dr Frank Gregory Connell, Oshkosh, addressed the Winnebago County Medical Society, Oshkosh, September 15, on peptic ulcer. Drs William S. Middleton, Madison, and Theodore L. Squier, Milwaukee, addressed the Medical Society of Milwaukee County, October 13, on "Manifestations and Recognition of Allergic Diseases" and "Treatment of Lobar Pneumonia," respectively, and Mr George G. Goetz, "Medical Relations with Insurance Companies." Drs Francis B. McMahon and Eben J. Carey addressed the Milwaukee Academy of Medicine, October 17, on "Carcinoma of the Lip" and "A Century of Progress in Medicine," respectively. Medical societies of Racine, Kenosha and Walworth counties held their annual joint meeting in Kenosha, October 4. Speakers were Drs Stanley I. Seeger, Milwaukee, on "Modern Treatment of Burns," Clifford G. Grulee, Chicago, "Interesting Conditions of the New-Born," and Harry E. Mock, Chicago, "Multiple Injuries with Skull Fractures." Following the dinner Mr J. George Crown-

hart, Madison, secretary of the Wisconsin State Medical Society, among others gave an address on "The Economic Status of Medicine in Wisconsin."

GENERAL

Radio Advisory Board to Byrd Expedition—A radio consulting medical advisory board to give the second antarctic expedition of Admiral Richard E. Byrd a consultation service in case of emergency has been formed. The board has representatives in the East and Middle West and on the Pacific Coast so that some member may be reached at any hour of day or night.

News of Epidemics—Thirty-two cases of smallpox were reported in Oshkosh, Wis., October 19. Schools and theaters of Windsor, Vt., were closed, October 16, after an outbreak of five cases of infantile paralysis with two deaths. The health officer of Okmulgee County, Okla., reported 113 cases of diphtheria in the county, October 18. Typhoid was also said to be prevalent.

Fifth Annual Goiter Award—The American Association for the Study of Goiter announces for the fifth year its offer of a prize of \$300 for the best essay based on original research work on any phase of goiter. Competing manuscripts must be in English and must be submitted to the corresponding secretary, Dr Julius R. Yung, 670 Cherry Street, Terre Haute, Ind., not later than April 1, 1934. The award will be made at the annual meeting of the association in Cleveland, June 7-9, 1934. It is hoped that the offer will stimulate research especially on the basic cause of goiter.

Society News—Dr Charles H. Mayo, Rochester, Minn., was chosen president elect of the Interstate Post Graduate Medical Association of North America at the annual meeting in Cleveland, October 16-21. Dr John M. T. Finney, Baltimore, became president. Dr Ross V. Patterson, Philadelphia, was elected president of the Association of American Medical Colleges at the annual meeting in Rochester and Minneapolis, Minn., October 30-November 1. Dr Charles W. Foynter, Omaha, was elected vice president and Dr Fred C. Zappfe, Chicago, reelected secretary. Nashville was selected as the place for the meeting in October, 1934.

Annual Tuberculosis Seal Sale—The National Tuberculosis Association announces its twenty-seventh annual sale of Christmas seals. Funds derived from the seal sale support the

activities of more than 2,000 state and local antituberculosis associations throughout the country. In spite of the past four years of depression the death rate from tuberculosis has continued to decline, but health officials are pointing out that this is probably the result of momentum gained in better times and that a rise may be expected when the full effects of reduced standards of

living are felt. Many sanatoriums have continued to operate through the loyalty of their staffs and low costs, but sooner or later many will have to close their doors, the association asserts, unless help is given.

Change in Status of Licensure—The Alabama State Board of Medical Examiners reports the following action:

Dr James T. Davis, Akron, license revoked for one year August 19 for the excessive use of alcohol coupled with morphine addiction.

Dr Julius G. Henry, Akron, license revoked for one year August 19 for the excessive use of alcohol.

The Georgia State Board of Medical Examiners reports the following action:

Dr Charles Verstandig, Atlanta, license revoked and declared void October 12. Dr Verstandig had been allowed to take the board examination under a misapprehension of facts since the board was under the impression that he was a graduate of a class A medical college.

The Massachusetts Board of Registration in Medicine reports the following action:

Dr Dwight T. Wilks, Boston, license suspended September 28 because of his conviction in court for conspiracy to perform an illegal operation. Dr Wilks is at present serving a six months sentence in Suffolk County House of Correction.

Annual Report of Rockefeller Foundation—After ten years of concentration on aid for building and endowment of certain medical schools, the Rockefeller Foundation has shifted its emphasis to support of specific research projects, according to the annual report for 1932. Of \$3,090,973 appropriated for the medical sciences during the year the largest amount, \$1,282,652, was given to McGill University, Montreal, for the establishment of a neurologic institute. Further attention was paid to the field of neurology by various small appropriations to institutions in Germany, Switzerland and London. Other

problems in medical research which received support during the year were studies of physiology of the acoustic nerve whooping cough and virus diseases, biologic research with radium and problems of sex. Funds were provided for 383 fellowships for workers in medical science. The foundation expended \$2,539,057.15 in 1932 for public health work, in which the principal aim was to correlate studies of a disease in its environment with investigations in the laboratory. An extensive program for control of yellow fever was carried on in cooperation with the government of Brazil, including support for a laboratory in Bahia, in addition to support of laboratory research at Lagos, Nigeria, and in New York. Studies were carried on in various parts of the world on malaria, hookworm, tuberculosis, yaws, undulant fever, the common cold, schistosomiasis and typhoid. In addition, the foundation contributed toward development of health services in forty three foreign countries, gave assistance to the central health administrations of eleven states and to local health work of 164 counties in twenty two states in the United States and, finally, provided 225 international fellowships in public health. The entire amount appropriated for the year was \$11,577,064 other fields covered being social and natural sciences and the humanities.

Southern Medical Association Meeting—The twenty-seventh annual meeting of the Southern Medical Association will be held in Richmond, Va., November 14-17, under the presidency of Dr. Irvin Abell, Louisville, Ky. General clinical sessions will be held the first two days at the Hotel John Marshall, with the following speakers, among others:

Dr. John O. McReynolds, Dallas, Texas, Role of the Crystalline Lens in the Function of Vision in Men and in the Lower Animals. Practical Consideration of Cataracts in the Human Subject.
Dr. George M. Piersol, Philadelphia, Clinical Value of Studies on Peripheral Circulation.
Dr. W. McKim Marriott, St. Louis, Some Therapeutic Procedures Based on Recent Advances in Biological Chemistry.
Dr. Dean Lewis, Baltimore, President, American Medical Association, Abdominal Lesions: Their Signs and Symptoms.
Dr. Oswald S. Lowsley, New York, New Developments in Kidney Surgery.
Dr. George T. Pack, New York, Treatment of Gastric Cancer by Surgery and Radiation Treatment.
Dr. Charles Mazer, Philadelphia, Diagnosis and Treatment of Functional Uterine Bleeding.
Dr. John deJ. Pemberton, Philadelphia, Rational Treatment of Hyperthyroidism.

Speakers who will address sectional meetings during the two following days include:

Dr. Charles F. McKhann Jr., Boston, Immunity in Infants to Infectious Disease.
Dr. Lawrence Brown, Saranac Lake, N. Y., Referred Abdominal Symptoms from Pulmonary Tuberculosis.
Dr. Hugh S. Cumming, surgeon general, U. S. Public Health Service, Washington, D. C., The Recent Outbreak of Encephalitis in St. Louis.
Dr. Charles A. McKendree, New York, Psychopathic Personality: Medical and Legal Aspects.
Dr. Byrl R. Kirklin, Rochester, Minn., Roentgenologic Features of Ulcerating Lesions of the Stomach and Their Differential Diagnosis.
Dr. Frederick A. Collier, Ann Arbor, Water Metabolism in the Surgical Patient.
Dr. Clay Ray Murray, New York, Recent Observations in European Orthopedic Clinics.
Dr. Logan Clendenen, Kansas City, Mo., The Stone Age of Surgery.
Dr. Edward H. Cary, Dallas, Texas, Ocular Tumors.
Dr. Jacob C. Geiger and Jacques P. Gray, San Francisco, Intravenous Use of Methylene Blue Solutions in the Treatment of Cyanide and Carbon Monoxide Poisoning.

Special clinics will be held by the following sections: dermatology, conducted by Dr. V. Pardo Castello, Havana, Cuba; bone and joint surgery, Dr. Robert W. Johnson, Baltimore; obstetrics and gynecology, Dr. Henricus J. Stander, New York; and Floyd E. Keene, Philadelphia, radiology, Dr. Byrl R. Kirklin, Rochester, Minn.; urology, Alfred I. Folsom, Dallas, Texas; and medicine, Drs. Oliver H. Perry, Pepper and Baldwin, H. E. W. Lucke, Philadelphia. In addition an allergy clinic and round table discussion has been arranged by Dr. Warren T. Vaughan, Richmond, who will hold clinics. Dr. George Piness, Los Angeles, will be the guest speaker on "Food Sensitivity: Its Status in Allergy." During the same week the National Malaria Committee, the southern branch of the American Public Health Association, the American Society of Tropical Medicine and the southern section of the Society for Experimental Biology and Medicine will hold their annual meetings in Richmond. A reception and ball in honor of the president will be held Wednesday evening at the Mo-que and there will be golf and trap shooting tournaments Thursday afternoon.

Deaths in Other Countries

Pierre Paul Emile Roux, director of the Pasteur Institute, Paris, renowned for research in collaboration with Pasteur and for his pioneer research on diphtheria, November 1, aged 89.
—Sir George Henry Makins, London, author and formerly President of the Royal College of Surgeons, November 2, aged 80.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Oct. 21, 1933

Facts About the Unfit

Lord Horder is the leading advocate in this country of birth control and the sterilization of the unfit. In an address in the graduate course at the Hampstead General Hospital he said that a national stock taking showed some unpalatable facts. In this country, one in 120 persons was feeble-minded, one in 200 was insane, and one in ten was too dull or too sickly to be absorbed into industry. The expense of educating and caring for these inefficient was enormous, but more serious was the fact that the future stock was being recruited from them. The aim of eugenics was to control the reproduction of unfit types and to encourage fertility in types above the average. But the eugenic movement sought to operate only by voluntary methods, doing nothing to infringe on the liberty of the individual. It advocated the voluntary sterilization under proper safeguards of all mental defectives, all mental convalescents and all who suffered from gross mental and physical defects that were proved to be transmissible. Compulsory sterilization though legal in some countries, was not advocated in this country.

In regard to birth control, he suggested that local authorities should be empowered to provide, under medical supervision, instruction in contraceptive methods for married women who asked for it on economic and eugenic grounds as well as on medical grounds on which alone instruction was now given. The science of heredity should be taught as part of the medical students' curriculum. Enormous opportunities for adding to the knowledge of genetics were lost by lack of training and therefore, lack of interest among physicians. There should be attached to the ministry of health a small group of medical men and women to whom vital statistics of life and death and disease should be readily available on the one hand, and contact with hospitals and general practitioners on the other.

Asthma Due to Deficiency of Epinephrine

The value of the injection of epinephrine in the treatment of asthma is well known but the theory, advanced at the Section of Therapeutics of the Royal Society of Medicine by Prof. J. H. Burn, that the attacks are due to deficiency of epinephrine in the system is new. He referred to the work of Loewi who suggested in 1921 that the autonomic nervous system acted by liberation of a chemical substance at its terminations. It was now accepted that the parasympathetic nerves liberated acetylcholine and it was widely believed that the sympathetic liberated epinephrine or an epinephrine-like substance. Dale and Dixon showed that tyramine acted like epinephrine but was less potent. But in a perfused organ the vasoconstrictor action of tyramine was lost (as well as that of ephedrine) although the constrictor action of epinephrine and the dilator action of histamine were well displayed. Further investigation showed that the site of action of tyramine and ephedrine differed from that of epinephrine for the action of the two former was lost in organs of which the sympathetic supply was degenerated while the action of epinephrine was retained. Hence epinephrine must act beyond the nerve endings while tyramine and ephedrine acted on these endings. But if the sympathetic nerve acted by liberation of epinephrine, a store of this substance must be already present at the nerve endings for release to enable tyramine or ephedrine to act. Professor Burn found also that in the presence of epinephrine both ephedrine and sympathetic stimulation produced vasodilator effects not otherwise seen. The conclusion was drawn that the response to sym-

thetic stimulation in the body depended on the amount of epinephrine in the circulation. This agreed with the observation of Graham that asthmatic patients who needed much epinephrine did not respond to ephedrine. Evidently their blood contained too little circulating epinephrine. Professor Burn considered such persons analogous to those deficient in thyroid secretion. Hence he suggested that those who had the least amount of circulating epinephrine would be predisposed to asthma. Attacks would occur because the bronchodilator nerves failed to act efficiently. They would be brought about whenever the bronchi were unduly constricted, by vagus impulses, by the reflex effect of nasal inflammation or by a chronic catarrhal state of the bronchi themselves. If the precursors of epinephrine could be identified, its formation might be increased in the body by their addition.

Food Poisoning from Pudding Made from Peas

A small outbreak of food poisoning from an unusual source has occurred in the St. Pancras district of London. It was traced to pudding bought in a shop. Ten persons who partook were taken ill; two (boys aged 11 and 13) died. The symptoms were diarrhea, vomiting, abdominal pain, passage of blood and mucus, cyanosis, tachycardia and high temperature. A high leukocytosis (up to 76,000) was observed. The pudding was made by boiling dried peas with sodium bicarbonate in an enamel sauce pan. The peas were then beaten up with salt in a glazed earthenware vessel. About six other persons bought the remainder of the supply but are not known to have suffered. Pudding made from the same supply of peas was sold on the preceding day without any ill effects being reported. Samples of the peas, bicarbonate and salt used were chemically analyzed without any impurity being found. In one case an organism thought to be *Flemer's bacillus* was isolated from the stools.

Panel Physicians in the Hands of Money Lenders

At a meeting of the National Association of Insurance Committees, it was stated that the cases in which young panel physicians assigned all their panel fees to money lenders were on the increase. In some cases they were the salaried servants of the money lenders and subject to a month's notice. The Lancashire Insurance Committee had on its books seventy-eight cases in which panel fees amounting to \$175,000 a year were assigned to money lenders, who were exercising an increasing influence on the administration of medical benefit though their only qualification was money. The young physician who had not the money to buy a practice went to an agency specializing in advancing on the security of practices. The first thing he had to do was to sign an undated form of resignation from the panel service and then a mortgage at the prodigious rate of 40 per cent. If he became soured and threw up the practice, the money lender would pocket the gains to date and look out for a fresh victim. He completed the form of resignation already in his hands and notified the insurance committee of the name of the successor. In one case the wife of a physician, herself also one, became a party to her husband's contract and covenanted to apply for admission to the panel list and have transferred to her her husband's patients, if called on to do so by the mortgagee. The association decided to refer the matter to the executive council to take whatever action was deemed necessary.

Automobile Accidents in London: Four Deaths Daily

Notwithstanding all that has been done to regulate automobile traffic—one-way streets, roundabouts and control of crossings by police as well as by automatic signals—a substantial increase in the number of accidents has been recorded in London in the last three months. The total number of fatal accidents for the three months ended September 30 was 381

compared with 304 for the corresponding period of last year. The number of persons killed exceeds an average of four a day. The number injured was 16,208, against 14,340 for last year. Private automobiles headed the list of vehicles involved, with 125 killed, compared with 87 last year. The other figures included: trade and commercial vehicles, 83 killed and 2,170 injured; against 66 killed and 1,795 injured last year; motor cycles, 80 killed and 3,420 injured, against 87 killed and 3,430 injured; omnibuses, 25 killed and 611 injured, against 20 killed and 527 injured; coaches, 16 killed and 162 injured; against 5 killed and 77 injured; cabs, 8 killed and 337 injured, against 6 killed and 297 injured last year; street cars, 6 killed and 329 injured; against 3 killed and 380 injured last year. Bicyclists were involved in accidents in which 33 persons were killed and 3,633 injured, compared with 25 killed and 3,015 injured last year. The increase in accidents is partly due to the constantly increasing number of automobiles on the streets, but increased speed seems to be more important and a demand has arisen for the reimposition of a speed limit which was abolished by the last road traffic act. Few pedestrians can cross a street in less than ten seconds while many modern streets require fifteen seconds. The pedestrians may look carefully to the right and left but do not appreciate that unless they run hard they may be struck by one of the cars in the distance or round the corner. On the other hand many drivers resent anything ahead which may check a smooth and rapid run and trust to the agility of pedestrians to avoid an accident.

Fatal Phrenic Avulsion

Phrenic avulsion is generally regarded as a trivial operation. But Drs. Cassidi and Lee of St. Thomas's Hospital have reported in the *British Medical Journal* a case in which it proved fatal. A lorry driver, aged 23, suffered from bronchiectasis following postoperative bronchopneumonia. He was expectorating a pint of fetid sputum daily and had lost 3 stone (19 Kg.) in weight. On admission to the hospital, Aug. 15, 1932, he weighed only 7 stone and 5 pounds (46.7 Kg.). The fingers were clubbed and the physical signs suggested gross bronchiectasis at the base of the right lung, with lesser involvement of the left base. By the injection of iodized oil intratracheally these findings were confirmed. He was treated by inhalations of creosote, postural drainage and bronchoscopic lavage but steadily deteriorated. Phrenic avulsion was attempted under local anesthesia, Jan. 16, 1933, the operating table being tilted so as to elevate the head and chest. The nerve was exposed in the neck and clamped, whereon the patient hiccuped once and became acutely dyspneic. After an abortive attempt to cough he lost consciousness. A tracheal catheter was passed and a considerable quantity of pus aspirated. Oxygen was then blown in by way of the trachea and he slowly improved. The incision was rapidly closed and no attempt made to proceed with the operation. He was sent to the ward, where he again became acutely dyspneic and died. The necropsy showed complete collapse of the lower half of the right lung. The trachea and main bronchi contained much pus. Gross bronchiectasis involved the right lower lobe with cavities of the size of a walnut. Bronchiectasis in much less degree involved the rest of both lungs. Death was attributed to asphyxia consequent on sudden flooding of the whole bronchial tree by pus squeezed out of the cavities in the right base when the right dome of the diaphragm made its rapid ascent. The authors suggest that preliminary postural drainage or bronchoscopic lavage would have saved the patient.

Death of Sir Arthur Mayo Robson

The death of Sir Arthur Mayo Robson, at the age of 80, removes a great pioneer of abdominal surgery. A Yorkshire man by birth, he was educated at the Leeds School of Medicine,

where he distinguished himself by obtaining every prize open to a student, though he had at the same time to work as assistant to a local physician. In 1876 he was appointed lecturer on anatomy in the school, and in 1884 he became surgeon to the Leeds General Infirmary. Later he was appointed lecturer in pathology in the school and professor of surgery in the Yorkshire College. In 1902 he moved to London. His most important pioneer work was done on the treatment of gallstones and diseases of the bladder, on which he was the leading authority of his day. He wrote on these subjects in Allbutt's System of Medicine and in Keen's System of Surgery. In a tribute to him, Lord Moynihan, who was his house surgeon, says "His capacity for seizing upon relevant features in a new problem, of capturing the essential principle and neglecting specious nonessentials seemed like wizardry." At one period he was the greatest surgeon in Europe. Though his chief work was abdominal, he distinguished himself in the whole field of surgery. He was the first in this country to undertake nerve grafting. He quickly followed Allingham in removing torn semilunar cartilages. He was one of the first to excise spina bifida. His fame as an operator was so great that surgeons came from all over Europe to see him at work. He was president of the Surgical Section of the International Medical Congress in 1900 and 1906 and of the British Gynaecological Society. At the outbreak of the Great War he had retired from practice, but he at once went with a field hospital to France and by invitation of the French authorities organized a complete hospital for the French army. For his services he was appointed to the Legion of Honor. He also served in Egypt and Gallipoli.

Dr Banting Honored

Dr F. G. Banting, professor of medical research in Toronto University and the discoverer of insulin, was admitted an honorary fellow of the Royal College of Surgeons. He was already a member of the college. He was welcomed by the president, Sir Holburt Waring, and signed the roll in the presence of the council. It is three years since Dr Banting was nominated for the fellowship, but this was the first opportunity to confer it on him. He was born in 1891.

Important Changes in the Medical Curriculum

The superior council of public instruction has made two important changes in the medical curriculum. The first point concerns a modification in the program of premedical studies that was formerly pursued in the schools of medicine. The professors of medicine complained then that this program was too theoretical and that it amounted practically to the loss of a year's time, for the student should be brought as soon as possible, in contact with the anatomic institute and the hospital wards. Under the influence of these arguments a preliminary certificate for medical students was granted after a year's study in a faculté des sciences. It is now recognized that this was a mistake. The instruction of the professors in the facultés des sciences proved to be much more theoretical than in the facultés de médecine, and quite disconnected from any applications to medical practice. Furthermore it was necessary to retain in the facultés de médecine the chairs of instruction in medical physics, biologic chemistry, parasitology and materia medica and pharmacology, with the result that the students go twice over the same material. The facultés de médecine would have liked to have the preliminary certificate abolished and replaced by a year of supplementary studies added before the terminal thesis in order to increase the students' clinical experience.

The facultés des sciences in the discussion before the superior council refused to dismiss the professors in charge of the studies in question. However, the facultés de médecine gained their main contention, and the creation of a supplementary year was granted. Hence, beginning Oct 1, 1934, students of medicine must complete six years of medical study which is going to add a considerable amount to the total expense of a medical education. There will be many protests. The preliminary medical course, it appears, will be modified, taking on a more directly biologic character. This change seems hardly justified since the sciences studied in the facultés des sciences will be repeated in the faculté de médecine during the third year. The sixth supplementary year has more to justify it. The medical students, French and foreign, have become so numerous, in spite of the unfavorable future outlook for the medical profession, that only the students who secure, through a competitive examination, posts as interns or externs can take up the practice of medicine with much hope of a reasonable compensation. The others are only auditors of the professor's lecture in the hospital wards, far from the patient's bedside, and are never permitted to make an examination of the patient on admission, to apply a dressing, to give immediate treatment of a dislocation or a fracture, much less to perform a surgical operation of any kind, all this work being reserved for the interns and externs. Henceforth, students who have hitherto been at a great disadvantage will, for one year, live the same life as the interns and externs and will perform important services both night and day under the same conditions that obtain for real professional practice. When the hospitals located in the university cities become too crowded, which is the case in Paris and Lyons, students will be permitted to serve as assistants in hospitals located in the provinces, where assistants are often much needed. The proposed reform will contribute toward raising the standard of general practitioners. Another regulation introduced by the superior council reinforces the rigorous character of the various examinations and provides for the definitive elimination of a student after a certain number of failures. The latter reform has received the strong approval of the Confederation des syndicats médicaux, as likely to aid in doing away with the surplus of physicians, and has appeared preferable to the limitation of the number of students to be admitted by the facultés de médecine. The latter method did not appear feasible because of the wide variations in attendance at the various institutions.

The New Neuropsychiatric Clinic

The Clinique de neuro psychiatrie infantile, created at the Faculté de médecine de Paris, is an innovation. The suggestion for the creation of the clinic emanated from a Paris attorney, Mr. Rollet, who was animated by a lofty spirit of charity, developed by his contacts with the movement in aid of delinquent children. With perseverance, he has succeeded in creating within the French system of judicial organization, special courts for the trial of children charged with various misdemeanors who heretofore had been tried by the ordinary courts along with adult criminals. The judge had either to commit the child to a house of correction—a sort of prison school and workshop combined—where his complete corruption was almost a certainty, or to return him to his parents, that is to an environment in which the absence of supervision had been the cause of his downfall. The children brought before the juvenile court are now subjected to an examination by medical specialists in the children's psychiatric clinic before any further action is taken. The new clinic created meets this need and is open at the same time as a public dispensary to the parents who of their own accord take their children there before the police has had occasion to arrest them for some misdemeanor. The clinic serving also as a center of study and instruction in

visited frequently not only by physicians and legislators but also by psychologists eager to study various phases of mental development in man. The well known writer of novels Paul Bourget, who is 80 years of age, is one of the most frequent visitors at the dispensary. Of the 665 children examined during the six months just passed, 35 were sent to psychopathic hospitals. This group was composed of psychopathic patients, idiots or imbeciles, children with a greatly disturbed equilibrium, epileptic patients, patients who have only partially recovered from encephalitis, inadapted pervers, and adolescents with dementia praecox. Fifty nine children were placed in institutions of reform, 277 were turned over to children's hospitals for treatment, 237 were entrusted to an *auteur de patronage* or home-finding society which places the children in the rural districts in the homes of farmers to learn farming, where they remain under the periodic control of the society. Thirty-two were placed in special homes for girls while twenty-four remained under observation.

Vaccination Against Yellow Fever

Yellow fever continues to be widely prevalent in the Senegal although it is decreasing. The authorities have become resigned to the belief that the disease can be eradicated only through the general application of vaccination. The Institut Pasteur de Paris has therefore organized a public vaccination service for persons about to go to the Senegal which service is under the direction of A. Pettit and C. Stepanopoulo who have made special studies on yellow fever. Since 1926, they have made from inoculated monkeys an excellent immunizing vaccine. They can no longer procure a sufficient number of monkeys, however, since the price of them has risen. They employ, therefore, concurrently the procedure of Drs. Sawyer, Kitchen and Lloyd of the Rockefeller Foundation, which comprises a virus and an immunizing serum the latter being derived from convalescent subjects. They have, however, modified the procedure by substituting immunized horse serum for the serum of convalescents since the horse serum is easier to procure and is more active. Mr. Stepanopoulo has vaccinated himself in this manner. Mr. Pettit is already immunized, having contracted yellow fever during his mission in the Senegal, about the time that Noguchi's death occurred.

BERLIN

Sept. 25, 1933

Public Health Department Dissolved

In connection with the administration of the reich by the national-socialist party, the department of public health has been dissolved and in its stead an expert council on public health created. Dr. Wagner, the leader of the German medical profession, has been chosen to organize the new council and to serve as its director. This council will handle all questions having to do with the preservation of the health of the German people, particularly questions pertaining to demographic science, hereditary biology, race hygiene, social hygiene and popular enlightenment on health problems, including questions that concern exponents of nature cures and various therapeutic cults. All party headquarters must submit to this council all questions that concern the fields taken over by the council must present all measures before they are carried out and must turn over for approval all reports to the authorities before they are submitted. In all matters that come under its jurisdiction, the council will deal with the reich, the *länder* and the communes and likewise with bodies established for the interpretation of public law, and is entitled to present inquiries, protests and petitions to these centers. The governmental authorities of the reich and the *länder* are requested when taking up matters

coming under the jurisdiction of the council, to get in touch with that body before reaching conclusions, and to issue similar instructions to subordinates and to legal bodies.

The Haff Disease

In previous letters the peculiar manifestations of disease occurring in the vicinity of the Haff, an arm of the sea, in East Prussia, have been discussed. At that time it was considered that acids combined with a resinous base were the cause of the disease, which originated chiefly in fishermen. The whole situation is not yet clarified. However, a survey by the Würzburg pharmacologist Professor Flury, in the *Klinische Wochenschrift* deserves attention. The assumption that the disease is due to arsenic poisoning which has long been the official conception is untenable, nor has adequate proof been furnished for the assumption that resinous acids play a causal role. The poor results following the introduction of preventive measures and the interruption in the development of new cases, would indicate that the origin of the disorder is not to be found in the municipal or industrial waste waters. It appears more than likely that the Haff itself contains the source of the poison. Through the disintegration of countless animal and vegetable organisms and particularly those of a microscopic nature vast quantities of poisons may be formed in the waters of the Haff. They may be of an exogenous nature—hemolytic, for instance—muscle and nerve poisons of the spirotoxin or the curare group, which are traceable to plankton accumulating in the mud and thence ingested by fish. On the other hand endogenous factors arising in the organism of human beings or of fish cannot be excluded. The fish diet of the population must have a connection with the disorder. In any event, it is an exaggeration to state, as the press did recently, that the Haff disease mystery has been cleared up.

Exaggerated Advertising of "Patent Medicines" Prohibited

For many years the exaggerated claims made in the advertising of "patent medicines" to the public have been a constant source of complaint. The *Nachrichtenblatt des Nationalverbandes der Deutschen Heilmittelindustrie* has published the new regulations to be observed in the advertising of medicines as set up by the 'Begutachtungs- und Beratungsstelle für Werbungsfragen'. The following excerpts deal with essential points. The advertising to the public of medicines alleged to be effective in grave diseases and advertising encouraging self-treatment of cancer, diphtheria, lupus, pulmonary tuberculosis, epilepsy, arteriosclerosis and the like, must be absolutely stopped. Testimonials of laymen prove in such cases absolutely nothing. Every manufacturer must therefore make a thorough investigation in order to ascertain whether he can furnish unquestionable scientific proof that the preparation or the apparatus will actually accomplish what he promises, the manufacturer who exceeds such limitations is subject to a penalty. The health authorities consider such assertions as "The remedy helps at once or never fails to help" as unprovable. The manufacturer may state 'The remedy has helped' if on demand he can furnish documentary proof based on scientific tests. Other exaggerations are warned against, for example, the use of the term 'preeminent' in referring to the remedy or the term 'glorious' in referring to the results. That manufacturers must avoid all misleading superlatives goes without saying. Advertisements in which an individual is put forward in the role of a 'grateful patient' to inform persons interested how he was cured of a grave disease are prohibited, they are calculated to deceive the public, since in reality the manufacturer is the one who inserts and pays for the advertisement. Testimonials and letters of thanks supplied by laymen have

little weight in proving the value of medicines. Such testimonials must not contain untrue statements or exaggerations calculated to deceive. Prophylactic remedies may not in this manner be put forward as medicines. The following explanation is given: "If the pharmaceutical industry does not wish to incur the danger of having the use of testimonials in advertisements entirely prohibited, it must of its own accord impose certain restrictions on itself. It is absolutely inadmissible to select from available testimonials precisely those for publication that announce a cure in a particularly severe case. Under no circumstances may the impression be given that results that were possibly secured under especially favorable circumstances are always attainable or to be expected with certainty." When the statements of physicians are used, names and places must without fail be given in unabbreviated form. The use of any official titles that might give a false impression is strictly forbidden. Writers of advertising copy who, for a remuneration, furnish favorable testimonials may possibly have their names published in connection with their offense. Guaranties of a cure are absolutely prohibited, likewise promises to return the sum paid for the remedy in case it does not prove effective. In stating the effects of the remedy, every advertisement must make it clear how the remedy acts in the disease in question and to what extent it can consequently influence the course of the disease. A statement that the remedy is of aid in a long list of diseases is deceptive.

JAPAN

(From Our Regular Correspondent)

Aug 28, 1933

Outbreak of Epidemic Encephalitis

Since the epidemic of 1924, encephalitis has appeared sporadically. Since last June, however, it has again been increasing in the central parts of Japan, and suddenly it broke out in the Rikyu Islands in the east China Sea near Formosa. From June to the end of July, sixty-eight cases were found, with twenty-five deaths. Of 298 patients in other districts 161 died. The total deaths were 220 out of 427 cases throughout the country. The Japan Science Promotion Association has formed a commission to study the cause of the epidemic. Professor Inada of the Tokyo Imperial University medical department has been appointed chairman. The commission is divided into eleven sections, each section having as its leader a well known specialist. Two groups have already been sent to places where the disease is raging. As this epidemic threatens to spread all over the country, the police and physicians are cooperating to prevent a general outbreak.

Study of Woman's Work on Farms

The Kurashiki Scientific Research Institute for Labor which was established by a millionaire and is the only institute of the kind in this country, has recently opened a department to study agricultural labor. Dr. Teruoka, chief of the institute, says: "About half of the people of Japan follow agriculture as their means of living. A characteristic of Japanese agriculture is that the work is done by family cooperation. In a farm house the master works eleven hours and forty-five minutes a day on an average, while the mistress works eight hours and fifty-nine minutes a day, besides doing domestic work for about four hours a day, so her work hours number thirteen. Her part in farming operations as a laborer as well as a mother is most important. Of late agriculture has inclined to man-sided operations, only to add more to her labor. What kind of culture and education has been given the woman who is to play such a valuable part in this great industry? Only a conservative traditional training has been given her, disregarding the strides made in all other business in recent years."

The institute is going to deal with material and information to be originated by itself to aid women to adjust themselves to modern ways. In order to obtain the best results of study, thorough and deliberate researches of a small number would be preferred to a great number of hurried investigations. The families to be studied with regard to their health and labor have been selected. They all belong to the middle class with a yearly income of about 1,000 yen and live on one hectare or so of land.

Roentgen Treatment of Filariasis

Filariasis, which is mainly found in the southern Loochoo Islands and in some districts in Japan proper, has long been considered incurable. After years of research Dr. Yamaguchi of the Nagoya Medical College has succeeded in treating the disease with the help of the x-rays. The only treatment heretofore applied was by means of drugs. Dr. Yamaguchi has shown that from eleven to twenty-two treatments with the x-rays all over the body will destroy the generative cells of the filaria and stop their reproduction, at the same time reducing the induration of the lymphatic vessels. He thus successfully treated all patients sent in. His success is considered here almost miraculous.

Society News

The Japan Physiologic Society held its twelfth general meeting at Kanazawa in July under the chairmanship of Dr. Ueno. Papers were read on noise, diet, nutrition, the relation between humidity and perspiration, and the theory of nerve conduction. There were many papers on the study of the heart. The meeting lasted three days, and 201 papers were read.

The Friendship Between Billroth and Brahms

Dr. Janos Bokay, retired professor of pediatrics at the University of Budapest and founder of the Medical Philharmonic Society, recently addressed the medical society on the friendship between Johannes Brahms and Billroth. It began when the latter taught surgery in Zurich (1860-1866). Brahms, yet a youth, was nearing the peak of his development as a composer of music. The Billroth-Brahms friendship lasted for almost three decades until the death of Billroth in 1894. There was scarcely four years' difference between their ages. Billroth was born in 1829, Brahms in 1833.

Billroth had a craving for music and he played well. In early youth he prepared for a musical career and from the great number of letters collected during the time of his professorship it is evident that his love for music lasted until his death. While in Zurich he wrote musical criticisms for the foremost newspaper and a large number of eminent musicians were his close friends. The Allgemeine Musik Gesellschaft of Zurich had a high opinion of Billroth's musical views, which were often asked for.

Billroth was a gifted pianist and he learned the viola from Eschmann. He played the viola in company with professional musicians. He cultivated chamber music also in Vienna and often played at his home in Alser Strasse with his friends. In a manuscript of 250 pages found in his desk he had written, two days prior to his death, the following words: "This manuscript should be handed to my dear friend Hanslick, who is to decide about it according to his judgment. The manuscript appeared in book form in 1898 with the title *Wer ist musikalisch?* with a foreword by Hanslick. Billroth composed several songs, which however remained only in manuscript with the exception of one *Todessehnsucht* which was published after his death as a supplement to *Praxis von Theodor Billroth*."

According to Tibor Gyori, teacher of medical history at Budapest, Billroth composed also a one act opera, which was performed at his home before an audience of distinguished friends. Of the 442 letters collected and published in 1895 in Hanover, Billroth wrote thirty-five to Brahms, twenty-nine to Hanslick and the rest to prominent medical men.

In 1867 Billroth occupied a professorial chair in Vienna, where Brahms had already moved. June 2, 1867, he wrote to Lübke: "I am every day in the company of Brahms." December 24, he wrote: "Brahms is ever more and more amiable." In 1867, Billroth resolved with Brahms to spend some weeks in Italy. About this excursion Brahms recorded the following episode: "When they were on a boat going from Naples to Sicily, a woman passenger was suddenly beset with labor pains. The captain knowing that Billroth was on the boat, asked him to give medical attendance to the woman. Billroth wavered a bit, saying he had no obstetric experience, but he proved to be an excellent obstetrician in this case and he himself was amazed at his success."

Billroth became in Vienna the subject of great admiration. The busy professor, however, could spare time every evening to meet his musical friends. In 1877 he wrote to Brahms:

"My relation with the goddess *Musica* has slackened lately, owing to my many official and medical activities. Now that I am on a holiday I start a new relation with her. I brought with me my upright piano, all your songs and other notes, and I greet you through the mountains." In 1885 he wrote: "I am dissatisfied with myself that I pay less and less attention toward the Muses. Of course, they remain ever young while I. I am sorry to say, get older from year to year." First he still used his piano as shown in a letter written to Hanslick in which he informed him with great pleasure: "Tonight we made with Fraulein Erna von Bamberger a four hand revel within two hours we ran through Tschirnikowski's two big orchestral scores and Tuchs's *Glimmer*."

Billroth's devotion to Brahms increased. When on Nov. 6, 1890 he had Brahms's new G flat quintet with two violas he went to his desk at 1 o'clock in the morning and wrote: "The greater part of the time of your budding I lived with you and I often meditated about what is real happiness. Well, tonight, listening to your music I was happy. This stands quite clear before me." Brahms met his musical friends in the *Igel*, a restaurant in Vienna. In his advanced age he willingly accepted invitations to dinners. He enjoyed good foods, particularly if good wines were served. Ehrbar, the Vienna piano manufacturer celebrated every birthday of Brahms, May 7, by arranging an asparagus breakfast. Among the guests were all the most intimate friends of the master, and Billroth, Hanslick and Goldmark were never missing. The breakfast was served at noon. Although the piece de resistance was the asparagus, which was served abundantly, there was plenty of ostrich and caviar and *Veuve Chiquot* champagne.

In 1892 Billroth felt the onset of symptoms of arteriosclerosis. He wrote to Brahms: "For three days I have again felt worse and until the end of the week I have to dose myself with digitalis." Yet his love of music held fast and in the same letter he said: "Yet I occupied myself with your music more than ever, all your four hand notes were with me and I played them in company with Dr. *Fleischl of Rome*." The disease, however, disturbed the strong body of the great genius more and more and Billroth's capacity began to drop in every direction. Four weeks prior to his death Billroth wrote to Professor Czerny, operative surgeon of the Heidelberg university: "If I live I shall open the new clinic in the autumn of 1895 and then in the course of the next year I shall retire. But with my ever increasing heart weakness I doubt whether I shall live to that time. I am resigned to anything. I am prepared for

the road." Jan. 12, 1894, he wrote to Brahms (the four hundred and forty-first letter): "In spite of the admirable weather I feel unwell. I cannot sleep and I have difficulty in breathing. Besides my broodings I have no recreations." This was the last letter addressed to Brahms and in spite of his condition he contemplated at length the national German dance music and German folk songs.

Billroth closed his eyes forever, February 8. In 1880, he wrote to Brahms on the occasion of the burial of a friend: "I should not like to cause obstruction in bustling *Alser Street*. I wish to be carried into the Central cemetery without music, in a simple way. There some music, a few words at the grave by one of my friends or pupils, again some music." However Billroth's burial took other course. A huge mass of people blockaded the traffic the entire way. Brahms wrote to his friend Widmann about the burial: "In the innumerable mass of men there was not one curious or indifferent face only sympathy and love." Brahms was much affected by Billroth's death and three years afterward he also died. March 7, 1897, Brahms appeared at a philharmonic concert in Vienna. The first number of the program was his fourth symphony which was a great success. Brahms, who had been sitting in the background came forward to receive an ovation. As Hanslick wrote: "Devotion and sympathy suffused the whole audience a clear presentiment of the fact that in this hall the Master was being greeted for the last time." From this time on Brahms's condition became worse from day to day and on April 3 he died.

He was buried in the Vienna Central Cemetery in the vicinity of Schubert's grave close to the mound of Beethoven. One of his biographers remarked: "His soul flew into the sunlit home whereto prior to him, in quick succession, went Hans von Bulow, Teodor Billroth and Klara Schumann, three people who stood nearest to his heart."

Marriages

ROBERT LANE WARE, A Surg. Lieut. (j g) U. S. Navy, to Miss Mary Fairfax McCallie at Chattanooga, Tenn., in August.

RAYMOND HARRISON RIGDON, Durham, N. C., to Miss Mary Anita Stigers of Atlanta, Ga., October 2.

FRED ARNOLD KENNEDY, Sacaton, Ariz., to Miss Lilian Emeline Ball of Cohasset, Mass., October 17.

ERNEST WILLIE GRUMBLES, Cristobal, C. Z., to Miss Ella Pattee of Little Rock, Ark., September 15.

ROBERT EDWARD LEE GUNNING, Galesburg, Ill., to Miss Jean Zearing of Princeton, October 7.

SAMUEL RALPH TERHUNE to Miss Pauline Carolyn Veitch, both of Birmingham, Ala., October 14.

JAMES CARLISLE MOORE, JR., Marion, S. C., to Miss Evelyn Brabham at Bamberg, August 5.

WAITER PERCIVAL RHYNE, Albany, Ga., to Miss Myrtis York of Clarksville, October 4.

WILBUR P. BAILEY, Philadelphia, to Miss Margaret Robinson of Paoli, Pa., October 28.

FLETCHER ADRIAN SMITH, Elberton, Ga., to Miss Nell Wilson of Vidalia, October 1.

RAY WOZESKE KING to Miss Mary Rose Sherburne, both of Peoria, Ill., August 24.

JOHN COUDON STAGEMAN, Detroit, to Miss Leola Francis at Waterford, August 19.

HERMAN C. CLAYTON, Sidney, Ohio, to Miss Gladys Pardee, in Cincinnati, August 6.

ROBERT ALEXANDER ROSS, Durham, N. C., to Miss Rosaline Walter, October 4.

CHARLES FRANKLIN MOHR, Baltimore, to Miss Mary Caroline Hood, July 1.

Deaths

John Speese * Philadelphia, University of Pennsylvania School of Medicine, Philadelphia, 1902, associate professor of surgery, University of Pennsylvania Graduate School of Medicine formerly assistant professor of surgical pathology at his alma mater, member of the American Surgical Association, fellow of the American College of Surgeons, aged 53, on the staffs of the Children's Hospital and the Presbyterian Hospital where he died, October 15, of coronary occlusion

John Dean Elliott, Philadelphia, Hahnemann Medical College and Hospital of Philadelphia, 1901, clinical professor of surgery at his alma mater, fellow of the American College of Surgeons, served during the World War surgeon to the Hahnemann and Woman's Southern Homeopathic hospitals and the Abington Memorial (Pa.) Hospital, aged 57, died October 8

Andrew Curtin Santee, Middletown, N. Y., Jefferson Medical College of Philadelphia, 1886, member of the Medical Society of the State of New York, member of the board of education and health officer of the towns of Wallkill and Wawayanda, on the staff of the Horton Memorial Hospital, aged 69, died, October 16, of carcinoma of the prostate

Oliver Rowland Blanchard * Jersey City, N. J., University of the City of New York Medical Department, 1891, past president of the board of education, one of the founders and president of the Fairmount Surgical Sanatorium, on the staffs of the Jersey City and St. Francis' hospitals, aged 75, died, October 14, of heart disease.

William Benjamin Jackson, Cambridge, Mass., Harvard University Medical School, Boston, 1880, member of the Massachusetts Medical Society, formerly member of the board of health of Lowell at one time on the staffs of the Lowell Corporation Hospital and the Lowell General Hospital, Lowell, Mass., aged 80, died, October 6

John Harvey Jewett, Canandaigua, N. Y., College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1879, member of the Medical Society of the State of New York, on the staff of the Thompson Memorial Hospital, aged 79, died, October 14, of heart disease

Andrew Victor Sykes, Winnipeg, Manit., Canada University of Toronto Faculty of Medicine, 1924, served during the World War, on the staffs of the Children's Hospital of Winnipeg and St. Boniface (Manit.) Hospital, aged 36, was killed, August 13, in an automobile accident

Joseph Aloysius Mehan * Lowell, Mass., Tufts College Medical School, Boston, 1906, member of the New England Roentgen Ray Society and the Radiological Society of North America on the staff of St. John's Hospital, aged 56 died October 12, of hypernephroma

Joseph C. Brookhart, Oak Forest, Ill., St. Louis College of Physicians and Surgeons, 1903, member of the Illinois State Medical Society, on the staff of the Cook County Tuberculosis Hospital, aged 53, died suddenly, October 17, of heart disease.

Albert Okerstrom, Berkeley, Calif., College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois 1905 also a minister, aged 62, died September 20, in the University of California Hospital, San Francisco

George Hutchins McNemer * Cairo, Ill., University of Louisville (Ky.) School of Medicine 1889 past president of the Alexander County Medical Society formerly on the staff of St. Mary's Hospital, aged 67 died suddenly October 18

Henry Berrien Shaw, New York, College of Physicians and Surgeons Medical Department of Columbia College New York, 1877, member of the Medical Society of the State of New York, aged 82, died, October 10, of chronic endarteritis

Rudolph A. Rulmann * Minster, Ohio Medical College of Ohio Cincinnati 1881 past president of the Auglaize County Medical Society member of the county board of health aged 73 died October 7, in St. Rita's Hospital Lima of uremia

John Bernard Stackable Fort Worth, Texas, Fordham University School of Medicine New York 1912 member of the Medical Association of Texas served during the World War aged 59 died September 22 of chronic polyarthritis

James Walter Rendleman * East St. Louis, Ill., Jefferson Medical College of Philadelphia 1894 past president of St. Clair County Medical Society on the staff of St. Mary's Hospital, aged 65 died October 13 of heart disease

Lewis Heisler Ball, Marshallton, Del., University of Pennsylvania School of Medicine Philadelphia, 1885, member of the Medical Society of Delaware, formerly United States Senator, aged 72, died, October 18, of pneumonia

Benjamin Franklin Carr, Polo, Mo., University of Missouri School of Medicine Columbia 1880, Jefferson Medical College of Philadelphia, 1886, member of the Missouri State Medical Association, aged 81 died, September 21

Olander E. Wald * Los Angeles, College of Physicians and Surgeons of Chicago School of Medicine of the University of Illinois, 1898 formerly on the staff of the Lakeview Hospital Chicago, aged 65, died, September 16

Edward Mayo Anderson, New Orleans, Tulane University of Louisiana School of Medicine New Orleans 1932 aged 27, on the staff of the U. S. Marine Hospital, where he died August 29 of subacute endocarditis

Ray C. Ash, Ashland, Ohio, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois 1904 served during the World War aged 53 died October 15, of chronic nephritis

Joseph Redmond Condon * Des Moines, Iowa, Northwestern University Medical School, Chicago 1908 aged 52 on the staff of the Mercy Hospital, where he died, October 12, of cardiorenal vascular disease

Frank Henry Wheeler * New Haven, Conn., Yale University School of Medicine, New Haven, 1882 past president of the Connecticut State Medical Society aged 77, died, October 10 of carcinoma of the cecum

James Edgar McKinney, Chesnee, S. C., Chattanooga (Tenn.) Medical College 1898, member of the South Carolina Medical Association, aged 64 died September 7, in the Spartanburg (S. C.) General Hospital

Harlin Andrew Harris, Guadalajara, Jalisco, Mexico, Syracuse (N. Y.) University College of Medicine 1903, chief surgeon to the Southern Pacific Railroad of Mexico, aged 52 died, July 7, of angina pectoris

John Dustin Howe * Tiffin, Ohio, Toledo Medical College 1891 veteran of the Spanish-American War, aged 72 died, October 11 in the Mercy Hospital of uremia and hypertrophy of the prostate

Clarence A. Rothwell, Mexico, Mo., Missouri Medical College St. Louis 1891 member of the Missouri State Medical Association, aged 67, died, September 30 of myocarditis and hypertension

George Livingstone Ellis, Middleboro, Mass., Harvard University Medical School, Boston 1872, member of the Massachusetts Medical Society, aged 94, died, August 22, of arteriosclerosis

Amos Evan Ayler, Greencastle, Ind., Southern Homeopathic Medical College Baltimore 1897, aged 62 died, October 14, in the Methodist Episcopal Hospital Indianapolis of heart disease

Matthew Alvin Barnes, Pardoe, Pa., Western Pennsylvania Medical College Pittsburgh, 1893 member of the Medical Society of the State of Pennsylvania, aged 69, died August 25

Henry St. George Strouse, Omaha, Neb., Hahnemann Medical College and Hospital of Philadelphia 1886 aged 65 died September 18 in the Douglas County Hospital, of myocarditis

James S. Cobb, Odessa, Del., Georgetown University School of Medicine Washington D. C. 1893 on the staff of the Kent General Hospital Dover aged 67 died September 28

George M. Kelly, North East, Pa., Western Pennsylvania Medical College Pittsburgh 1888 aged 69 died June 1, in St. Vincent's Hospital Erie, of uremia and prostatic hypertrophy

William Huffman Niles, Benton, Tenn., Atlanta College of Physicians and Surgeons 1913 served during the World War aged 46 was found dead September 21 of a gunshot wound

Ella Jane Fifield, Tacoma, Wash., Cooper Medical College San Francisco 1883 formerly member of the board of education aged 82 died September 30 of carcinoma of the uterus

Marian Elizabeth Parker * Kalamazoo, Mich., Syracuse (N. Y.) University College of Medicine 1926 on the staff of the Borgess Hospital aged 38 died September 8 of pituitary tumor

John Page McMahan, Peoria Ill., Rush Medical College, Chicago, 1883, member of the Illinois State Medical Society, on the staff of the Proctor Hospital, aged 75, died, October 5

Alpha Manly Chase, Denver, Colorado School of Medicine, Boulder, 1894, member of the Colorado State Medical Society, aged 60, died suddenly, October 6 of heart disease

Marshall Orlando Terry, San Diego Calif., Homeopathic Hospital College Cleveland 1872 veteran of the Spanish-American War, aged 85, died October 11, of lobar pneumonia

Shaen Saurin Magan ☉ Covina Calif., College of Medical Evangelists, Loma Linda, 1921 member of the Radiological Society of North America, aged 37, was drowned, August 31

Roswell Wetherbee, Belmont Mass., Harvard University Medical School, Boston 1882 member of the Massachusetts Medical Society, aged 75, died July 1, of cerebral hemorrhage

Byron J. Murray, Saratoga Springs, N. Y. University of Michigan Medical School Ann Arbor 1876 aged 83 died September 22, of cerebral hemorrhage and arteriosclerosis

Alfred Maucotel, Bay City, Mich., School of Medicine and Surgery of Montreal, Que. Canada 1877 aged 83 died October 16, in the Mercy Hospital, of pyelonephritis

Eugene Harp Dunnam, Houston Texas, Texas Medical College and Hospital Galveston 1875 aged 84 died September 29, of cardiovascular nephritis and myocarditis

David Le May Mitchell, Cassville Mo. Atlanta Medical College, 1874 Hospital College of Medicine Louisville, Ky. 1884, aged 84 died September 28 in Springfield

Cyrus Johnson McCombs, Matthews N. C. North Carolina Medical College, Davidson 1905 formerly health officer of Gastonia County, aged 53, died, September 27

Harry Norwood Street ☉ Lonoke Ark. Tulane University of Louisiana Medical Department New Orleans 1890 aged 65, died October 3, of chronic myocarditis

James Gordon, Columbia Mo. University of Missouri School of Medicine, Columbia 1881, formerly mayor of Columbia, aged 75, died, September 29, of pneumonia

Hilton A. Vickers, Youngstown, Ohio. Columbus Medical College, 1884 aged 76 died August 23, of myocarditis, hypertrophic cirrhosis of the liver and arteriosclerosis

Henry Armistead Bullock ☉ Richmond Va. University College of Medicine Richmond 1912 aged 42 died, October 2 in St. Luke's Hospital, of intestinal obstruction

William Frederick Kaercher, Philadelphia. Hahnemann Medical College and Hospital of Philadelphia, 1885 aged 73, died, October 13, of carcinoma of the prostate

George Arthur Dixon, Paris, France, College of Physicians and Surgeons, Medical Department of Columbia College New York, 1878 aged 76, died, October 14

Estus Leon Summers, Hattiesburg Miss., Memphis (Tenn.) Hospital Medical College, 1907 aged 52 died October 5, of hypertrophic cirrhosis of the liver

Howard A. Long, Brickerville Pa., Baltimore Medical College, 1893, member of the Medical Society of the State of Pennsylvania, aged 61 died, September 14

John H. Kiley, Blossburg Pa. Starling Medical College Columbus, 1886, member of the Medical Society of the State of Pennsylvania, aged 72, died, October 2

Harry M. Weed, Watersmeet, Mich. Chicago Homeopathic Medical College, 1889 aged 72, died, October 10, in Rhinelander, Wis., of cerebral hemorrhage

William T. Lovering ☉ Seattle, McGill University Faculty of Medicine, Montreal, Que., Canada, 1891, aged 65 died, September 20 following an appendectomy

Charles Henry Wilkinson, Denver. Cleveland University of Medicine and Surgery 1897 aged 65 died, October 7, in St. Anthony's Hospital of carcinomatosis

George Sewell Clark, Hartwell Ga. Atlanta College of Physicians and Surgeons, 1899 formerly chairman of the board of education died September 25

Henry F. Spillers, Dover Ark. (licensed Arkansas 1903) formerly superintendent of the Ohio Valley General Hospital, Wheeling, aged 53 died September 8

E. W. Dunn, Ferris Texas (registered by Texas State Board of Medical Examiners under the Act of 1907) aged 64, died, in October of heart disease

Lewis Henry Ferris ☉ Melbourne Iowa. State University of Iowa College of Medicine Iowa City 1912 aged 52 died September 16 of multiple myeloma

William W. Pritchard, Wichita Kan., University of Nashville (Tenn.) Medical Department, 1868, Civil War veteran aged 93, died, September 6

James William Watts, Columbus Ohio, Medical College of Ohio, Cincinnati, 1880, aged 78, died, October 12 in a local hospital, of carcinoma of the face

Lyman G. Hemenway, Sycamore, Ill. Bennett Medical College, Chicago 1877 member of the Illinois State Medical Society, aged 80, died, October 5

Lonam Samuel Johnston, Shreveport La., University of Pennsylvania School of Medicine Philadelphia 1907, aged 59, died June 11, of angina pectoris

Harris R. Moore, Burlington N. C. Atlanta (Ga.) College of Physicians and Surgeons, 1899, aged 60, died, September 30, in the Runcy Hospital

John H. Fritz, West Alexandria, Ohio. Eclectic Medical Institute Cincinnati, 1881, aged 81, died, October 18 in St. Elizabeth's Hospital, Dayton

Edwin Adolphus Gillespie, Memphis, Tenn. Vanderbilt University School of Medicine, Nashville, 1880, aged 77, was found murdered, October 12

Webster C. Montgomery, McLean, Texas. Atlanta (Ga.) Medical College, 1895, formerly city and county health officer aged 67 died, October 4

Charles Percy M. McCall, Jr., Reidsville, Ga., University of Nashville (Tenn.) Medical Department, 1904, aged 53, was found dead July 23

Cornelius Wesley Hickman, Houston Texas, Eclectic Medical Institute, Cincinnati, 1884, aged 78, died, September 30 of heart disease

Daniel Buchanan, Galt, Ont., Canada, University of Toronto Faculty of Medicine, 1896, aged 64, died suddenly September 7, in Detroit

Clarence Joseph Beekley, Cincinnati. Miami Medical College Cincinnati, 1901, served during the World War, aged 54 died, September 11

Lilburn Walter Huddle ☉ Rural Retreat, Va., Tennessee Medical College, Knoxville, 1907, aged 54, died, October 1, of cerebral hemorrhage

Robert Merritt Charlton, Hamilton, Ont., Canada. Western University Faculty of Medicine, London, 1906, aged 56 died, September 4

Rufus Edwin Hagerthy, Sedgwick Maine. Long Island College Hospital, Brooklyn, 1885, aged 74, died, September 3, of diabetes mellitus

Frederick Kilburn Priest, Nashua, N. H. University of the City of New York Medical Department, 1882, aged 73, died, September 28

Gordon Way Hoyt, Syracuse N. Y., Hering Medical College Chicago 1896, aged 60, died, October 8, of streptococcal meningitis

Noah Myers, Springfield Ohio. Medical College of Ohio Cincinnati, 1887, aged 74 died suddenly, October 13, of cerebral hemorrhage

Roy Leon Chambers ☉ Sardinia Ohio. Starling Ohio Medical College, Columbus, 1909, aged 48, died, October 16, of heart disease

Vestus E. D. Casselman, Vancouver B. C., Canada. Manitoba Medical College, Winnipeg, 1897, aged 63, died September 16

Warren Edward Hillyer, Boulder, Colo. Keokuk (Iowa) Medical College, 1898 aged 61, died suddenly, October 14, of heart disease

Alfred E. Long, Vancouver B. C. Canada. University of Pennsylvania School of Medicine, Philadelphia, 1882, aged 84, died July 26

Roger Sherman Tea, Lafayette Ind. Rush Medical College Chicago 1886 aged 75 died October 2, of cerebral hemorrhage

George H. Mathews, Union Springs, N. Y. Baltimore Medical College 1884, aged 88, died, July 21 of chronic endocarditis

Jesse Bell Holt, Culver City Calif. Woman's Medical College of Pennsylvania Philadelphia 1884 aged 75, died July 16

William Jenkins Fernald, Ontario Calif. Rush Medical College Chicago, 1890, aged 69 died in October of heart disease

George Robert Connally, Wichita Falls Texas, nongraduate aged 80 died July 23 of cholecystitis

Bureau of Investigation

BEER AND ALCOHOL

Some Alcoholic Percentages in Beers on the American Market

The passage this spring of an act to provide revenue by the taxation of beer and the coincident repeal of certain paragraphs in the National Prohibition Act so as to permit the legal manufacture and sale of beer containing not more than 3.2 per cent of alcohol by weight have stimulated public interest in the subject of alcohol percentages in American beers. At the time the act was passed it was freely stated, and the claim is still heard, that beer containing 3.2 per cent of alcohol by weight (which is about 4 per cent by volume) must be a pretty "weak" affair, and in no way comparable to the general run of beers legally sold in the United States prior to the adoption of the Eighteenth Amendment to the Constitution. It has also been suggested that the "new" beer does not even contain the amount of alcohol that the modification of the law permits—in other words, that the beer put on the American market does not contain 3.2 per cent of alcohol by weight. This rumor is given further weight by the fact that the declaration of alcohol content, which the National Food and Drugs Act requires, does not state "Contains 4 per cent of alcohol by volume," but instead, more ambiguously declares "Contains not more than 4 per cent of alcohol by volume."

In view of the vagueness in the public mind—not wholly confined to the nonmedical part of the public—regarding the alcohol content of beverages, it may be of interest to call attention to certain fundamentals underlying the problem. At the outset, it is to be remembered that the National Food and Drugs Act requires the declaration of the presence and amount of alcohol in all drugs and beverages containing that substance. The law further requires that such figures shall be expressed in percentages by volume—not by weight—and also in percentages of *absolute* alcohol. This fact should be borne in mind, because in Canada and Great Britain the alcohol content of beverages is usually declared in terms of proof spirit, which is one half the strength of absolute alcohol. Thus the beers legally sold in taverns in the Province of Ontario and advertised as "4% by volume" are, if expressed in the terms required by our Food and Drugs Act, actually 2 per cent by volume.

The reason the new law uses weight instead of volume as the unit of alcoholic strength is probably to be explained on political and psychological grounds. Those desirous of legalizing the manufacture of beer containing a higher percentage of alcohol than the one-half of one per cent designated under the National Prohibition Act were undoubtedly aware of the ignorance of the general public of the differences between percentages by weight and percentages by volume. It might have been more difficult to get the necessary legislation to permit the manufacture of beer containing 4 per cent of alcohol by volume than it was to get the same legislation to permit the making of beer containing 3.2 per cent of alcohol by weight—although as a matter of fact, the latter represents a slightly higher percentage of alcohol than the former. The following alcoholometric table, from 1 per cent to 10 per cent by volume taken from the United States Pharmacopoeia, will give some idea of the differences between percentages by volume and percentages by weight.

ALCOHOL BY VOLUME		ALCOHOL BY WEIGHT
1 per cent	=	0.795 per cent
2 per cent	=	1.593 per cent
3 per cent	=	2.392 per cent
4 per cent	=	3.194 per cent
5 per cent	=	3.998 per cent
6 per cent	=	4.804 per cent
7 per cent	=	5.612 per cent
8 per cent	=	6.422 per cent
9 per cent	=	7.234 per cent
10 per cent	=	8.047 per cent

Prior to the national prohibition law, the better known American lager beers declared the presence of between 3.5 and 4.5 per cent absolute alcohol by volume. Bringing the facts down to date, there is published by the New Hampshire State Board of Health, in its *Monthly Bulletin* for October, this year, a list of beers, the sale of which has been legalized by that state, together with the percentages of alcohol found by recent analyses to be in such beers. The following products and figures are taken from the *New Hampshire Bulletin*. In some instances more than one analysis was made with slightly varying results. In such cases, instead of giving the individual alcohol percentages by volume in each analysis, the figures given have been averaged.

	Alcohol per cent by volume
Banquet Ale (Narragansett Brewing Co.)	4.00
Bass Ale (Read Bros. Ltd.)	3.82
Blue Ribbon (Premier Pabst Corp.)	3.88
Boston Stout (Commercial Brewing Co.)	3.55
Budweiser (Anheuser-Busch Inc.)	3.84
Burgomaster (Fitzgerald Bros. Brewing Co.)	3.57
Connecticut Valley Ale (Connecticut Valley Brewing Corp.)	3.96
Connecticut Valley (Connecticut Valley Brewing Corp.)	3.89
Dawson's Diamond Ale (Dawson's Brewery Inc.)	3.84
E. B. C. Portsmouth Ale (Eldredge Brewing Co. Inc.)	4.10
Edelbrau German Lager (Edelbrau Brewing Co.)	3.86
Genesee (Genesee Brewing Co.)	3.34
Gilt Edge Stock Ale (Cold Spring Brewing Co.)	3.64
Golden Rod Lager (Hittleman Golden Rod Brewing Co., Inc.)	3.80
Gold Medal (Munich's Brewery Inc.)	3.79
Gold Medal (Stegmaier Brewing Co.)	3.64
Haffenreffer's Lager (Haffenreffer & Co.)	3.94
Hampden Ale (Hampden Brewing Co.)	3.92
Hampden Lager (Hampden Brewing Co.)	3.63
Horton Pilsener (Horton Pilsener Brewing Co. Inc.)	3.66
Harvard Draft Lager (Harvard Brewing Co.)	3.64
Heineken's Dutch (Heineken's Breweries)	3.57
Heineken's Lager (Heineken's Breweries)	3.46
High Life (Miller Brewing Co.)	3.84
Kings (Kings Brewery Inc.)	3.49
Kings Special Ale (Kings Brewery Inc.)	3.61
Liebschauer (Genesee Brewing Co.)	3.84
Liberty (American Brewing Co.)	3.98
Michel Pilsener (Michel & Ebling Brewing Co.)	3.72
Narragansett Lager (Narragansett Brewing Co.)	3.52
Old England Ale (Old England Brewing Co.)	3.93
Old Heidelberg (Harrison Beverage Co. Inc.)	3.39
Old Heidelberg Pilsener (Union City Brewing Co.)	2.97
Old Homestead Ale (Commercial Brewing Co.)	3.71
Ortleib's Lager (Henry F. Ortleib)	3.29
Paramount (North American Brewing Co.)	3.69
Pickwick Ale (Haffenreffer & Co.)	3.80
Pico Pilsner (Pilsner Products Co. Inc.)	3.74
Piel's Dark Lager (Piel Bros. Inc.)	3.85
Piel's Light Lager (Piel Bros. Inc.)	3.88
Rheingold (Liebmann Breweries Inc.)	3.73
Schlitz (Schlitz Brewing Co.)	3.36
Seitz (Seitz Brewing Co.)	3.42
Standard (Standard Brewing Co.)	3.49
Stegmaier's Porter (Stegmaier Brewing Co.)	3.35
Stegmaier's Select (Stegmaier Brewing Co.)	3.63
Stegmaier's Stock Lager (Stegmaier Brewing Co.)	3.66
Tip Top Lager (Trainer Brewing Co.)	3.80
Utica Club Brew (West End Brewing Co.)	3.68
Wehle Ale (Wehle Brewing Co.)	3.20
Wehle Lager (Wehle Brewing Co.)	3.56
Whitbread Pale Ale (Whitbread & Co. Ltd.)	3.87

The analyses of these fifty-two brands show the average alcoholic strength to be 3.68 per cent by volume.

An Ultramicroscopic Living Thing—Yellow fever is caused by a virus, an ultramicroscopic living thing that has never yet been seen. Able to pass through the closest of filters, it has been known to penetrate the skin of a man's hand and infect him with the disease. Despite this penetrative power the disease is not ordinarily acquired by contagion, being like many other diseases, spread through the agency of an insect host. The host a mosquito, bites an infective man and twelve days later becomes infective itself and remains so for the remainder of its life, which may last for some months. At any time during its infective period the mosquito has only to bite a human being once for the virus to be passed back from its insect to its human host and for the disease to spread. —Still John. The Significance of Yellow Fever, *J. Royal Army Med Corps* 61: 268 (Oct.) 1933.

MALNUTRITION IN CHILDREN

To the Editor—I have just read your editorial October 21, on malnutrition in children. Since the Washington meeting, October 6, I have been looking into this question in the dispensary and children's wards of the Philadelphia General Hospital, where I find from records of social workers and dispensary physicians, and in my wards, that there is distinctly less malnutrition in children than there was in much better times. So far, there has been only one true case of malnutrition in the wards this month which is distinctly unusual.

Most of our patients come from homes that are being supplied with food from different agencies in the city, and my feeling is that the children are getting much more nourishing food than they had obtained when the parents were self supporting and supplying much unnecessary and faulty foods. In my own practice I have not seen any cases of malnutrition even when the parent or parents have been out of work or had only enough work to supply the absolute necessities of life. I feel that it is entirely wrong to make so much hullabaloo about something which does not exist.

THEODORE LEBOUTILLIER, M.D., Philadelphia

ABORTIONS IN RUMANIA

To the Editor—I was greatly surprised to read in the Bucharest letter (THE JOURNAL, September 2 p. 792) that the number of abortions registered in statistics is about 60,000 a year. I will not discuss the figure although my associates and I are the only ones in Rumania who could be well aware of the actual number. I have no idea as to the number of abortions that take place here. Two expressions of a contradictory nature—'secret abortions' and 'late statistical reports'—are used by the correspondent.

The causes of death registered according to the International List give the following data for 1931 and 1932:

	Total Deaths in Rumania	Number of Females Between 14 and 45 Years Dying from All Causes	Total Female Deaths from Puerperal Causes
1931	380 251	30 543	2 389
1932	399 346	28 653	2 889

S MANUILA, M.D., Bucharest, Rumania
Director of the Institute of Demography and Census

SPRAY RESIDUE POISONING FROM STRING BEANS

To the Editor—Spray residue poisoning, in man, occurs with some frequency. A recent instance in San Francisco is worthy of note.

Mrs. M., a housewife, served a meal consisting of string beans, summer squash, boiled rice, dried cooked peaches, and, to one individual only, broiled steak. Seven people including three children of 10, 6 and 2 years, and four adults were served. Mrs. M. was the only one affected, but also she was the one of the group who ate an additional portion of the string beans, an incident occurring about one hour after the meal. Physical signs and symptoms complained of included nausea, vomiting, diarrhea, headache, abdominal pain and 'dark spots before the eyes'. The disturbance endured through three days for forty-eight hours.

Samples of the beans were obtained from the market and were prepared in the same aluminum vessel as before and chemical studies revealed lead to the quantity of 117 mg (0.0117 Gm) per hundred grams of beans but no arsenic. Three other samples from the market showed no lead or arsenic.

Quantities of the beans sold were procured by the market from two different sources on two successive days, so that it was impossible to trace the responsible lot.

From the amount of insecticides sold per capita annually, it would appear that relatively enormous quantities are used. Heavy spraying might easily permit the quantity of residue to exceed the rather wide margin of safety for human consumption. The possibilities are minimized, of course, by the supervision offered by the Bureau of Entomology and Plant Industry of the United States Department of Agriculture and by state departments of agriculture. It is to be remembered, however, that the uninformed truck farmer, to insure an effective dose of insecticide, may spray his vegetables heavily. If the housewife is not extremely cautious in washing the spray residue from the vegetables before cooking, a case of poisoning may easily result.

J. C. GEIGER, M.D., San Francisco

Director of Public Health

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

HYPERHIDROSIS, OR EXCESSIVE PERSPIRATION

To the Editor—A youth aged 19, height 5 feet 8 inches (1.77 cm.), weight 152 pounds (69 kg.) of normal bodily development complains that for the past four years he has been bothered with excessive perspiration. Irrespective of the surrounding temperature, winter or summer, he perspires so freely that his clothing becomes soaked through in a short while. It has become so severe that it practically bars him from any form of social activity, such as dancing, unless he was to change his clothing several times during an evening. He drinks large quantities of water. The perspiration is generalized over the body surface, head and scalp. The past history and physical examination are entirely negative. He has an older sister aged 28 with diabetes mellitus. Routine blood examinations and urinalysis are within normal limits. The Kahn and Wassermann tests of the blood are negative. His only other complaint is an occasional frontal headache. A course of several intramuscular injections of solution of pituitary produced no appreciable effect on the thirst or perspiration. The patient is becoming quite despondent over the situation and is willing to try any measures to check this condition. Kindly omit name.

M.D. Illinois

ANSWER—Many of the causes of generalized hyperhidrosis can be ruled out in this case by the description given, but a few remain as possibilities: Malaria, hyperthyroidism, hyperglycemia, persistent, nonprogressive brain lesion or a neurosis, based on fear may be considered.

Periodicity in the attacks would suggest malaria. Hyperthyroidism should have produced symptoms recognizable in the general examination. If any suspicion of this disorder can be entertained, an estimation of the basal metabolism should be made. Evidence is wanting of direct causation of hyperhidrosis by disturbances of the pituitary gland, but excessive sweating occurs at times in gigantism probably from the accompanying hyperthyroidism. Hyperglycemia, too, may be secondary to pituitary disease. Urinalysis should be repeated and the blood sugar estimated before it can be excluded.

Hyperhidrosis has often been reported in cases of dementia paralytica, myelitis, injury or tumor of the brain. In spite of the fact that the condition has been present for four years without causing any other symptom, this possibility should be ruled out by careful examination, including examination of the eyegrounds. There have been a number of cases of self-limited general hyperhidrosis reported in which no etiologic factor could be found. The theory has been offered that they were due to a temporary vasomotor disturbance in the corpus striatum or hypothalamus consequent on some infective process.

If no etiology can be discovered, empirical treatment might well be instituted by putting the patient in the hospital, cutting down water and salt to the minimum and recording the amount of perspiration. It must be remembered that the loss of water and salts in the sweat causes hypochloremia, so that the hyperhidrosis patient needs more salt than a normal person. If this does not break the cycle, the remedy most likely to give relief is atropine administered in increasing doses until the desired effect is obtained or signs of intolerance appear.

An old wives' remedy, sage tea, is recommended by good German authority as having succeeded in some cases. It must

be given in large amounts, and after it has been used for several weeks it should be stopped for a few days to prevent loss of effect and then resumed. Other authorities report success for sulphur in doses of 4 Gm morning and evening. Still others report good results from emphyron in pills coated to prevent solution in the stomach. Other patients have been benefited by iron, some by ergot, a number by arsenic.

The use of external applications is sometimes indicated as an adjuvant. One per cent solution of liquor formaldehydi in water is the most generally useful. One per cent alcoholic solution of quinine has succeeded in some cases, probably those resulting from malaria.

DWARFISM

To the Editor—A boy was brought to my office a few days ago with I believe some type of glandular disturbance possibly an insufficiency of the anterior pituitary. The child is now 13 years old, height 45 inches (114 cm) and weight 48 pounds (22 kg). He was a full term baby, born after a long labor with forceps delivery and weighed 5 pounds (2.3 kg) at birth. He was breast fed until 18 months old. He cried a good deal until he was about 3 months old. He was apparently a normal child according to his mother until he was 4 years old and then he just seemed to stop growing. There is no history of convulsions or illness of any kind in early infancy. He had measles four years ago, mumps three years ago and acute bronchitis one year ago. There is nothing in the family history of importance. There is one other child in the family, a girl of 10 who is apparently normal and in good health. There is no one on either side of the family of small stature. Physical examination is negative except for his stature. The size of his chest and abdomen is possibly a little out of proportion to the remainder of his body. He appears to be thick and fat through the chest and abdomen. Otherwise the relationship in size between the head, extremities and trunk is normal. There is apparently no disturbance in the secondary sex characteristics. His progress in school has been satisfactory and there is apparently no mental retardation. Can you offer any suggestion as to the possible diagnosis and is there any glandular therapy that might prove of value in this case? Can you give me any reference to the literature? Please omit name and address.

M D Texas

ANSWER—The history of this case and an examination of the photographs submitted suggest dwarfism. The patient described in the query progressed normally until he was 4 years old and then ceased growing. This type has been referred to as the infantile variety. Growth continues for a certain period and ceases some time between childhood and puberty. Such an individual may become a man in miniature. Paltauf in 1891 called attention to another variety, the primordial type of true dwarfism. These are congenital dwarfs. They may take on growth acceleration in adult life. Thus it is recorded by Paltauf that two dwarfs increased in height as late as their thirtieth year. In most of the cases belonging to the primordial group the intelligence remains normal. The etiology is obscure, though retardation in development of the epiphyses persists and seems in some way to be associated with the failure to grow.

Pituitary preparations have been employed to a considerable extent in the treatment of dwarfism. It is difficult to say whether observations of accelerated growth are due to pituitary medication or are simply spurts in growth, which take place even in untreated cases. It has been suggested that, if results are to be obtained, large doses of the preparations should be used—as much as from 2 to 4 Gm a day.

In several laboratories the growth fraction of pituitary extracts in concentrated form have been isolated. Thus Shelton of Santa Barbara has recently treated a midjet by giving Evans growth hormone hypodermically.

A discussion of dwarfism may be found in any of the recent textbooks on medicine or pediatrics and it is also considered in Linglebrich's *Endocrine Medicine* published by Charles C. Thomas in 1932. R. G. Hoskins' *The Tides of Life* published by W. W. Norton & Co. in 1933, and W. Falta's *Endocrine Diseases* translated by M. K. Meyers in 1923.

WATER HEMLOCK POISONING

To the Editor—In *THE JOURNAL*, September 9, there is a clinical report of a case of water hemlock poisoning by Dr. M. M. Miller of Akron, Ohio. I have a vague recollection that several years ago *THE JOURNAL* published the experience of a physician in the management of a large number of victims of intoxication by the same plant in a public institution for children. As young persons seem to be the common victims of innocent eating of the widespread *Cicuta* genus, I opine that other readers would be glad like myself to have references to the subject.

M D Connecticut

ANSWER—The communication to which our correspondent doubtless refers was a report of seventeen cases of poisoning with water hemlock (*Cicuta maculata*) published in some detail by the late Prof. Louis A. Gompertz, M.D. of the Yale University School of Medicine (*THE JOURNAL*, Oct. 16, 1926, p. 1277). It dealt with a group of boys, inmates of a county home who

had been taken suddenly ill after partaking of the leaves or flowers and, in a few instances, of the roots of water hemlock growing in a swamp adjoining the children's playground. All those who had eaten root stocks became ill, with accompanying convulsions. The symptoms otherwise resembled those described by Miller. All of Dr. Gompertz's seventeen patients recovered. The treatment consisted of gastric lavage and high enemas. After the stomachs of all were evacuated it became necessary, in some instances, to administer morphine hypodermically. Active purgation was initiated in each child. Otherwise, they were treated symptomatically. Dr. Miller employed sodium amylal, 0.2 Gm, administered intravenously, to overcome the alarming convulsions.

Extensive references to the literature of poisoning with *Cicuta* will be found in Dr. Gompertz's paper. It is evident that water hemlock is highly poisonous at all times. The problem of prevention emphatically presents itself. Attention should be called to the widespread menace of the plant. Eradication procedures ought to be inaugurated so thoroughly in all neighborhoods where children, the usual victims, are likely to play that the future possibility of poisoning by *Cicuta maculata* will be reduced to a minimum. Its habitat is among swamps, frequently it is found along irrigating ditches and wild meadows.

ENCEPHALITIC PARKINSONISM

To the Editor—I have a patient who suffered from epidemic (lethargic) encephalitis about ten years ago. Since his recovery he has been suffering from paralysis agitans. Two years ago he came to me for treatment and I gave him tincture of stramonium, 10 drops three times daily. This dosage had to be increased to 30 drops and even more. I stop this treatment for intervals of two weeks but he seems to have developed such a tolerance for the drug that even more than 30 drops three times daily does not seem to help. Kindly let me know whether there is anything new that could be used. His age is 28 years.

SAMUEL ZEAVIN, M.D., Austin, Manit.

ANSWER—It is difficult to recommend something new when none of the new remedies recommended for encephalitic parkinsonism are as good as stramonium, atropine and scopolamine hydrobromide. The latter is usually the most efficient drug. It is well to begin with 0.3 mg. three times a day and gradually increase the dose as needed. In addition to this a course of intravenous injections two or three times a week for a month or two of sodium cacodylate may be beneficial. It is well to begin with 0.3 Gm and gradually increase the dose to 1.3 Gm. If the scopolamine should prove ineffective, it would be safe to increase the dose of tincture of stramonium to double the amount stated. The powdered leaf in capsule may be more effective, beginning with 0.13 Gm three times a day.

ACCUMULATION OF TARTAR ON TEETH

To the Editor—What causes an excessive accumulation of tartar on the inside of the lower front teeth which returns soon after prophylaxis? A man aged 40 has chronic tuberculosis of long standing. He has obstinate constipation for which he has taken psyllium and a daily dose of two teaspoonfuls of magnesium magna for several years. There is no apparent lack of salivary secretion. Nearly all the teeth are present, apparently in good repair. He is a mouth breather. A reply will be appreciated.

M D, North Carolina

ANSWER—Some authorities believe that from 90 to 95 per cent of all pyorrhea can be regarded as a fifth disease. The small minority is of constitutional origin. In evolution man has lost the art of vigorous mastication, a diet has been adopted that is for the most part made up of soft foods. If foods were hard and tough, the teeth would be cleansed and the gums vigorously massaged or stimulated during mastication. Some cleansing and massaging are not automatic now, it becomes necessary to supply both artificially. As a result, proper brushing of the teeth has become an important function. This fact is little appreciated by the dental profession as a whole, therefore it is not emphasized to the lay public. Unless much attention is given to the gums during tooth brushing, they become soft and spongy and as a result fit loosely about the necks of the teeth. Under such conditions it is not surprising to find tartar collecting on the necks of the teeth. Tartar is the result of the calcification of organic matter deposited on the teeth. It always consists of degenerated epithelial cells of the mouth mucous membrane, food debris, mucus of the saliva and various microorganisms of the mouth. In the beginning the formation consists of a soft film of the substance of these can easily be brushed away if done thoroughly and frequently every day. If this is neglected the film hardens and is calcified by the inorganic salts of the saliva. Chemical analysis shows considerable variability in the composition of the film, figures are a fair average: calcium phosphate 70 per cent, calcium carbonate 20 per cent, and organic matter 10 per cent.

10 per cent, water and organic matter, 20 per cent. Hard tartar contains a much higher percentage of inorganic salts, soft tartar a higher percentage of organic matter and water. The tendency to tartar formation varies with individuals, also with age. The soft type predominates in youth and the hard type in older persons.

The accumulation of tartar can be controlled effectively by proper brushing. A thorough prophylaxis by a dentist is of limited benefit to the patient unless he knows how to follow up this service. There are two good reasons why tartar accumulates more readily on the inside of lower teeth than anywhere else. First this is the most difficult location to brush, second, the sublingual and submandibular glands are closest to these surfaces. If equally poor brushing were done on all other tooth surfaces, much tartar would gather there also.

The recommendation is that the patient acquire two good hard bristle tooth brushes and learn how to use them. By alternating morning and night the bristles have more time to dry out. Proper brushing essentially constitutes a vibrating motion with pressure rather than a long stroke motion which results in nothing more than brushing the high spots. Cleaning agents are aids only if used in conjunction with a thorough brushing technique. Tooth pastes do not yet possess the magic properties that some advertisers would have us believe.

INSULIN AND UNDERWEIGHT

To the Editor—I have under my care a woman aged 20 who is about 30 pounds (13.6 kg.) underweight. She tried all sorts of tonics but could not gain. Physical examination is entirely negative except for the underweight. I put her on insulin 5 units three times a day. At first she responded to this treatment by getting hungry about thirty minutes after the injection but after five or six days this dose ceased to have any effect at all. The dose was then increased to 10 units three times a day. For the first few days she used to get hungry about thirty or forty minutes following the injection later the interval between the injection and the onset of hunger was prolonged to about eighty or ninety minutes and finally this dose failed to produce any hunger at all. I then started her on 20 units three times a day and for the first two or three weeks she reacted favorably by getting hungry but not until about ninety minutes following the injection. I now find that I have to give her at least 30 units in order to produce a hunger sensation and that only after eighty or ninety minutes. Kindly answer the following question: Do you consider such a long interval between the time of injection and the onset of hunger unusual? Do patients become tolerant to insulin and require larger doses when treatment is prolonged? 3. Is 30 units three or four times a day harmful in any way? 4. In the event that 30 units will soon fail to produce a hunger sensation would you advise increasing the dose to 40 or 50 units three times a day? 5. During the three months that she has been under insulin treatment she gained 14 pounds (6.4 kg.) without discontinuing her work as an office clerk. Is this the usual rate of gain in weight? What is the optimum rate of weight gain? I shall greatly appreciate your courtesy in this matter. Please omit name. M. D. New York.

ANSWER—Hypoglycemia following the administration of insulin to normal persons usually reaches its lowest point in from two to three hours. The sensation of hunger coincident with the lowering of the blood sugar although it may supervene when the blood sugar level has fallen as little as 10 mg. per hundred cubic centimeters may be delayed until the sugar has approached its lowest levels.

The lowering of the blood sugar level evokes compensatory reactions within the organism which involve the utilization of the stored glycogen as a source of sugar with which to replenish the blood. In the undernourished person, in whom the compensatory mechanisms are hampered by lack of sugar stores, the hypoglycemic action of insulin is more precipitous than in the well nourished organism. The apparent increasing resistance of the patient to insulin is probably due to the improvement in her nutrition as a result of treatment. In the absence of complications such as infection diabetic patients receiving insulin over long periods do not develop any resistance to insulin.

The possible harm that might result from continued insulin administration in a normal person can be surmised only from certain theoretical considerations and, for the present at least may be neglected. However the increase in weight that occurs during insulin therapy is chiefly due to an increase in the food intake. Although water retention accounts for some of the gain in weight and while certain investigators have ascribed some of the benefit derived from insulin to its influence on the intermediary metabolic processes, the rationale of the treatment is mainly to improve the feeding habits. Since this patient has been receiving insulin for more than three months which should be a long enough period in which to establish improved feeding habits there seems little purpose in continuing the administration of increasing doses of insulin. Once a normal food intake has been established there is no more reason for inducing extreme hunger reactions at mealtime in such patients

than in normal individuals. In view of this and since most workers have not used more than 20 units of insulin three times a day in this work, it would seem advisable to discontinue the insulin in this case and observe what lasting effects have been obtained with it. It can be resumed later if necessary.

As compared to the experience of others, the gain of 14 pounds in three months is not excessive. Greater increases have been reported.

CONTAGIOUS AND INFECTIOUS DISEASES

To the Editor—Please distinguish between contagious and infectious diseases, give definitions, also examples with reasons. If smallpox is a contagious disease why is it not infectious? If malaria is infectious why is it not contagious? THOMAS S. LEMING, M.D. Moberly, Mo.

ANSWER—The only distinction between contagious diseases and other infectious diseases lies in the manner in which the infecting agents are transmitted. Contagious diseases are infectious diseases that are spread to susceptible persons through contact with specific infectious material without the intervention of an intermediary host in which the infectious agent may undergo certain changes or stages in development. Smallpox, chickenpox, gonorrhea, syphilis, scarlet fever, measles, mumps, diphtheria, whooping cough, epidemic meningitis, puerperal fever, erysipelas and pneumonia are all examples of contagious diseases in this sense and they are all infectious diseases. Smallpox is an infectious disease. But not all infectious diseases are contagious in the sense just stated. Malaria, yellow fever, trypanosomiasis and Rocky Mountain spotted fever are not transmissible by simple contact with specific infecting material. These diseases are transmitted by the bite or sting of insects that carry the infecting agent and deposit it in virulent form in the tissues or blood of the victims. It is true that these diseases are communicable diseases, but not by simple contact, hence they are not contagious.

NECROSIS OF FATTY TISSUE AFTER HYPODERMOCLYSIS

To the Editor—In January I saw a patient who had been having convulsions for several hours. A woman at full term was in a state of coma with elevation of blood pressure and pathologic kidney, the typical picture of advanced eclampsia. I advised cesarean section immediately as she was at full term a primipara 34 years old and fetal heart sounds could be heard. A twin pregnancy was found, a boy and a girl. The boy seemed to have been dead for several hours but the girl came through in good condition. The patient left the operating table in fair condition. A hypodermoclysis was ordered on her return to her room. My personal contact with the case terminated at this point for a period of several weeks. I understand that a hypodermoclysis of 5 per cent dextrose in physiologic solution of sodium chloride was given immediately after her operation and repeated eight hours later. About six weeks following her operation the woman consulted me with reference to a painful condition on both sides of the chest wall. On the right side a fluctuation area was found just below and posterior to the level of the breast. Marked tenderness was found over the same area of the other side but no fluctuation was found. I advised her to return to her local physician and consult him with reference to the matter which she did. A few days later she came back to me and the same condition persisted. I made an opening just below and slightly posterior to the breast and several ounces of straw colored fluid was removed. I saw the woman over a period of several months and it became necessary to make numerous openings on both sides of the chest wall below and posterior to the breast and extending down to the level of the umbilicus. Always the same character of fluid was found. A straw colored rather thick and sticky fluid was recovered but never at any time was pus found. The fluid was examined microscopically on numerous occasions and one culture was made but both procedures were negative for organisms. The skin was never involved. The pathologic condition was confined to the superficial tissue between the skin and muscles of the chest wall. All symptoms finally cleared up about eight or nine months after operation and the patient is entirely well except for a hernia in the upper portion of the incision in the region of the necrosis. Some controversy has arisen with reference to this matter and I was asked for an opinion as to the cause of the necrosis. My idea was that it was simply a fatty necrosis as a result of the hypodermoclysis being given either too hot or too strong. I say this because the necrotic area involved only that portion of the chest wall which is supposed to have absorbed the hypodermoclysis. Also it was not the marked localized necrosis which is usual from overdilatation of the tissues. Some expressions from you with reference to the causes of necrosis or any information you might give me would be greatly appreciated. Please omit name. M. D. Mississippi.

ANSWER—The inquirer is most likely correct in his assumption that the fluid was the result of necrosis of fatty tissue and that the necrosis was most likely due to the fact that the solution injected was too hot. De Lee (Year Book of Obstetrics and Gynecology by J. B. De Lee and J. P. Greenhill 1925, p. 213) reports such a case. The absence of more local and general symptoms, the negative cultures and the fact that the necrosis was bilateral all speak against an infection. If epinephrine was added to the solution before it was injected it may have caused the necrosis. Vignes (*J. de praticiens* Jan. 31, 1925) reports a case in which complete necrosis of the mammary

gland followed a submammary injection of serum. The entire breast separated from the chest wall without bleeding. Vignes believed the necrosis was due either to epinephrine or to the fact that the serum was too hot. He has seen a number of sloughs follow injection of epinephrine in pregnant women. He emphasizes that in gravid women there is hyperactivity of the suprarenal glands and that, when additional epinephrine is injected into the body, necrosis may result from excessive vasoconstriction in the area of injection. However, while this is most likely true if only a small amount of epinephrine is used there is no harm, as evidenced by the fact that necrosis is rarely ever seen after the use of infiltration anesthesia. In practically all cases in which this form of anesthesia is used, some epinephrine is added to the anesthetic. In the case cited the patient's resistance was lowered considerably by the eclampsia and this may have played a part in the necrosis.

BLOOD TRANSFUSION IN SHOCK

To the Editor—What is the consensus as to the indication or contra indication of blood transfusion in a case of shock not due to hemorrhage? Recently there was a paper or an editorial in *THE JOURNAL* on shock in which this subject was discussed. Would you be kind enough to give me the reference?

MARTIN M. SHIR, M.D., Brooklyn

ANSWER—Blood transfusion is indicated when, as a result of an operation or trauma or burns or uncomplicated hemorrhage, the blood pressure remains depressed definitely below its normal level. If the blood pressure has remained at a very low level for several hours as a result of any of these causes the transfusion of blood may be without a sustained beneficial effect. The editorial on shock appeared in *THE JOURNAL*, January 7, page 46.

LATE EFFECTS OF TRICHINOSIS

To the Editor—A man aged 40 had a severe and typical attack of trichinosis in 1928. He had at that time an eosinophilia of 50 per cent. Some residual pains continued in the muscles of the extremities. Blood examination six months after the initial attack revealed an eosinophilia of 9 per cent. For more than four years there were no symptoms. Recent fleeting pains, at times very severe, have occurred in the extremities at times these were associated with some transient swelling. The character of these disturbances has been very similar to what one would expect in a subacute phase of trichinosis and would be more readily classified than in any other type of muscular neuritic or joint problem. There is no fever at present and the blood picture is hemoglobin 75 per cent, red blood cells 4,470,000, white blood cells 9,500. The latter show 77 per cent neutrophils and no eosinophils. Do you feel that after this long free interval the present trouble can be attributed to the previous attack of five years ago? Please omit name.

M.D., Illinois

ANSWER—The fleeting pains which the patient has in the extremities at the present time are probably not due to the trichinosis. The parasites soon develop a calcium capsule and from then on (while they remain in the muscle) do not cause any symptoms.

TYPHOID IN BIRDS

To the Editor—I should like to know whether any experiments have been made on the feeding of typhoid to healthy and sick birds and pigeons. If such experiments have been made would the germs after passing through the digestive system be infectious?

PAUL SERRE, Dixmont, Pa.

ANSWER—Few experiments seem to have been done on this subject. The experimental study of chickens as possible typhoid carriers made by Mitchell and Bloomer (*J. M. Research* 31:297, 1914) indicated that these birds could not be infected either by intravenous inoculation or by feeding. The feces of chickens fed with material containing typhoid bacilli over a period of nineteen days were subjected to daily bacteriologic examination but never showed the presence of typhoid bacilli. The apparent destruction of typhoid bacilli in the alimentary tract of chickens is in line with what has been observed when typhoid bacilli have been fed to certain mammals, as calves.

AMITOSIS

To the Editor—What cells in the human body divide only by amitosis? Are there any cells that divide on some occasions by mitosis and at other times by amitosis?

B. L. Knight, M.D., Cedar Rapids, Iowa

ANSWER—All observations on amitosis as a means of growth have been attacked because they are in conflict with the chromosome theory of inheritance. There is no evidence in man for cell growth of this type which meets the criticisms raised. Adequate material is difficult to obtain and many pitfalls await the observer. Amitosis immediately followed by mitosis has been described in rapidly growing tissues of rabbit and pigeon embryo. In various mammals evidences of amitosis have been

found in developing connective tissue, cartilage, bone and muscle. There is no valid reason for doubting similar cellular phenomena in human development. Amitosis as a means of increasing nuclear surface is well established in the fetal syncytium of the human placenta. The binuclear cells in the human liver, in the stomach, in the outer layers of stratified epithelium and in cartilage as well as in some types of multinuclear cells are probably the results of direct nuclear division. In these cases as in the polymorphonuclear leukocytes the object would also seem to be an increase in the reacting surface.

HAWKING

To the Editor—I am in search of a word to convey the action in which subjects suffering with drippings behind the nose get rid of this mucus from within the nose and drippings of the posterior fossae and subsequently expectorate them. The word is to convey that action which draws backward the mucus and the phlegm of the nasal channels and is expectorated.

T. J. DIXIEY, M.D., New Orleans

ANSWER—The term "hawking" is the one most commonly used to describe the action of drawing down from the nasopharynx secretions lodged behind the nose. In some cases the same term is used to designate the act of dislodging mucus resting on or near the vocal cords and then it is usually accompanied by a short cough-like explosive expiration.

USE OF PEPTONE ORALLY

To the Editor—On page 730 of your issue of Aug. 26, 1933, under the title of Angioneurotic Edema you suggest peptone orally as a possible treatment. Would not any protein by mouth provide peptone? The rationale of peptone parenterally is comprehensible to me, but peptone by mouth seems an idle gesture. If I am incorrect will you kindly inform me as to my error?

F. GREGORY CONNELL, M.D., Oshkosh, Wis.

ANSWER—Peptone therapy in allergic conditions has been advocated for many years especially by French and German writers. The references are too numerous to list. In 1916, Pagniez and Vallery-Radot (*Etude physiopathologique et thérapeutique d'un cas d'urticaire géante, anaphylaxie et anti-anaphylaxie alimentaires, Presse med.* 24:529 [Nov. 23] 1916) stated that the feeding of small amounts of the specific foods before the regular meal tended to desensitize the individual temporarily to that food. Even the small amounts of the food, however, were capable of producing allergic reactions, as noted by Urbach and others. Subsequently many workers, such as Urbach, Loeb, Vallery-Radot and Eiselsberg, began to use the specific peptones on the ground that in this way they could obtain temporary desensitization without fear of allergic reactions. Even earlier, nonspecific peptones had been employed orally. In the latter procedure, whenever there was a desirable effect it was presumably due either to the coincidence that the patient was actually sensitive to the protein from which the peptone was prepared or that the peptone represented one of the allergens to which the individual was sensitive and the desensitization to one protected partially against the others.

While the scientific evidence justifies but little confidence in the efficacy of peptone either orally or parenterally, in the discussion of the treatment of angioneurotic edema the use of this substance was suggested only after other more rational methods had been tried.

CABBAGE AND GOITER

To the Editor—Is it positively proved that cabbage in any form is conducive to the formation of goiter? Also is boiled cabbage more likely to do this in case it is true? Again if true is it possible that a goiter already present will be increased by the eating of cabbage occasionally?

M.D., New Jersey

ANSWER—Chesney, Webster and Clawson (*Bull. Johns Hopkins Hosp.* 43:261 [Nov.] 1928) were the first to show that rabbits fed on cabbage as the principal food develop goiter within two or three months and that with continued feeding of cabbage the goiter may grow to large proportions. This work has been confirmed by many workers including Marine and Ivy.

It appears that cabbage grown in certain localities has goitrogenic properties that the goiter is of the simple or endemic type as seen in man and that feeding iodine prevents its development but induces intense intoxication with a high basal metabolic rate and death when administered to such animals after the goiter has appeared. At necropsy the goiter of such animals is of the hyperplastic type. Steaming cabbage for thirty minutes increases its goitrogenic properties.

It is believed that cabbage fed as the principal article of diet over long period produces goiter by exhausting the iodine reserve and inducing a sort of hyperthyroidism in the thyroid.

It is entirely unlikely that goiter already present in a patient would be influenced materially by the occasional eating of cabbage. In the experimental animal goiter is induced only on a diet, principally cabbage, eaten over a long period. Curiously enough, this type of goiter may also be induced experimentally by other foods than cabbage.

EPINEPHRINE WITH POLLEN ANTIGENS

To the Editor—Will you kindly tell if there is any method of administering hay fever antigen and a dose of epinephrine at the same time? I have a patient who has a relative who says she has had it that way. Please omit name.

M.D. New York

ANSWER—Epinephrine has been added to pollen antigens by many men in recent years and the two have been injected simultaneously. Epinephrine acts by slowing the speed of absorption of the pollen extracts and therefore causes local swelling rather than the uncomfortable and sometimes dangerous general reaction.

This method is, of course, most important in the more sensitive group of patients and it is in this group that the addition of epinephrine is indicated, if it is advisable at all. By this procedure the dosages of pollen extract can usually be safely raised with each injection. However, it is obvious that once started, epinephrine must not be stopped else severe reactions are apt to occur. Duke uses both a tourniquet and epinephrine with his injections so as to lessen still further the chance of a general reaction.

The use of epinephrine in this way has some decided disadvantages. Pain occurs with the injections and is usually marled and nervousness and palpitation are well known results of its use though not so severe when small amounts of epinephrine are used. A great drawback lies in the fact that epinephrine when used over long periods tends to bring about a diminution in its effectiveness. The patient derives less and less advantage from its use. Unfortunately too these individuals are often the ones who develop pollen asthma which may be so severe as to demand the injection of epinephrine. If the patient has already been given this drug over long periods he will probably fail to obtain relief at the time when he most needs it. And lastly it is not known how harmful the continued use of epinephrine is. It is possible that long continued administration of the drug may be more injurious than is now believed.

For these reasons most specialists in this field do not add epinephrine to their injections of pollen extract. Instead they inject slowly and withdraw the needle a little so as to diminish the chance of an intravenous dose. The dosages are increased cautiously and never more than 50 per cent at a time. Local reactions call for repeated injections of the same amount until no soreness results and then amounts are increased slowly. A local reaction is a danger sign—if the next amount is stronger, disaster in the shape of asthma, hay fever or urticaria may ensue. In view of the enormous number of pollen extract injections, the percentage of fatalities is extremely small.

BURNING SENSATION ON PICKLING PEPPERS

To the Editor—For the past several days women have been coming to the emergency hospital complaining of severe burning sensations of their hands following the pickling of red or green peppers. Many of the women state that this is the first time they have experienced this condition although they have been pickling peppers for years. On examination of the hands no definite pathologic picture is presented—there is no redness, swelling or increase in heat—merely the patient's statement of extreme burning. Because of this picture a diagnosis of dermatitis due to pickling peppers has been made instead of dermatitis venenosa. I have tried treating these cases with equal parts of glycerin and alcohol similar to treating frost bites. This has proved unsatisfactory, the burning sensation persisting for hours after the application of the solution. Can you please explain the cause, what the proper diagnosis should be and if there is a specific treatment? Is there any literature? Kindly omit name.

M.D. Milwaukee

ANSWER—There has been found in the literature no reference to a burning sensation in pepper picklers. One housewife has, however, reported a temporary dermatitis of hands and face after cutting up fresh sweet peppers and such cases are probably common, though not reported. Sweet peppers are a variety of capsicum, as is red pepper, which was formerly used in medicine as a counterirritant. The fact cited that the picklers have never before experienced this sensation of burning may be explained by assuming a difference in the variety of pepper grown this year or if the same variety was used some difference in the method of cultivation or in the season which has made them more pungent. Or there may be some difference in the other ingredients of the pickle most of which can be

classified as irritants. On the other hand, the picklers may have perspired more freely during the handling of the peppers, thus dissolving more of the irritant and rendering the skin more susceptible.

The particular irritant responsible for the burning sensation might be discovered by making patch tests. A very small cotton pledget soaked in the vinegar used is placed on the skin of one of the susceptible workers covered with a patch of oiled paper, oiled silk, gutta percha or sheet rubber fastened with adhesive, and left in place for a few hours. Small pieces of pepper, the cut surface next to the skin, should be fastened on in the same way, the different tests being placed wide apart so that the burning sensation can be located. The tests should be of short duration, removed as soon as the sensation is distinctly felt. The risk of causing a patch of dermatitis should be taken into consideration.

Thorough washing with hot water and soap as soon as the working hours are over ought to be the best protection against the burning, though enough of the irritant may have been absorbed during the work to cause the sensation after work in spite of thorough removal of the remainder. The use of rubber gloves or of forceps for handling the irritating substance would protect. A lotion composed of 50 per cent or stronger alcohol containing 1 per cent menthol might be helpful in counteracting the burning sensation. An appropriate name for the condition would be pepper picklers' pruritus.

USE OF TRIBROMETHANOL IN PARKINSONIAN SYNDROME

In answer to a query on this subject (THE JOURNAL, September 23, p. 1021) the statement was made that "tribrom ethanol has been employed as a sedative in agitative mental crises in which it has been used in the form of the commercial 25 per cent solution in doses of 0.1 Gm., repeated if necessary two or three times a day."

This statement was in error, since the dosage is always stated as milligrams per kilogram of body weight. One hundred milligrams per kilogram is at or near the upper limit of dosage for basal anesthesia and would provide complete surgical anesthesia in some cases. Such a dosage has been used to control convulsions in tetanus but the recommendation for repetition of this large dose several times a day is hardly warranted without proper qualification. It would usually be quite unnecessary and even dangerous to repeat the full dose. Certainly 100 mg. per kilogram cannot be considered a "sedative" dose for use in Parkinson's syndrome. The solution is given rectally and the 25 per cent dilution is made from the commercial solution which is 100 per cent (weight/volume) in amylene hydrate.

UNIATRAL ATROPHY OF THE BREAST

To the Editor—In THE JOURNAL September 30 page 1098 appeared a query on unilateral atrophy of the breast. A little elucidation may here be advisable. In doing physical examinations of the chest one frequently encounters some of the stigmas of tuberculosis and atrophy of the mammae and of the nipples is often diagnosed as a symptom of tuberculous disease. In the male the nipple is found in the fourth interspace generally, but with contraction of the chest subsequent to pulmonary tuberculous disease the nipple may be greatly displaced. The breast in the female modifies conditions depending on the size and here usually one finds that the breast on the affected side is smaller and less developed than the breast over the still healthy side. Here the nipple itself is smaller and less normally developed and the areola is also smaller and less pigmented over the affected side. In the case quoted of a woman aged 23 after a thorough chest examination a Mantoux test should be given with 1 mg. of old tuberculin. This if positive is followed by a careful examination of the right side of the chest and by a roentgenogram. This will clear up the problem as one of right sided chronic slowly developing pulmonary tuberculosis when pulmonary tuberculosis was never suspected. Many cases of slowly developing latent or hidden pulmonary tuberculosis with good resistance and with little or no fever and no pulse accentuation belong in this category.

JOHN RITTER, M.D. Miami Fla.

HABITUAL ABORTION

To the Editor—In THE JOURNAL October 7 a correspondent requests information as to the cause of habitual abortion. It might be wise to call to his attention that undulant fever is a possible cause. I have one patient who aborted twice in whom I subsequently diagnosed undulant fever by means of the well known agglutination test. In the first instance there was a large area of calcification in the placenta and in the second the placenta was studded with necrotic areas full of decomposed blood clot. In neither instance was the organism *Alcaligenes abortus* isolated from the placenta since the condition was not suspected. However other cases are on record in which the abortion was proved to be due to *Alcaligenes abortus* infection.

LICENSING OF GRADUATES OF FOREIGN MEDICAL SCHOOLS

In February, 1933 at a meeting of representatives of the Federation of State Medical Boards of the United States, the New York Board of Regents the National Board of Medical Examiners, the Council on Medical Education and Hospitals of the American Medical Association and the Association of American Medical Colleges, a committee was appointed to deal with the problem of graduates of European medical schools who may apply for licensure in the United States. The committee consisted of Dr Harold Rypins, chairman Dr Walter L Biering, Dr William D Cutter Dr Fred C Zapffe and Dr Willard C Rappleye. During the year members of the committee have held conferences with Dr Edouard Rist representing the French government, Dr Georg Kartzke representing the German ministry of education and Dr Robert Alessandri representing Italy. A report of the committee was presented to the Association of American Medical Colleges meeting in Minneapolis, October 31. The committee reports as follows

1 The number of native-born Europeans applying for admission to the medical licensing examinations in the United States is annually diminishing and the examinations appear to be serving as a barrier against the licensure of the incompetent

2 At the present time the only European countries in which American medical students matriculating after March 1 1933 will on the completion of their studies be eligible for admission to American medical licensing examinations are Italy and the British Isles

3 There has been established a voluntary method for selecting and restricting American students for admission to the study of medicine in Italy, which is eminently satisfactory and should serve as a model for agreements with other European countries

4 The joint action of the Federation of State Medical Boards of the United States the Council on Medical Education and Hospitals of the American Medical Association the Association of American Medical Colleges and the National Board of Medical Examiners has definitely decreased the number and improved the quality of American students studying medicine in Europe. It has undoubtedly raised the prestige of American

medicine in Europe and will raise the reputation of European medical faculties throughout the United States and result in a mutual understanding between the medical profession in this country and in Europe

The committee further recommends

1 That no action be taken in reference to the admission of native-born Europeans for admission to American medical licensing examinations and that, so far as is consistent with the maintenance of high educational and professional standards, physicians who are victims of racial and religious persecution in Germany be permitted the privilege of practicing medicine in the United States

2 That the voluntary method of selecting in this country students for admission to Italian medical schools serve as a model for similar agreements with other European countries and that a committee be appointed to advise and assist European authorities in reference to the selection of American students

3 That the committee be continued with authority to carry on further negotiations with the various European authorities looking toward a proper selection and restriction of American students in Europe

The committee also expressed its appreciation of the valuable cooperation of Prof William C MacTavish of New York University and of the sympathetic understanding of this problem by the representatives of the various European countries

Georgia June Report

Mr R C Coleman, joint-secretary, State Examining Boards, reports the written examination held by the Georgia State Board of Medical Examiners at Atlanta, June 14-15, 1933. The examination covered 10 subjects and included 100 questions. An average of 80 per cent was required to pass. Eighty-five candidates were examined, all of whom passed. Five physicians were licensed by reciprocity. The following colleges were represented

Book Notices

Tuberculous Bacillæmia By C. S. Wilson. With appendices and notes by Herin Schwabacher, C. C. Okell and F. A. Wood. Medical Research Council Special Report Series No. 182. Paper. Price 2s. 6d. Pp. 116 with illustrations. London: His Majesty's Stationery Office, 1933.

Within the last few years numerous excellent critical reviews accompanied by sound experimental investigation of the problem concerned have appeared under the auspices of the Tuberculosis Committee of the Medical Research Council in Great Britain. Dr. Wilson's monograph conforms to the high standard set by previous publications. The numerous reports of tuberculous bacillæmia emanating from central Europe at the present time, based on the views and technique of Lowenstein, have formed a highly puzzling chapter in tuberculosis investigation. Tuberculous bacillæmia has been reported as extremely frequent in all forms of tuberculosis, but in addition its existence has been recorded by Lowenstein and others as common in rheumatism, arthritis, chorea and a variety of diseases of the nervous system which have accordingly been considered by these investigators as hitherto unsuspected forms of tubercle bacillus disease. During the last few years much opposed evidence has also accumulated. Wilson has summarized the evidence for both sides and evaluated it in a thoroughly sane way. His criticism casts grave doubt on the reliability of much of the evidence recorded for bacillæmia in the diseases named. In the monograph a large number of sources of error are pointed out to which it is clear that many of those reporting positive results have not paid sufficient attention. Readers cannot fail to be impressed by the soundness of his presentation. As appendices to the monograph Drs. Schwabacher, Okell and Wood have reported carefully controlled experimental investigations of their own on the subject which completely fail to bear out the contention of frequent tuberculous bacillæmia in visceral tuberculosis and the other diseases named. On the other hand, Dr. Schwabacher's results indicate that only by rigid technique can certain sources of error leading to false positive results be excluded. The general conclusion of the authors is that technical errors are responsible for a high percentage of the cases of bacillæmia reported.

The Essential Psychoses and Their Fundamental Syndromes By Dom Thomas Verner Moore, Ph.D., M.D. Volume III, Number 3, *Studies in Psychology and Psychiatry from the Catholic University of America*. Edited by Edward A. Pace, Professor of Philosophy. Paper. Pp. 128. Baltimore: The Williams & Wilkins Company, 1933.

This is an ingenious attempt at assembling the symptoms of psychoses into fundamental syndromes through the application of a mathematical method of association or correlation. After selection and definition of the separate symptoms observed in the essential psychoses (dementia præcox and manic-depressive conditions) a tetrachoric method of intercorrelating symptoms was adopted instead of the purely empirical grouping of these symptoms into syndromes, and the syndromes were determined by mathematical incidence of the symptoms. Those interested in the details of applying Spearman's tetrad function to determine the underlying common factors in a table of variables can find a description of the method in the reference given in the footnotes in Dr. Moore's book. Twenty-six of the symptoms noted in a group of 402 psychotic patients have been defined and grouped under the four headings of general cognitive, emotional and volitional. In the final study, cases of only 367 of the patients were used in obtaining the intercorrelations of the symptoms. Naturally, a work attempting an approach of this sort will not prove easy reading. Some knowledge of mathematical functions and methods is essential, and the reader must be grounded in clinical psychiatry. As has been stated, the symptoms of the psychoses have been chosen from the dementia præcox and manic-depressive groups. After the application of Dr. Moore's method five syndromes are erected out of the twenty-six basic symptoms displayed by the patients studied. Four of the syndromes which are termed the catatonic syndrome, the deluded and hallucinated syndrome, the constitutional hereditary depression syndrome and the retarded depression syndrome are more or less familiar as clinical entities under somewhat different terminology. The

fifth syndrome is termed by Dr. Moore paranoia irritabilis. He states that the cardinal syndrome underlying this condition is that of paranoid irritability and that it consists of four specific symptoms—irritability, tendency to tantrums, destructiveness, and euphoria. There is a tendency of paranoia irritabilis to combine with other symptoms of psychosis. This book will hardly be used by the medical student or by the general practitioner. To the psychiatrist it presents a departure from the usual method of classifying symptoms. The symptoms selected as a basis for this study are well defined in the text.

Les révelés de la tuberculose pulmonaire chez l'adulte. Conditions de leur polymorphisme anatomo-clinique. Par le professeur Emile Sergent. Papier. Price 4 francs. Pp. 226 with 38 illustrations. Paris: Masson & Co, 1933.

In this work the author has given a brilliant clinical interpretation of the reactivation of tuberculosis in the adult. In places it is highly speculative. Nevertheless it is a fascinating work and convincing even where the issues may be bridged with scant evidence. It consists of a collection of lectures fitted together and given a general title. It contains the author's theories representing well the French school, supplemented by serial roentgenograms. One cannot read this book without obtaining clearer views on the complex subject of reactivation.

The first chapter is a lecture devoted to the clinical evolution of the disease and the second to the problem of reactivation. Each serves as an outline for the last three chapters which elaborate interestingly on three phases of reactivation: the soil, the seed and the routes of reactivation.

Perhaps the greatest worth of the volume is in reemphasizing the role of the host in the disease. The author considers the soil of tuberculosis little different from the soil for wheat farming or for the oaks in Fontainebleau where many acorns fall but few produce oak trees.

First, the host is divided into two great divisions of virgin soil and tuberculized soil. Only the tuberculized soil is concerned in the subject under discussion. The difference of the two is explained by the classic Koch phenomenon' (supplemented by the work of Roemer and Debre) wherein the host undergoes a change of reactivity as a result of and during a tuberculous infection. This 'allergy' or lack of it is the fundamental difference. Then the author brings in almost an innumerable set of minor factors that bear on the infection and its course: age, race, sex, puberty, pregnancy, other diseases, accidents, trauma and many other conditions that change the soil from a resistant one to a good culture medium. Slight temporary chemical changes may permit the growth of a tubercle bacillus that would otherwise be eliminated or die out. Certain tissues, for example, will rarely ever permit tubercle bacilli to grow (muscle, pancreas), others rarely, while others are good soil. Now these tissues are not only modified by allergy but all the vicissitudes of the human body during life also enhance or depress the growth of the parasites that chance to localize in them. The symptomless lesion that contains living bacilli 'buried alive' he considers active but the lesion in exacerbation he calls an "active evolution" beginning with active clinical disease. From this, according to Sergent, it can be assumed that there would be three types of lesion: cured, active and active evolutive'. The active lesion, he thinks, elaborates a filtrable virus through the capsule that may ultimately cause a spread of the disease. There are, perhaps, some workers who would take exception to the liberal use of activity. Large numbers of primary tubercles bury the bacilli alive and they stay buried until they die out without producing disease at all. These could properly be called encapsulated and healing rather than active.

In the second section the author considers the parasite. Tubercle bacilli like all living beings have peculiar and variable affinities that govern largely its localizations and resulting infections. Some bacilli, he thinks, are inert and are thrown out without any effect on the host; others are active and may localize if the opportunity presents itself. The extensive polymorphism of clinical tuberculosis, however, is explained largely on the basis of a variable parasite. Not only does the parasite vary from strain to strain but each bacillus varies in its growth and action. Particularly does he stress the effect of the filtra-

ble phase of the tubercle bacillus when the effect on the host is atypical. He is not as extreme as Calmette in setting apart a separate "ultravirus disease," but he does believe in an overlapping of virus and bacillus, producing a heterogeneous type of parasite that causes much of the variability in clinical manifestations.

He explains many obscure clinical phenomena as a result of the filtrable phase. The condition in one patient simulated asthma but ultimately was found to be tuberculosis. The early obscurity he thought was due to filtrable forms, because by filtering the sputum they obtained an atypical tuberculosis in animals whereas there were no bacilli found in the sputum until long afterward, when an "evolutionary attack" appeared that was typically tuberculous. The lesion of the virus, he states, is not caseous and there is no primary focus ever produced. Cessation comes only with the bacilli. Many other conditions are reported to be due to the virus, such as rheumatoid arthritis, erythema nodosum and certain types of tuberculous pneumonia. The results, however, are not constant, because when the virus comes back to the bacillary phase many new strains of bacilli are created that vary from one to another.

There is no denying now that filtrable forms of tubercle bacilli exist, that they are infectious and that they are a factor in the disease, but the author's free interpretation of atypical clinical signs in terms of the yet rather meager evidence of filtrable forms in such cases must be considered for the present only theory. For example, free microscopically visible granules may account for all the phenomena without invoking the ultra-microscopic forms at all, non-acid fast forms may also escape detection and play a part instead of the virus. The extent of the role of the pleomorphic forms of tubercle bacilli is yet undetermined and can be made out only by long and careful bacteriologic study.

The routes of reactivation are given with an excusable bias in favor of the author's theories of lymphatic spread. As interesting as his ideas are relative to the reactivation of old foci in the parenchyma and the hilar lymph nodes by lymphatic spread, both with and against the normal current, the extent of each mode of spread is still undetermined. Little stress is placed on the direct rupture of old foci into the bronchi or endobronchial spread by a penetration into the bronchi or by hematogenous spread, well represented by the recent German school of teaching. It is true perhaps that some must start in the perifocal lymphatics, but they are not necessarily confined there long. Both the blood and the bronchial channels may be penetrated easily and early and cannot well be left out of such a work. The rather direct route from the cervical lymphatics to the lungs needs further confirmation, and the diagnosis of 'peribronchitis' by the x-rays alone would be difficult. Those who follow the evolution of tuberculous lesions to the necropsy room find that many shadows are overlooked on antemortem roentgenograms and that many shadows which are present are of little or no significance. Much remains to be done in the pathologic interpretation of roentgenograms.

In spite of or, in fact on account of much controversial matter, the book is highly recommended to everybody engaged in tuberculosis work, especially those interested in the subject from an epidemiologic and clinical standpoint. It may be justly represented as a potent stimulant to creative thinking in tuberculosis as well as a work that is composed principally of good teaching that will endure.

Teaching Methods in Medicine. The Application of the Philosophy of Contemporary Education to Medical Schools. By William Duncan Reid. M.D. F.A.C.P. Assistant Professor of Cardiology, Boston University School of Medicine. Cloth. Price \$1. Pp. 111. Boston. The Author, 1933.

Many clinical teachers of medicine admittedly understand but little of pedagogy. This small volume attempts to describe as simply as possible certain fundamental pedagogic methods now used by modern teachers in other fields of instruction and to arouse the interest of clinical teachers in the broad problems of education. The author begins with the argument that at present no formal teacher training is necessary for teachers of medicine and therefore that their teaching is apt to be conducted in more or less haphazard fashion and in a manner not strikingly successful. He describes briefly various teaching methods employed in progressive schools and colleges and

attempts to show how these methods might be utilized or modified to improve medical teaching. He gives a number of good references to the current literature on education, urges doctors who are instructing medical students to study seriously how to teach and suggests, finally, that a useful development in the scheme of medical education well might be to bring it into line with the philosophy of education now existing in the public schools. On the whole, this book makes a gallant effort to be stimulating and of practical interest to teachers of medicine. As a pioneer effort, it deserves sympathetic commendation.

The Anatomy of the Human Skeleton. By J. Ernest Frazer. D.Sc. F.R.C.S. Professor of Anatomy in the University of London. Third edition. Cloth. Price 28s. Pp. 292 with 219 illustrations. London: J. & A. Churchill, 1933.

The most important addition to Frazer's fine contribution to the subject of anatomy of the human bones and joints and their muscles is a description of ossification in individual bones. He advises those who wish to study the skeleton not to confine their attention to the bones but to consider also the cartilage, ligaments and joints that are concerned in maintaining the form of the body and in enabling it to move about. He divides the skeleton into the appendicular skeleton of the limbs, the axial skeleton of the trunk and the skull. Bones do not take shape as such *ab initio* but are preformed in the embryo as condensations of mesenchyme, which in most cases become cartilaginous before ossification commences in them but in some remain unchondrified. In the former case the bones are formed in cartilages, and in the latter they are formed in membrane. These terms mean that the bones have replaced cartilage or noncartilaginous membrane, as the case may be. The process of ossification is essentially similar in the two varieties of formation except that in chondral ossification the cartilage is calcified first and then absorbed and replaced by the true bony formation. Certain large cells called osteoblasts have the power of depositing or forming bone around themselves; they exist in the covering tissues of the developing bone (periosteum or perichondrium) and, in the case of chondral ossification, grow into the cartilage and occupy the spaces made by the confluence of the cell spaces that goes with calcification. The early bone thus formed is removed by the action of other cells known as osteoclasts, and in this way a medullary cavity is provided in long bones while additional bone is being laid down on the surface under the periosteum, so that the bone increases in thickness. Thus there is no direct ossification of cartilage but a replacement of it by bone that is made in the same way as in membrane bones. This book is a virtual encyclopedia of the subject considered, and students should so regard it. It is not elementary or written for those who try to grasp the subject in a hurry. The illustrations, which are chiefly diagrammatic, are excellent. Many are in color. In reading this book the greatest benefit can be derived if the student has dried specimens of bones before him and refers to them continually.

Dietetics for the Clinician. By Milton Arlenden Bridges. B.S. M.D. F.A.C.P. Associate in Medicine at the New York Post Graduate Medical School, Columbia University. In collaboration with Ruth Lathrop Gallup Dietitian. Foreword by Herman O. Mosenthal. A.B. M.D. Director of Medicine at the New York Post Graduate Medical School, Columbia University. Cloth. Price \$6.50. Pp. 666. Philadelphia: Lea & Febiger, 1933.

This volume follows the usual routine of dietetic textbooks, proceeding from a review of normal digestion food requirements and food classifications through the dietetic therapy of disease, infant feeding and diseases of childhood to a comprehensive appendix of recipes and statistical tables. The majority of the chapters have been compiled by the author, others having been left in the hands of his colleagues who are specialists in various fields. While the pathologic and dietetic aspects of the subjects are well handled the book excels in its purpose as a thorough reference work. It is liberally filled with practical diet outlines, food tables and recipes particularly helpful to the practitioner who unfortunately is frequently expected to be both menu designer and ready reference cookbook for his patients. In fact one does not encounter in one volume as complete a list of food tables as is found here. Attention may be called to the thoroughness of the less usual tables such as those covering foods highest in oxalic acid, foods capable of increasing uric acid and purine free foods.

Medicolegal

Insurance Loss of Use of Arm by Surgeon—The defendant insurance company insured the plaintiff, a physician and surgeon, against "dismemberment or complete and permanent loss of use of limb." By reason of paralysis agitans, affecting his right arm, the plaintiff became unable to operate with a knife. He sued on the policy, and when the trial court directed a verdict for the insurance company he appealed to the United States circuit court of appeals, seventh circuit. The question on appeal was whether, within the meaning of the policy, the insured physician had completely and permanently lost the use of his right hand or arm as the result of disease, *with reference to the occupation in which he was engaged when he was insured*. The plaintiff physician contended that the policy insured him as an operative surgeon, that he was a practitioner of medicine only as an incident to his operative surgery, and that his right to insurance benefits as an operative surgeon, because of the loss of the use of his right hand and arm, was not defeated by the fact that he could still use them in the practice of medicine. The use of the arm and hand, he contended, was completely and permanently lost for all practical purposes in the occupation with reference to which he was insured.

The policy, said the circuit court of appeals, insured the plaintiff as a physician and surgeon. Ninety-five per cent of his work may have been surgery when the policy was issued, but if so, that fact formed no part of the contract and there was no evidence that the insurance company knew it when the contract was made. The evidence showed that since the plaintiff's illness occurred he did everything in the practice of his profession that he did before, with the exception of using the knife in operations. In doing those things he used his right hand and arm, not perhaps as well or with as much ease as he formerly did, but certainly in such manner and extent as to constitute some actual practical use of his right arm and hand in the pursuit of his profession. The fact that the plaintiff has sustained a very great and serious loss in the use of his right arm and hand and that that loss is permanent is not determinative however of his right to recover in this action. The burden of proof was on him to show that no actual practical use of his hand and arm as a physician and surgeon remained, and in that proof he failed. The evidence was not conflicting, said the court, and if the case had been submitted to a jury and the jury had returned a verdict for the physician, there would have been no evidence in the record to support the verdict. There was no error committed, therefore, when the trial court directed a verdict for the insurance company. The judgment of the trial court was affirmed.—*Beck v Zurich General Accident & Liability Ins Co* 62 Fed (2d) 965

Eugenic Sterilization Statute Constitutional—The sexual sterilization of inmates of state institutions for the insane who are afflicted with hereditary, recurrent forms of insanity, idiocy, imbecility, feeble-mindedness or epilepsy is authorized by article 3 chapter 26, Session Laws, Oklahoma, 1931. Mam, an inmate of the Central Oklahoma State Hospital for the Insane, came within this class. The State Board of Public Affairs, complying scrupulously with the provisions of the statute, ordered him sterilized. Its order was affirmed by the district court, Oklahoma county. Mam by his guardian, appealed to the Supreme Court of Oklahoma.

On Mam's behalf it was contended that the district court erred in finding that the proposed vasectomy would be without detriment to Mam's general health. The physicians who testified that such an operation would be beneficial, rather than detrimental, it was argued, had never performed such an operation. But, said the Supreme Court, learned and scientific men can virtually know things without having experienced them and the opinion of these physicians is confirmed by *Buck v Bell* 143 Va 310 130 S E 516 where it was said:

"These operations do not impair the general health or affect the mental or moral status of the patient or interfere with his or her sexual desires or enjoyment. They simply prevent reproduction. In the hands of a skilled surgeon they are 100 per cent successful in results."

So too in *Smith v Command Wayne Probate Judge*, 231 Mich. 409, 204 N W 140, it was said: "These operations are the least radical known to medical science." The record amply sustained the finding made both by the board and by the district court, that vasectomy would not injure Mam's general health.

It was next contended that the power conferred by the statute on the State Board of Public Affairs, an administrative body, is judicial in character and therefore under the state constitution could not be lawfully so conferred. The power so conferred, said the court, requires the administrative board to ascertain facts and to make a proper order on the basis of the facts so found. While the board's duties are to some extent judicial or quasi-judicial, yet a review and trial de novo before a judicial tribunal are authorized. Because of the review authorized, the trial de novo and the stay pending such review and trial, Mam was not injuriously affected by the grant of quasi-judicial powers on an administrative board. He has no concern therefore, with the grant of power to the board.

Mam's guardian next contended that the sterilization statute was contrary to the provision of the Oklahoma constitution, which prohibits the infliction of cruel or unusual punishments. The Supreme Court found however that there is no element of punishment involved in the sterilization of feeble-minded persons. In this respect sterilization is analogous to compulsory vaccination, both are nonpunitive. The constitutional prohibition of cruel or unusual punishment has no application to the surgical treatment of feeble-minded persons, for the constitutional prohibition has reference to punishment after conviction of crime. The record said the supreme court, affords uncontradicted evidence to support the view of the trial court that vasectomy is not cruel, inhuman, unreasonable or oppressive.

On behalf of Mam it was next contended that the act violates section 7, article 2 of the state constitution, which provides that no person shall be deprived of life, liberty, or property, without due process of law, "because 'it deprives a man of a part of his life, to wit the ability to produce life' or procreate. Assuming, said the Supreme Court, that the right to beget children is a natural and constitutional right yet this right cannot be extended beyond the common welfare. Under the police power, the state may impose reasonable restrictions on the natural and constitutional rights of its citizens. This statutory provision for sterilization of feeble-minded inmates of public institutions the court held, constitutes a reasonable restriction on such natural and constitutional rights.

A further objection urged against the act was that it violated section 2, article 2, of the state constitution, which provides that:

All persons have the inherent right to life, liberty, the pursuit of happiness and the enjoyment of the gains of their own industry.

This contention, continued the court, is without merit. As was said in *Buck v Bell* supra:

The public welfare may call upon the best citizens for their lives. It would be strange if it could not call upon those who already sap the strength of the state for these lesser sacrifices often not felt to be such by those concerned in order to prevent our being swamped with incompetence. It is better for all the world if instead of waiting to execute degenerate offspring for crime or to let them starve for their unhealthiness, society can prevent those who are manifestly unfit from continuing their kind. The principle that sustains compulsory vaccination is broad enough to cover cutting the fallopian tubes.

The order of the State Board of Public Affairs that Mam be sterilized was accordingly affirmed.—*In re Mam (Okla)*, 19 P (2d) 153

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to *THE JOURNAL* in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Anatomy, Philadelphia

53 1176 (July 15) 1933

- Handedness and Bimanual Dermatoglyphic Differences Stella M. Leche, New Orleans—p. 1
Renal Unit in Kidney of Vertebrates J. G. Edwards assisted by C. Schmitter Buffalo—p. 55
Hair Growth Study of Effect of Pregnancy on Activity of Follicle in Guinea Pig (*Cavia Cobaya*) Helen L. Dawson St. Louis—p. 89
Hypophysectomy in Pregnant Rat R. I. Pencharz and J. A. Long San Francisco—p. 117
Notes on Morphology of Chromophil Material of Nerve Cells and Its Relation to Nuclear Substances L. Einarson Baltimore—p. 141

American J. Obstetrics and Gynecology, St. Louis

26 1146 (July) 1933

- Pregnancy and Labor Complicated by Myomatous Tumors of Uterus R. E. Campbell Madison Wis.—p. 1
Effect of Extracts of Urine of Pregnant Women on Hyperplastic Endometrium H. H. Klingler and J. C. Burch, Nashville Tenn.—p. 17
Clinical Study of Four Hundred and Three Cases of Adenocarcinoma of the Ovary Papillary Cystadenoma Carcinomatous Cystadenoma and Solid Adenocarcinoma of the Ovary L. Mary Moench Rochester Minn.—p. 22
Blood Sugar Findings in Eclampsia and Preeclampsia I. A. Siegel and H. B. Wylie Baltimore—p. 29
Autotransplantation of Placenta to Anterior Chamber of the Eye and Its Effect on Lactation S. Litt Chicago—p. 37
Fallacies of Trichomonas Vaginalis Vaginitis I. Streptococci as Etiologic Agents H. C. Hesselstine Chicago—p. 46
New Concept of Mechanism of Vertex Engagement in Simple Flat Pelvis W. C. Stude and V. E. Scherman St. Louis—p. 54
Observations on Adynamic Ileus Report of Case E. A. Schumann and J. V. Misset Jr. Philadelphia—p. 59
Relationship Between Gynecology and Orthopedics A. Stein New York—p. 64
Importance of Establishing Conditioned Reflex Pregnancy—Syphilis in the Minds of the Medical Profession E. L. Reyes New York—p. 71
Occiputoposterior Position Review of Two Hundred and Five Cases W. H. Mast Pueblo Colo.—p. 74
Thyroidoxiosis in Its Relation to Pregnancy J. T. Wallace, New York—p. 77
Elephantiasis of the Vulva Analysis of Twenty Six Cases in Negro Women from the Records of Charity Hospital in New Orleans J. T. Witherspoon and Elizabeth M. McFetridge New Orleans—p. 84
Abdominal Cesarean Sections Analysis of Two Hundred and Twenty Cases E. D. Colvin Atlanta Ga.—p. 90
Primary Ovarian Pregnancy Report of Case with Decidual Reaction A. M. Young and G. M. Hawk Cleveland—p. 97
Carcinoma of Cervix in a Girl of Sixteen M. Glass Brooklyn—p. 104
Tubal Twins Case W. A. Jewett Brooklyn—p. 108
Kraurosis Vulvae G. Johnson Wilmington N. C.—p. 110
Combined Pregnancy H. D. Lafferty Philadelphia—p. 112
Traumatic Rupture of Liver and Kidney with Evisceration Complicating Pregnancy W. F. Cummil and T. A. Martin York Pa.—p. 113
Inexpensive Light for Delivery or Operating Rooms W. C. Danforth Evanston Ill.—p. 114
Epilepsy Associated with Ovarian Dysfunction Treated by Irradiation I. J. Kaplan New York—p. 116
Ophthalmitis of the New Born C. C. Weitzman Brooklyn—p. 117
Device for the Correction of Postpartum Uterine Atony E. L. Stone New Haven Conn.—p. 118
Acute Fibroid Degeneration with Complete Torion of the Uterus Case A. J. Heischer and J. I. Kusliner New York—p. 120

Trichomonas Vaginalis Vaginitis—Hesselstine presents a preliminary report of experimentation with the vaginal flagellate which indicates that the vaginal trichomonad live on bacteria and are possibly nonpathogenic. He describes the technique for the separation of the flagellates and bacteria by the washing and the micromanipulation methods. He draws the following conclusions from this study: 1. The pathogenicity of *Trichomonas vaginalis* Donne is still unproved. 2. Some of the fallacies of the arguments favoring pathogenicity of this trichomonad have been mentioned. 3. Experimental observations

indicate that *T. vaginalis* Donne is a scavenger and feeds on bacteria. 4. *T. vaginalis* Donne fails to grow in the medium used in the absence of bacteria. 5. Presumably, an abnormal vaginal flora, or the condition producing it, is a prerequisite for the invasion of the trichomonads. 6. A nonhemolytic streptococcus is capable of producing a "*trichomonas vaginitis*" in the absence of trichomonads.

American Journal of Syphilis, St. Louis

17 305 448 (July) 1933

Reversal of Blood Wassermann Reaction in Untreated Syphilis E. T. Hoterson, G. W. Morrow and R. O. Hawthorne Kankakee, Ill.—p. 392

Syphilis of Cerebellopontile Angle—Friedman and his associates present five cases in which there were phenomena referable to the seventh and eighth nerves together with homolateral cerebellar signs. There were definite signs of involvement of the fifth nerve in four. There were general cerebral symptoms such as headache, dizziness and vomiting. In four, the disks were normal, in one, the fundi showed papilledema and hemorrhages. In spite of clinical improvement, the damage to the eighth nerve persisted in all the patients. There was marked facial weakness of the peripheral type. Such definite facial weakness is an unusual observation in early cases of angle tumor. Moreover, the signs of involvement of the fifth nerve were much more conspicuous than those observed in cases of angle tumor in the early stage in which, as a rule, only anesthesia of the cornea on the ipsilateral side can be demonstrated. The authors emphasize the fact that the coarse vestibulocerebellar type of nystagmus was not observed in their patients. It has been ascribed by Marburg and others to pressure on the brain stem and is encountered in most angle tumors. In the differential diagnosis between this lesion and neoplasm of the cerebellopontile angle it would seem that the disappearance, under early and persistent antisyphilitic therapy, of the general and some of the local angle signs and symptoms is in favor of a syphilitic process. The positive serologic observations are of the greatest importance. The Wassermann reaction was positive in the blood in all patients. In four of them, serologic evidence of syphilis was present in the cerebrospinal fluid. This syndrome must not be confused with simple syphilis of the eighth nerve or the neural recurrences that come on as a result of inadequate treatment. In these conditions the lesion is usually limited to the eighth nerve especially the cochlear division and phenomena attributable to pathologic changes in the angle are absent. Active and persistent antisyphilitic treatment led to considerable improvement in three patients. The early recognition of this clinical entity is of practical importance because the prompt institution of antisyphilitic therapy yields good results.

Introduction of Arsphenamines into the Central Nervous System—Since the drugs of the epinephrine group are powerful though ephemeral dilators of the cerebral vessels in man and since the bulk of arsphenamine injected intravenously is deposited into the tissues in a few minutes Wittenberg thought that by using bath properly timed an increased amount of the arsphenamine could be introduced into the central nervous system. One should expect to find more or less in the cerebrospinal fluid after such treatment than in that of patients treated by the ordinary method provided of course, the meninges

ges of the patients are permeable to arsenic viz that the central nervous system is involved. The safety of this treatment was tested in properly chosen patients. The authors report on the small number of patients treated shows that the treatment is safe in properly selected cases and that a larger amount of arsenic is found in the cerebrospinal fluid following this modified form of treatment.

Takata Serum Reaction—Trinnenholz states that the Takata serum reaction is almost always positive in cases of advanced, definite parenchymatous liver damage e. g., cirrhosis of the liver. It is more frequently positive in cases of syphilis (15 per cent) than in other cases (3.5 per cent) (genito-urinary, dermatologic and medical cases) when a question of liver damage does not present itself. When the Takata test is positive in cases of syphilis, an association with liver damage is suggested. It is more frequently positive in cases of secondary syphilis (34 per cent) and seropositive latent syphilis (37 per cent) than in primary (14 per cent) and tertiary (14 per cent) syphilis. The author suggests that arsenical exanthema is more common in cases of syphilis with a positive Takata reaction than in syphilitic patients with a negative Takata reaction. The outcome of the Takata reaction bears no relation to the Wassermann or Venereal reactions. The Takata test is not infrequently positive in nonsyphilitic cases when other signs of liver damage or probable changes in the albumin-globulin ratio are present (arthrosis, nephrosis, pernicious anemia). The Takata serum reaction may be of diagnostic and prognostic aid in syphilitic dermatologic and medical cases.

Toxemias of Pregnancy. L. I. Breitstein and A. Bernstein. San Francisco.—p. 42.

Sterility—Loomis presents an analysis of the histories of 732 sterile women, of whom 473 were treated. Of these, 208 or 44 per cent became pregnant. The Rubin test was normal in 53 per cent and 13 per cent were dismissed because repeated efforts showed total closure of tubes. Repeated efforts produced partial or complete opening in 34 per cent of these women whose first examinations were unsatisfactory, and nearly 20 per cent of these women became pregnant. Normal spermatozoa were present in 53 per cent after coitus, 37 per cent were only fair, and 10 per cent showed complete aspermia.

giving a high proportion of responsibility in sterility to the male or relative infertility. Cervical stenosis and erosion were found in 42 per cent and 38 per cent, respectively. Both are amenable to office treatment. Endocrine dysfunction was present in 67 per cent, most of whom were treated with thyroid or preparations of the female sex hormone. Basal metabolism is not relied on alone in judging hypothyroidism. Of these patients, 35 per cent became pregnant. The incidence of toxemia is not higher than normal, but involuntary abortions occurred in 17 per cent.

General Principles of Radiation Therapy of Tumors. W. W. Wasson. Denver.—p. 257.
The Physician Looks at Himself. L. W. Frank. Denver.—p. 267.

Radiation Therapy of Tumors—Wasson presents the following points concerning radiation therapy of tumors: 1. There should be a careful examination of the patient with an analytic evaluation of the symptoms present. 2. There should be a judicious and never a contaminated removal of a section of the tumor for the microscopic diagnosis between inflammatory benign and malignant neoplasms. 3. In the preliminary examination, the amount and extent of metastases should be determined. It is nearly always the metastases that are fatal to the patient. 4. The degree of the malignant condition is of great importance in selecting the method of treatment—surgical or radiation therapy. It even governs the manipulation of the tumor during the preliminary examination. 5. In advanced cases of malignant disorders if any treatment at all is justifiable radiation therapy is nearly always the method of choice. The economic problem must be given special consideration in these cases. 6. If radiation therapy is selected as the method of choice, it should be applied by one especially qualified for the task. 7. The general management of the case should be under the direction of a radiologist, a surgeon and the attending physician. 8. Every radiologist should keep an active follow up list of his cases in which radiation therapy has been employed. 9. Pain following surgical or radiation treatment is usually the first warning signal of a return of the condition in either the primary tumor or its metastases.

Complement Fixation in Vaccinia and Variola—By the technic of complement fixation, Parker and Muckenfuss demonstrated a specific reaction between the virus of vaccinia and its immune serum. The reaction is influenced by the potency of the serum and the time allowed for fixation, and apparently many of the failures of other workers to demonstrate it have been due to the use of serum of insufficient activity or to too short a period of fixation. Active virus in the antigen is not necessary for fixation. Preparations which had been boiled or passed through a Berkefeld N candle, and in which no virus could be demonstrated, would still fix complement with immune serum although not in as great a dilution as before treatment. These results are probably comparable to those obtained by Craigie in his study of the antigens taking part in the flocculation reaction. Specific complement fixation in smallpox has also been demonstrated by using a specific antivaccinal rabbit serum and the fluid from the pustules of the disease. This has been made possible by the adaptation of the test to a small volume measuring the reagents in drops. Various materials from different cutaneous diseases and the vesicles of varicella have been tested, without false positive results. With vaccinia and variola the results have been uniformly positive when the material was collected before the thirteenth day of the eruption. Difficulty due to bacterial contamination has been avoided by the use of serum prepared against a bacteria free antigen. Serums from ten patients with variola were tested with partial or complete fixation in three. Complement fixation with a specific antivaccinal serum may be of assistance in the early diagnosis of smallpox.

Physiologic Effects of Fever Temperatures—Carpenter and his associates determined the thermal death time of fifteen strains of the gonococcus in vitro at fever temperatures of 39, 40, 41, 41.5 and 42 C (102.2, 104, 105.8, 106.7 and 107.6 F). Seven strains had been under cultivation for twelve years, one for ten years and the other seven were isolated from one to four months prior to the experiment. The resistance of the strains of gonococci examined to the fever temperatures was variable. The cultures that were isolated ten and twelve years ago had, on the average, a longer thermal death time than the recently isolated cultures. At 39 C there was little, if any, effect on the growth of the organism. At 40 C, about 99.7 per cent of the organisms were killed by an exposure of ten hours, while death of all the cells was not obtained at thirty hours in eight of the strains. At 41 C, 99 per cent of the gonococci were destroyed in from four to five hours, while death of all the organisms required from eleven to twenty-three hours. At 41.5 and 42 C, 99 per cent of the gonococci were rendered nonviable in two hours. The remainder were killed at 41.5 C in from seven to twenty hours, while at 42 C the thermal death time varied from five to fifteen hours. In all instances the recently isolated cultures, with the exception of one "old" strain, showed the least resistance to 41, 41.5 and 42 C. The in vitro thermal death time of the gonococcus is short enough at 41, 41.5 and 42 C to suggest artificially induced fever as a valuable aid in the treatment of disease due to this organism. It is doubtful whether complete sterilization by heat can be obtained always from a single artificially induced fever of a duration of five hours.

Dermatologic Test—Wolffe found that tissue extract, among many fractions, contains one, apparently a polypeptide, which produces a cutaneous reaction in many persons. Because of its constricting local action he has called this fraction the S, or stricture, substance. It is prepared in the following manner: Pancreas, kidney or any other tissue is extracted with a hydroalcoholic menstruum containing hydrochloric acid. The extract is neutralized with ammonium hydroxide and filtered. The filtrate is acidified and concentrated in vacuo. Ammonium sulphate is added to the clear concentrate, yielding a precipitate which contains the S constituent. This precipitate is extracted with alcohol, and any insulin is removed if pancreas is used. The solution is concentrated in vacuo and passed through a Berkefeld filter leaving a residue which contains most of the S substance. This residue is dissolved in an acid menstruum to give a 3 per cent solution. To perform the test 0.025 cc of the solution is injected subepidermally (not intradermally) by means of a 26 gage needle and a tuberculin syringe. A bleb is produced and in the center of it a purely white area appears. Histologically, the author has found this to be due to focal tissue changes. This usually develops in from three to five minutes after the injection and is considered a positive reaction provided it remains for more than twenty-four hours. A negative reaction is one that fails to show this characteristic white center if 0.025 cc is injected, or when it disappears in less than twenty-four hours. After testing over 500 normal persons and hospital patients the author was impressed with the fact that apparently the so called vagotonic or parasympathetic persons react characteristically to a small amount of S substance, such as 0.025 cc or even less.

Diverticulosis and Diverticulitis of the Colon—Wilkinson reviews the literature on the etiology, pathology and treatment and discusses a method of treatment of diverticulosis and of the milder cases of diverticulitis. It seems more logical to him to attempt to keep the stools formed, to attain one normal evacuation daily to prevent overactive peristalsis and to decrease intra-intestinal pressure. These aims are not always to be achieved but they can be approximated in all cases and, by carrying them out many threatening cases of diverticulitis can be made to quiet down. Rest in bed for the initial period of treatment usually two weeks is of the greatest value and cannot be ignored. The diet a bland low residue, nonirritating one, should have as a basis chiefly carbohydrate foods. At first it should contain no vegetables, fruits or fruit juices. All fluids and foods should be warm. Rectal impaction should be watched for by frequent rectal examinations and prevented by the rectal instillation of a few ounces of warm olive or corn oil. If the stool has reached the rectum this simple measure usually suffices to cause an adequate evacuation. If the patient

complains of an increase in abdominal pain or gas, a small enema (1 or 2 pints) of warm saline solution gives prompt relief. Of the fruit juices orange juice taken hot and diluted is usually the least irritating. This should not be given until the movements are well formed and are becoming regular. Tomato juice is poorly tolerated and is better omitted. All forms of spices and condiments, iced drinks, fresh fruits, the skins or seeds of fruits and vegetables and coarse bread should be forbidden. Medication by mouth is of little value. Tincture of belladonna, however, seems to alleviate the distress from gas and promote a more natural type of intestinal activity. All forms of purgatives, laxatives and even liquid petrolatum should be prohibited.

Treatment of Menstrual Disorders—Witherspoon treated twenty-five cases of functional disorders of menstruation by the injection of blood from pregnant donors. The technique that he employed was to withdraw 10 cc of venous blood from the cubital vein of a woman in the early months of pregnancy and to inject it immediately in the buttocks of the patient. The injections were given at weekly intervals when the treatment was indicated. From the hormone test described by Frank and Zondek 10 cc of venous pregnancy blood contains from 30 to 100 units of the anterior pituitary luteinizing factor and a variable amount of estrin. Therefore, 10 cc was chosen arbitrarily as the desired dosage because of the lack of local symptoms it produces when injected into the buttocks, and because Zondek has pointed out that small doses are safer when it is desired to bring about the normal processes of ovulation and luteinization, since there is danger, if too great luteinization takes place before ovulation can occur, that the ovum will be imprisoned within the luteinized follicle. The author divides his series of cases into four groups and discusses them separately: eight cases of menorrhagia and metrorrhagia, twelve of amenorrhea, three of primary dysmenorrhea and two of menopausal disturbances.

Transmission of Tularemia—Collins reports the case of a man, aged 33, who required medical treatment because of an infection following the bite of a cat. The patient gave a history of having been bitten on the index finger of the left hand by a 6 months old kitten, fourteen days previously. The abrasion became sore in three or four days and this was followed by a chill, fever, headache and general malaise. Since that time he has had several chills and continuous fever. At the time of examination he had an indolent ulcer on the index finger of the left hand. The epitrochlear gland showed evidence of supuration and the axillary glands were tender and swollen. An incision was made over the epitrochlear gland and drainage instituted. The only other treatment used consisted of hot local applications and general systemic measures. The patient made a slow but progressive recovery. At the time of the first examination a specimen of blood was taken which showed a positive agglutination with *Bacterium tularensis*. The cat was secured and a specimen of blood was taken from the heart. This specimen and another specimen of the patient's blood showed the patient's blood positive to *Bacterium tularensis* in a dilution of 1:1,280 and positive to *Alcaligenes abortus* in a dilution of 1:320. The cat's blood gave a positive agglutination to *Bacterium tularensis* in a dilution of 1:80 but was negative to *Alcaligenes abortus*. The author believes that this proves serologically that the cat may be a carrier to human beings.

Thrombosis of the Inferior Vena Cava and Necrosis
—Bunn reports a case of skin necrosis occurring in scarlet fever accompanied by thrombosis of the inferior vena cava. The patient is now (eleven years later) in good health, excepting that he has varicose ulcers on both ankles. There is deep scarring of the left hip and there are prominent veins on the abdomen. Canalization of the thrombus of the inferior vena cava was evidently fairly complete, for there is no marked edema of the legs and no retarded development. During the fall of 1928 a sluggish varicose ulcer developed on the left ankle and in 1932 another on the right ankle. It is difficult to keep these healed. The abdominal collateral venous circulation is still active, as evidenced by definite distention of these veins. The lateral veins of the abdomen have remained larger than the anterior, which sign helps to confirm the diagnosis of thrombosis of the vena cava. The author feels that this blocking must have occurred below the level of the renal veins, else the outcome would probably have been fatal. The possibility of a concomitant infection of scarlet fever and diphtheria must be considered in spite of a single negative throat culture. This impression was strengthened by the appearance of a paralysis of the soft palate, which is often seen in diphtheria. What influence the diphtheria antitoxin might have exerted in the production of the hemorrhagic condition cannot be stated. The author knows no method of proving this relationship. However, the patient had never had any serum previous to this illness and consequently could not have been sensitized.

Rocky Mountain Spotted Fever—Parker and Davis describe tests which show that the serums of guinea-pigs recovered from Rocky Mountain spotted fever have a degree of protective value against the virus of Sao Paulo exanthematic typhus that is essentially specific and that guinea pigs recovered from Rocky Mountain spotted fever have as high a degree of immunity against the virus of Sao Paulo typhus as they have against that of spotted fever. Thus far only two tests have been made to determine the degree of immunity of Sao Paulo typhus recovered guinea-pigs to Rocky Mountain spotted fever. In both instances the guinea pigs remained afebrile. The data together with the authors' previous observations suggest that Sao Paulo exanthematic typhus and Rocky Mountain spotted fever are immunologically identical.

Belated Serum Treatment of Diphtheria—Houle reports three cases of paralysis that developed in an epidemic of relatively few cases so mild in symptomatology as to escape the diagnosis of diphtheria. None of the patients had received original antitoxic treatment. Relatively late specific treatment with antitoxin produced gratifying rapid and a complete cure of the paralysis. The author infers that antitoxin is often given in inadequate quantities and for an inadequate period and that on the development of paralysis, antitoxin should again be administered, with a proper safeguard against sensitization. In one of the desperately ill patients treatment was begun approximately fifty days after the diphtheric inflammation, beginning with 5,000 units, followed by 10,000 and 10,000 and 6,000 units. In the meantime the patient became progressively weaker and a convergent strabismus developed. No improvement whatever was noted for eight days, after which date progress was rapid and continuous. About one month later the boy was walking. He was naturally weak, with persisting evidence of cardiac and renal impairment, but he had recovered full voice, vision, deglutition and respiration. Now, after a lapse of eight years, he is in perfect health. In another case, two weeks after apparent recovery, the patient developed paralysis of the palate and of both legs. 20,000 units of antitoxin produced complete recovery in the third week.

Granulopenia—Rheinheimer and Smith present a case of granulopenia the symptoms of which developed a few hours after a second injection of gold and sodium thiosulphate, which was used in the treatment of a chronic discoid lupus erythematosus. There is no positive proof that the gold was responsible for the condition, but the history is suggestive of a causal relationship. The patient a woman aged 58 complained of red spots on the face which she had noticed for six months. Examination revealed the urine to be normal, red blood cells 4,500,000, white blood cells 8,000, neutrophils 72 per cent, small lymphocytes 24 per cent, large lymphocytes 3 per cent, eosinophils 1 per cent and hemoglobin 90. The patient was given 40 mg of gold and sodium thiosulphate intravenously. This was well tolerated. Six days later, a second similar injection was given. An hour after the ingestion of ice cream, the patient became nauseated and vomited. During the same night she had a chill lasting two hours and followed by high temperature. The following day a generalized erythematous rash appeared accompanied by slight swelling of the hands and feet but no pain. She was thought to have a gold reaction and was given sodium thiosulphate intravenously. This was repeated after two days. In four days the rash had faded and the temperature was normal. The next day she had a severe chill followed by high fever and profuse sweating. A deep erythematous rash appeared over the entire body. The hands, feet and face became swollen. At this time the temperature was 104.1, pulse 104, respiration 18, red blood cells 4,500,000, white blood cells 3,500, neutrophils 52 per cent, small lymphocytes 55 per cent, large lymphocytes 10 and nuclear index 3. The following day the patient was extremely weak and complained of severe pains in all the joints. The tongue, oral cavity and pharynx were deeply congested. The gum, inner surfaces of the cheeks, uvula and anterior pillars were covered with patchy curdled milklike flakes resembling thrush. The temperature remained high. On this day injective is given daily of 10 cc of a nuchal vaccine were started. In a few days later the patient had no improvement. Recovery hereafter is uncertain and the

patient has remained well to the present time. During the course of the illness the urine, blood culture and Wassermann test were negative.

Fractures of the Os Calcis—In fractures of the os calcis Funsten insists on a roentgenogram taken from an angle of 45 degrees, through the posterior aspect of the foot showing a projection of the lateral surfaces of the os calcis. In addition anterior-posterior and lateral views are made. In the interpretation of these roentgenograms an attempt is made to determine whether there is an upward displacement of the posterior fragment, a lateral displacement of the fragments or an involvement of the subastragloid joint, and whether there is involvement of the calcaneocuboid joint. If any of these conditions is present operative treatment is indicated in which instance a compression bandage is applied to reduce the swelling. The patient is allowed to remain quiet in bed for a period of about one week, thereby giving time for tissue reactions. After this the achilles tendon is lengthened by open exposure. The sliding method of lengthening has been the author's choice. Care should be taken that lengthening does not exceed three-fourths inch. This reduces resistance when upward displacement of the distal fragment of the os calcis is corrected and reflexly inhibits the action of the gastrocnemius during convalescence. The wound is closed with number 1 plain catgut. The foot is turned so that the inner malleolus is against a sandbag. An ordinary 3 inch rolled bandage is then placed in a curved position under the external malleolus and the fragments are impacted with a mallet. Next, a nick is made through the skin just anterior to the attachment of the achilles tendon superior to the border of the os calcis, on the outer side of the foot. Through this a number 24 urethral sound is passed to the inner side in which a small incision is made to allow the point to come through over the upper surface of the os calcis. With the toes against the table and with a lever board between the surgeon's chest and the arch of the foot traction is placed on the sound in such a way as to bring the posterior portion of the os calcis down into its normal position restoring the arch of the foot. If lateral impaction is not complete following the restoration of the posterior fragment of the os calcis reimpaction is done. The sound is then removed, a suture is placed in each wound and a cast is applied including the bandage under the external malleolus to maintain impaction of the lateral fragments. Two pieces of felt are placed in the arch and traction is made downward on the heel and toes. To insure proper arching the lever board is pressed into the arch while the plaster is hardening. The cast is allowed to remain for six weeks when it is divided and motion in the joints begun. Weight bearing is started at ten weeks when the support of the cast is supplemented by a high felt arch support. Thomas heel and single upright brace to prevent strain on lateral motion. The disability has been greatly reduced in the author's fifty-two cases in which he used this procedure.

Renal and Ureteral Calculi—Freshman presents a case of continuous stone formation in the urinary tract which illustrates the enormous size that may be obtained by calculi before giving rise to symptoms severe enough to induce the patient to seek relief. The patient underwent six operations during a period of nine years, on seven occasions he was relieved of a calculus or calculi under general anesthesia and once the calculus was voided spontaneously. None of the stones had a core of pure uric acid which might have accounted for their existence some time before becoming opaque to the rays. Fifteen months after his last operation the patient is in excellent health and on roentgen examination his right kidney appears to be free of stones. Intravenous pyelography shows good excretion in five minutes and almost normally shaped pelvis and calices.

Mesenteric Cyst—Steel states that it is usually during a laparotomy for some other condition that the presence of a mesenteric cyst is noted. Rarely do these cysts assume such a prominent position as to become the reason for operation, either in virtue of their size or because of some complication. The author reports the case of a girl aged 7 in whom such an operation was necessary. The abdomen was opened under spinal anesthesia by a right paramedian incision. Distended loops of small intestine were at once displaced. The seat of obstruction was found in the ileum about two feet from the cecum. Numerous cysts were present throughout the mesentery. One large cyst had kinked and dragged its weight across the ileum leading to complete obstruction. The cyst and mesentery together with two or three inches of intestine on each side of the cyst were resected and a lateral anastomosis was performed. The abdomen was closed without drainage. The patient made an uneventful recovery. Intestinal obstruction may arise in various ways dependent on the size, position and mobility of the cysts and their situation in the mesentery. The resulting acute obstruction is purely mechanical and is brought about by direct pressure or traction on the intestine while the occlusion may be completed by adhesions or kinks or, in rare instances, by volvulus of the intestine. The condition may be considered or suggested by the history, by isolating a mobile cyst, or by the pain, vomiting, diarrhea or constipation that arise from the pressure of the cyst. The diagnosis even in uncomplicated cases is difficult, but in the presence of intestinal obstruction an accurate diagnosis is practically impossible.

- *Malaria Due to Plasmodium Ovale Stephens 1922 Case N H Farley—p 101

Dermatitis Following Toxoid-Antitoxin—Chesney presents a case of exfoliating dermatitis, which occurred in a girl of 16 following the injection of two doses of 1 cc of toxoid.

antitoxin given within a period of seven days. He believes that the dermatitis was related to the two injections, as the patient showed acute sensitivity to serum and to the products of metabolism of the diphtheria bacillus, which are found in toxoid, and which, in highly sensitive people, may cause unusually troublesome local or general reactions. Intradermal tests with serum peptone and veal infusion confirmed that the patient was unusually sensitive to serum and that the minute amount of serum in the original injection of 1 cc of toxoid-antitoxin had caused the dermatitis. There was no trace of asthma or any other symptoms of allergy in the previous history of the patient or of her family.

Posterior Fossa Compression Syndrome—Rogers describes a syndrome in which the patient collapses and respiration stops while the heart continues to beat vigorously. If nothing is done the heart soon ceases to beat, the patient previously becoming more and more cyanosed. A failure of the respiratory center evidently takes place, the cardiac center being apparently less vulnerable to the effects of sudden compression, the heart action continues. Artificial respiration results in the diminution of the cyanosis, and patients have been kept alive for ten or twelve hours while artificial respiration has been kept up, but as soon as this has flagged the cyanosis has increased, the heart has slowed, and, when artificial respiration has finally ceased, the patients die. The cause of the syndrome would appear to be the relative vulnerability to pressure of the respiratory as compared with the cardio-inhibitory center. The compression may be produced by hemorrhage into the posterior fossa or by an intracranial tumor or abscess and, in the latter instances, may result from edema in association with the lesion. This was apparently the mechanism in the case that the author reports. Recognition of the syndrome enabled him to relieve the condition and to deal subsequently with its cause, a cerebellar cystic glioma. He states that prompt radical treatment may relieve the sufferer. When in a case of raised intracranial tension—whether from hemorrhage, new growth or abscess—respiratory failure occurs prolonged efforts at artificial respiration should not be carried out but relief of medullary compression should be secured by an emergency decompression of the posterior fossa. Oxygen administered through an intratracheal catheter, as in his case, may enable the operation to be undertaken but failing this an emergency tracheotomy or laryngotomy would be advisable to supply the oxygen by this route. It might be objected that rather than the performance of such a radical procedure a reduction of intracranial tension with relief of medullary compression might be brought about by a ventricular tap or by intravenously administered hypertonic saline solution or dextrose, but such means would appear less certain and would produce only transitory effects. In the syndrome of compression of the posterior fossa therefore the indication would appear to be an extensive mechanical relief of pressure.

Malaria—Fairley cites a case which was an instance of infection with the fourth species of malarial parasite—that is *Plasmodium ovale* Stephens 1922—contracted during a tour in West Africa. Throughout his stay in Africa the patient had consistently taken prophylactic quinine, and this is the probable reason for the long incubation period unless a previous fever of two days duration can be interpreted as representing the primary malarial attack. The species of parasite was suspected on clinical grounds when the laboratory reported atypical quartan malaria, when the patient though at the onset manifesting quartan, later showed a tertian periodicity. Another peculiar feature was the late time of onset of the rigors which occurred between 6.30 and 7.30 p.m. whereas malarial fever generally commences before or about midday. The biochemical and hematologic observations were of interest. Hemoglobinemia was not evident at the time the plasma was examined but the urobilinuria and hyperbilirubinemia indicated that the blood destruction usually associated with malarial fever was going on. Bile pigments in the urine are unusual in malarial fever and probably originated from a mild toxic hepatitis in this instance. The reticulocytosis reached a maximum of 63 per cent eight days after the initiation of specific treatment. This is a fall in malaria for once the parasites are controlled or destroyed regenerative activity of the bone marrow results in reticulocytosis and new blood formation.

Rift Valley Fever—Mackenzie inoculated four mice with virus of Rift Valley fever and two days later one of these showed definite symptoms associated with the infection and was therefore killed. The heart blood was drawn off and two drops of the blood were added to each of a series of 50 cc. Erlenmeyer flasks containing 5 cc. of Tyrodes solution and chick embryo made up in the proportions used by Rivers. The flasks were then plugged and incubated at 37°C. for three days. Three days later, subcultures were made by transferring 0.2 cc. of the fluid from each of the original flasks into a new series thus giving a dilution of 1/25. At the same time, two flasks were selected at random and the titer of the virus in them was estimated by the inoculation of progressive dilutions into mice. From the remaining flasks two mice each were inoculated. The culture fluid, diluted 1/10,000 in one case killed three mice out of three and in the other case one mouse out of three, and this may be taken as the approximate titer of the fluid. When the next subculture was made one flask was set aside in the cold while the rest were incubated and then, after three days the titer of the uninoculated flask was compared with one of those that had been kept at 37°C. The titer of the virus in the incubated flask was considerably the greater. After this subcultures were made every three or four days and, when the experiment was voluntarily stopped it had reached the twelfth subculture. At the eleventh subculture the titer was again estimated and it was seen that the titer of the virus remained more or less constant. After the twelfth subculture the fluid from three of the incubated flasks was pooled, filtered through a Seitz filter and inoculated into mice, which died in the usual time with symptoms of Rift Valley fever confirmed by histologic examination of the livers. As the dilution of the inoculum in the primary culture and in each of the twelve subcultures has been approximately 1/25 the final dilution of the infected blood must be about 1 in 15×10^{12} . Infected blood diluted with Tyrode solution alone or with broth or serum and incubated at 37°C. shows a gradual loss of titer and is generally completely inactive in about seventy-two hours. The author claims that he has obtained a true increase in virus of Rift Valley fever by *in vitro* cultivation and that the activity of the subcultures cannot be explained in any other way.

Treatment of Hemorrhage in Placenta Praevia—Paucot and Reeb present a critical evaluation of the results obtained by numerous authors, including themselves, with different methods of treatment of hemorrhages in placenta praevia. The systematic practice of surgical methods is not justified, because the majority of cases are amenable to a wide rupture of the fetal membranes. When rupture of the membranes assures hemostasis and is followed by spontaneous delivery, this method is unequaled from the standpoint of maternal safety, although it is mediocre for the child. In grave cases in which this method is inapplicable or ineffective, low cesarean section has proved to be superior to any other obstetric or surgical procedure in safeguarding the life of the mother and that of the child. The indications for low cesarean section are (1) the necessity of checking immediately the hemorrhages of gestation or labor, independent of the condition of the cervix, of the type of insertion of the placenta or of the life of the fetus, (2) the difficulties inherent in the cervix in the type of insertion of the placenta, and in complex dystocias, (3) failure of obstetric treatment, and (4) desire to save the life of the infant. In cases of suspected infection, low cesarean section may also be employed without grave risk for the mother but a confirmed infection and the poor general condition of the woman often demand hysterectomy (subtotal, Porro) in preference to other complex obstetric methods. Spinal anesthesia is preferred because of its hemostatic properties, if the minimum arterial tension is nearly normal, in hypotension, ether anesthesia is preferable. Preoperative or postoperative blood transfusion is an effective treatment of hemorrhage or shock.

Treatment of Empyema of Infancy—Costa Staricco treated eighteen patients suffering from empyema and ranging in age from a few months to 5 years. Of these, sixteen were metapneumonic and two were parapneumonic. Bacteriologic examination demonstrated the diplococcus in sixteen patients and the diplostaphylococcus in two. All but one showed complete recovery after treatment. Surgical intervention is seldom required after treatment. Only three of the eighteen patients necessitated subsequent operation: two had advanced bilateral empyema and the third a nursing aged 11 months, had pleuropneumonia of the right upper lobe and concomitant empyema throughout the pleural cavity. The author's technic consisted of aspiration of the largest possible amount of pus with a trocar or large needle attached to a syringe and introduction of a solution of 0.1 per cent of chloride of 3.6 diamine 10 methylacridine at body temperature. The pleural cavity is washed with this solution and afterward all the lavage fluid is drained out. Still without removing the needle from 10 to 15 cc of a 0.5 per cent solution of acridine or an amount of this solution corresponding to 0.005 Gm of acridine per kilogram of body weight is injected intrapleurally. Generally from three to four injections are given five or six days apart. If meanwhile examination of the thorax reveals rapid reproduction of the pus simple evacuating punctures should be made. Following treatment the pus becomes dense gelatinous and sterile and disappears gradually. The temperature usually decreases after the first injection and general body improvement occurs. The author highly recommends this treatment for empyema.

Bile Peritonitis—Todor reports two cases of bile peritonitis without visible perforation. It has been established experimentally that bile can pass through a pathologically altered gallbladder wall but not through a normal wall. It appears that bile can pass into the peritoneal cavity under the following clinical conditions through a microscopic perforation of the extrahepatic bile tracts, especially of the gallbladder, from an anomalous duct in the hilus of the liver from a perforation of a superficial intrahepatic bile duct and from changes in the permeability of the bile ducts. The perforation may be healed at the time the exploration is made. Changes in the wall of the gallbladder may be brought about by pancreatitis. Transudation of sterile bile into the peritoneal cavity may result in an acute cholangitis or in a cachectic choline poisoning leading slowly to death. The process may become encapsulated and heal. Infected bile may lead to fulminant peritonitis or to a chronic form with nephritis and characteristic bradycardia and fall in the blood pressure. The question as to which factor in the sterile bile acts as a toxic factor has not been definitely solved, the evidence pointing to bile acids and their salts.

A Pressoreceptor Nervous System—Braeucker demonstrated in his studies on rabbits that the concept of a pressoreceptor nervous system as consisting of four nerves, the two superior cardiac nerves and the two carotid nerves branches of the glossopharyngeus, is incomplete. He found the system to be represented anatomically by a very complex network of periaxillary plexuses which spread from the cardiac plexus over the arch of the aorta, the common carotid artery, its bifurcation and its branches. The author concludes from his sectioning experiments that the afferent pressoreceptor paths are not limited to the four nerves as previously considered but are a part of the peripheral vegetative nervous system of the neck and the upper part of the thorax. He found the same anatomic relations in man with the additional observation that the pressoreceptor nervous system here extends to the thyroid gland and forms a plexus within the so-called thyroid capsule. Central stimulation of sectioned ends of pressoreceptor nerves causes a twofold stimulating effect on the medullary centers—vaso dilatation and slowing of the heart. The significance of these facts in relation to surgery of the deep structures of the neck is evident. The question of the possible reflex effect of trauma to the nerve plexus of the thyroid capsule in the course of delivery and resection of the gland presents itself. The author found that signs of bulbar paralysis developing in his animals in the course of dissection of the neck could be successfully combated by a timely venesection. He advances the theory that sudden death in the course of a thyroidectomy, and the so-called postoperative thyrotoxic crises are reflex phenomena resulting from irritation of pressoreceptor nerves. He reports the histories of five patients with thyrotoxicosis, who developed paralysis of the bulbar centers. Prompt venesection, with withdrawal of from 200 to 300 cc of blood from the anterior jugular vein gave immediate relief of these symptoms. He believes that the remarkable effect of venesection is due to lowering of the blood pressure and reflex diminution of irritative stimuli to the entire pressoreceptor system. To avoid undue irritation of the pressoreceptor paths in the course of a thyroidectomy general anesthesia should be used with addition of local procaine hydrochloride blocking of the pressoreceptor paths. He injects the solution of procaine hydrochloride at the area of bifurcation of the common carotid artery, about the stem of the vagus (lower third of the ganglion nodosum) and into the area of the upper cervical ganglion and the stellate ganglion. Dangerous reactions occurring in spite of these measures are best treated by prompt venesection.

Argentaffine Cells in Pernicious Anemia—Eros studied the argentaffine cell system in the gastro-intestinal tract and was convinced that this cell system produces a hormone-like substance of vital significance. In examining the intestine of persons who had died from pernicious anemia, he found that the argentaffine system of the intestine is greatly atrophied. Not only is the number of argentaffine cells considerably reduced but their size has also changed and they contain fewer granules. He deduces from this observation that the argentaffine cell system both of the gastro-intestinal tract and of certain endocrine organs plays a part in hematopoiesis. He relates animal experiments by which he effected a considerable increase in the argentaffine cells. The intestinal tract of these animals was then used for preparing extracts, the administration of which to animals demonstrated that they promote blood formation and inhibit the development of anemia. The author realizes that a conclusive demonstration of the efficacy of the extract can be obtained only on human subjects. He tried it on a number of persons and found that it promotes blood formation. Extremely small doses of the extract effected an increase in erythrocytes, leukocytes and reticulocytes, while larger doses did not produce an increase and even were followed by a reduction in the formed elements of the blood. Further studies on this problem are still under way.

Leukemic Diseases of Skin—In a classification of the leukemic dermatoses, Arzt shows that this subject is highly complicated. Corresponding to the two types of leukopoietic tissues, the leukemic dermatoses are differentiated into lymphatic and myeloid processes. Discussing the lymphatic processes he directs attention to leukemic tumors that develop in the region of the superciliary arch and may become manifest in prominent ridges. The ears and particularly the nose may become involved and a considerable increase in the size of the nose is a symptom that is especially likely to make the observer think of leukemia. If the process spreads further, the whole face and even the entire head may become involved and the characteristic aspects of leontiasis result. This leontiasis should be differentiated from the leontiasis that occurs in leprosy, because they differ in their etiology. Although the face is the site of predilection for leukemic tumors they may occur at other sites particularly in the region of the elbow of the mammae and of the penis. The decision whether a tumor is of a leukemic nature has to be made as a rule by the histologic demonstration of a leukemic blood picture but the histologic examination may prove helpful. Another cutaneous manifestation of leukemia which differs from the localized tumors is universal lymphomatosis of the skin. Other terms applied to this condition are leukemia cutis diffusa and leukemic erythrodermia. The author thinks that in every erythrodermia the possibility of an underlying leukemia should be considered particularly if pruritus exists. He discusses the comparatively rare occurrence of a leukemic exanthem. It becomes manifest as a small papular exanthem and is localized especially on the trunk. The differential diagnosis of this disorder is difficult and must be based on accompanying symptoms such as a generalized swelling of the lymph nodes. There are other cutaneous manifestations or chronic leukemic lymphomatoses which lack characteristic clinical pictures and may appear as dermatitides, eczemas, erythemas, vesicular dermatoses, urticarial exanthems and cutaneous hemorrhages. The blood picture is generally the only means of diagnosing the disturbance correctly. Only lymphatic leukemia has more or less typical clinical aspects. In discussing the myeloid forms of leukemia the author states that the leukemic tumor of the skin is characterized by the fact that the tumor is the first

But here the face is not the site of predilection and the tumors reach at the most the size of a nut. A predisposition to hemorrhages is likewise noticeable. The author concludes by emphasizing once more the diagnostic significance of pruritus and of the hemogram.

Nodular Myolysis of Tongue—Roffo describes a lesion of the tongue, which he designates as nodular myolysis. He states that, among the 800 cases of lingual cancers that came under his observation within the last four years, this is the second one of this nature. The anamnesis revealed that three years ago the woman first noted a nodule the size of a lentil, which gradually increased to the size of an almond. The growth was on the right side of the tongue and its longest diameter was parallel to the median groove. The nodule was hard but painless and was covered with mucous membrane of normal appearance. Removal of the nodule was followed by cure. The histologic examination disclosed that the lesion involved only the striated muscle fibers of the tongue. It was characterized by loss of striation, change in the structure of the contractile substance, destruction of the fibrils, lysis and complete vacuolation of the fibers. The author assumes a traumatic etiology, since other causes could not be detected.

Neuroma and Carcinoid Tumor of Vermiform Appendix—In all so-called chronic or subacute forms of appendicitis in which the removed appendix shows no microscopic or microscopic evidence of an inflammatory process of the mucosa, Hellner advises a search for alterations in the nervous structure of the appendix. He reports several such instances in which he found neuromas in the submucosal layer of the appendix. In addition there is found at times a tumor formation usually referred to in the literature as carcinoid tumor of the appendix. Ehrlich of Kharkov and Masson of France have independently of one another advanced the neurogenic theory of the origin of this tumor. In his histologic studies, Masson has demonstrated the close relationship of the epithelial cells of the tumor to the nervous elements which appears to establish a relationship between the neuromas and the so called carcinoid tumor. Considered from a histopathologic point of view the tumor is a neuro-ectodermal blastoma. This concept is favored by its benign nature, the presence of neuromatous alterations in the submucosal layer and its close relationship to the nerve plexuses of the mucosal and the muscular layers. These tumors have no relation to carcinoma. They are not known to give rise to metastases. The author's patients who were operated on two and four years ago remained well. These tumors are sometimes found accidentally in the course of an abdominal operation but more often are operated on because of an acute, subacute or chronic appendicitis. He regards the infection of the mucosa here as secondary to the obstruction of the lumen of the appendix by the tumor with resulting stasis.

and infection. The author doubts the existence of true carcinoma of the appendix except as a secondary metastatic manifestation.

Advances in Operative Treatment of Ileus—Philpowitz points out that the mortality rate in ileus fluctuates in published statistics between 40 and 60 per cent. The first notable lowering was reported by Morton of Rochester and by himself. Morton's mortality was 28.5 per cent, while the author's amounted to 27.7 per cent. In the last five years the author operated on forty-five patients with ileus and further reduced his mortality rate to 15.5 per cent. In analyzing the causes contributing to the improvement in results, he emphasizes earlier diagnosis and immediate operation. He objects to roentgenographic studies and the employment of high enemas. The short time required for the preparation of the operation is utilized to wash out the patient's stomach, to administer cardiac stimulants and to introduce 0.5 liter of physiologic solution of sodium chloride by hypodermoclysis. However, the main factor in the improvement of the results is the exclusive use of spinal anesthesia practiced by the author for the last six years. The ideal relaxation of the abdominal muscles obtained by this method of anesthesia permits of an easy exploration of the abdominal contents for the purpose of rapid orientation. The complete paralysis of the anal sphincter and the increased peristalsis following on the release of the obstructed intestine bring about an immediate and satisfactory emptying of the intestine by the natural route. The reposition of the abdominal contents and the closure of the abdominal incision are thus rendered easy. Because the patient is conscious, he is in no danger of aspirating his stomach contents. Surgical procedures on an emptied and now contracted intestine are easier and safer. It was the author's experience that these sick, frequently dehydrated and toxic patients tolerated well the spinal anesthesia. He considers the method by which the obstructed intestine is relieved by an enterostomy without investigation of the cause of obstruction faulty and dangerous. Primary resection should be performed by the expert and only under most favorable conditions, otherwise one should be content with the immediate life-saving procedure only. Early operation, the use of spinal anesthesia and postoperative intravenous infusion of hypertonic salt solution are the three main measures responsible for the improvement in operative results of ileus.

 *Pulmonary Suppuration Due to Aspiration of Foreign Body. A. L. Ginzburg—p. 242

Problems in Biliary Surgery—On the basis of 165 operations on the biliary tracts, Brzhozovskiy analyzes the surgical problem in this field. He considers stasis of the gallbladder an early stage of acalculous cholecystitis. Stasis of the gallbladder and acalculous and calculous forms of cholecystitis represent successive stages of the same inflammatory process. Operations in the acute stage are permissible and cholecystectomy is the operation of choice. Primary closure of the abdomen without drainage is indicated in properly selected cases of cholecystectomy and choledochotomy. Cholecystectomy in uncomplicated cases has a negligible mortality. A decisive lowering of mortality as well as improvement in the late results, is to be expected only from earlier operations. Recurrence of pain after operations is caused principally by the persistence of infection in the biliary tracts.

Pulmonary Suppuration Due to Aspiration of Foreign Body—Ginzburg states that suppurative processes in the lung the result of aspiration of foreign bodies are not infrequent. They occur in all ages but with greatest frequency in childhood. The more common localization is the right lung because aspiration of foreign bodies takes place as a rule by way of

the right bronchus. The suppurative process may later extend to the opposite lung, as occurred in one of the author's cases. The recognition of the cause of suppuration in these cases depends primarily on the history and the slow, insidious development of the process frequently interpreted as a recurring pneumonia. One should not rely entirely on roentgenographic data. Any suspicion of a foreign body warrants a consultation with a laryngologist. The amount of involvement depends on the nature of the foreign body and the immunobiologic properties of the invaded organism. The treatment consists of bronchoscopic removal of the foreign body with secondary aspiration of the abscess. Even the neglected cases can be cured, as a rule. Surgical intervention becomes necessary in exceptional cases only.

Syphilitic Disorders of Central Nervous System

Geert-Jørgensen and his associates discuss the clinical symptoms and serologic changes in about 900 cases of dementia paralytica on their first hospitalization and in other cases syphilitic mental disorder or mental disturbances in patients having syphilis, with especial attention to the possibility of bringing about earlier treatment of at least part of the case of dementia paralytica. They state that there is usually a preparalytic stage in two thirds of the cases of dementia paralytica, in men and in women, symptoms of a change in the patient's mental attitude in daily life were seen for from three months to three or four years. Every noticeable psych change in persons between 35 and 45, especially if there is no information of syphilitic infection, should arouse suspicion of a beginning dementia paralytica (Wimmer). A negative Wassermann reaction in the blood of an older patient with syphilis does not testify against a developing paralytic process, a change in the patient's mental attitude should be watched for. In the objective examination especial attention should be paid to changes in the pupils, disturbances of speech, fibrillations about the mouth and of the tongue, facial expression and changes in reflexes. In suspected beginning paralysis or case of doubt, examination of the spinal fluid is advised. The paralytic changes consist of those due to inflammatory reaction and those due to destruction of nervous elements, the latter causing the permanent psychic defect. Examples are given to show that these changes are not always parallel, and the dissociation between the serologic picture and the clinical picture is particularly evident in the fever-treated cases. Treatment of a beginning dementia paralytica with the usual antisyphilitic agents is not only useless but causes the time for fever treatment to be missed and gives the paralytic process a chance to produce irreparable damage in the central nervous system. For good and lasting results in the treatment of dementia paralytica treatment as early as possible, preferably in the preparalytic stage is urged.

Progressive Lipodystrophy—The father and a paternal aunt of Brächner-Mortensen's patient a woman aged 21 are presenting typical Simons' progressive lipodystrophy, a reported to have had a similar disease when young and have regained a normal appearance in their late twenties. The case is accompanied by some ovarian hypofunction, slight hypertrichosis and petit mal.
